Same objection and notice.

A. No, sir.

X Q. 296. Were you aware at the time of the Herald article of December 21st, 1879?

Same objection and notice.

A. I believe I was.

1134 X Q. 297. Were you aware of the article published in Scribner's Monthly for February, 1880, at the time of its publication?

Same objection and notice.

A. I do not remember, but I think it probable.

Defendant's counsel offers in evidence a copy of the N. Y. Herald, of December 21, 1879, containing an article on Mr. Edison's electric light invention, and the same is marked "Defendant's Exhibit Herald Article of December 21, 1879, July 8, 1887."

Defendant's counsel also offers in evidence Scribner's Monthly, for February, 1880, and the same is marked "Defendant's Exhibit Scribner's Monthly, July 8, 1887."

Exhibits objected to as irrelevant, incompetent, immaterial, and not proper cross-examination, and not proved as having been published.

X Q. 298. Were you aware at the time, or did you read at the time, the publication in the New York Sun of December 22, 1879, of the article entitled "Electrician Sawyer's challenge to Electrician Edison"?

Same objection and notice as to last question.

A. I think that I was, Mr. Sawyer, I think, calling attention to it soon after its publication.

X Q. 299. Did you read at the time, or were you aware of the publication in the Sun of January 5, 1880, of the article entitled, "Mr. Edison challenged by Mr. Sawyer"?

Same objection and notice.

A. I do not remember now.

X Q. 300. Did you read at the time, or were you aware of Mr. Sawyer's letter to the Herald, headed: "Sawyer on Edison and the Herald," and published in the Herald on December 24, 1879?

Same objection and notice.

A. My attention was called to that article.

1135 X Q. 301. Were you aware at the time, or did you read Mr. Sawyer's letter to the Herald of January 5, 1880, headed "78 Walker street"?

Same objections and notice.

A. I don't know; I don't recollect.

X Q. 302. Did you read Mr. Sawyer's letter, or were you aware of the publication of such letter addressed to the editor of the Herald, January 6, 1880, and entitled "Mr. Sawyer's exhibitorium"?

Same objection and notice.

A. I don't recollect.

X Q. 303. Were you aware at the time of its publication, or did you read Sawyer's book on electric lighting?

Same objection and notice.

A. I saw the book some time after its publication. I glanced at the book, but never read it, to the best of my recollection.

X Q. 304. Did you, prior to the application for the patent in suit, have any conversation with Mr. Sawyer regarding these publications, or any of them?

Same objection and notice.

A. My impression is that I did, in regard to the first one mentioned, that of the Sun, of December 22, 1879, or of the one in the Herald of December 24th, or both of them. I don't recollect any conversation in regard to the others.

X Q. 305. These two articles that you remember conversing with Mr. Sawyer about, had you read at the time of the conversation?

Same objection and notice.

A. I think so, perhaps not at the first allusion to them. It may have been part of the same conversation.

X Q. 306. Did Mr. Sawyer in these conversations give you to understand that the letters thus published had been written by him?

Same objection and notice.

1136 A. I think Mr. Sawyer asked me if I had seen the paper. My impression of the conversation is that I learned from him that he had caused their publication.

X Q. 307. After the formation of the Electro Dynamic Light Co. on July 11, 1878, did that company have ample means at its disposal to apply for and obtain patents for such inventions as you thought of value?

Same objection and notice.

A. I think it did; certainly by the 1st of September or October following it had.

X Q. 308. Had Sawyer & Man jointly ample means with which to apply for patents on inventions regarded by them as valuable, prior to the formation of the company?

Same objection and notice.

A. I had. Mr. Sawyer had not.

X Q. 309. During your connection with Sawyer, up to the first part of 1879, what were your habits with reference to applying for patents, separately, or you and he jointly?

Same objection and notice.

A. Some were applied for in our joint names, some in the name of Sawyer alone, and I think some, perhaps only one, in my own name, according to the advice of counsel, and the manner of invention whether joint or separate, I don't recollect.

X Q. 310. Were you diligent in applying for your patents on such inventions as were made?

Same objection and notice.

A. I don't think we were.

X Q. 311. Had you not ample means of obtaining such patents as you desired to apply for?

Same objection and notice.

A. No, not at first. Mr. Sawyer was to pay for taking out the patents, and had not much means, and was very economical in his expenditure for patents.

1137 X Q. 312. After your association with Mr. Sawyer, were not you and he amply able to pay for taking out such patents as you thought necessary?

Same objection and notice.

A. I was able to pay for any patent that I wanted to take out; Mr. Sawyer was not.

X Q 313. How about Sawyer and Man jointly?

Same objection and notice.

A. As to Sawyer and Man jointly, we promptly applied for what we considered the main patents. A fixed sum was agreed upon to be paid to Mr. Sawyer, out of which he was to pay for the patents. He was poor, and objected to taking out many patents, and said that after the company was organized all the patents that we needed could be taken out, and they were. I could have personally paid for patents at any time, but did not feel inclined to do so under these circumstances other than we did.

X Q. 314. Am I correct in understanding that upon making inventions which you considered of controlling importance, you promptly applied for patents for the same?

Same objection and notice.

A. Our first applications for patents were made from the 10th to the 15th of May, 1878, as I recollect, and from that time forward until some time in June we made applications for what we then thought the most important things that we had invented from the time we went to work together in February previous, but we knew we were not applying for all, and our judgment as to what were the most important things, in the light of subsequent events, might not be deemed very good.

X Q. 315. After the formation of the Electro Dynamic Light Co., was that company to pay for the taking out of patents?

Same objections and notice.

A. Yes, sir; such as were taken out after its formation?

1138 X Q. 316. Did Sawyer's objection to taking out patents on inventions that were considered of minor importance by reason of his poverty, apply to that company?

Same objection and notice.

A. No, I don't think it applied to that company, that is, I don't mean that it was objecting to taking out patents.

X Q. 317. Am I correct in understanding that the company had ample means to patent such inventions as you or Mr. Sawyer thought desirable?

Same objection and notice.

A. Yes, as soon as arrangements for money were made, which was not until September or October, 1878.

X Q. 318. After that period were they not amply able to apply for and obtain such patents as were considered valuable?

Same objections and notice.

A. Yes, sir.

Adjourned till Monday the 11th inst., at 11 a. m.

MONDAY, *July* 11*th*, 1887.

Met pursuant to adjournment.

Present, counsel as before, and the cross-examination of Mr. MAN continued as follows:

X Q. 318*a*. What is your present recollection as to whether, under the arrangement with Mr. Cheever, the Electro Dynamic Light Company were to have a right to use the invention?

—. ——.

X Q. 318*b*. Was this expressed in the written agreement?

Same objections and notice.

A. My recollection of the matter is that the Electro Dynamic Light Company were to have the right to use the invention, or some part of it, by an understanding with Mr. Cheever.

Same objection and notice.

1139 A. My impression is it was not. My recollection is not clear about it, though.

X Q. 318*c*. Are you quite positive you signed the application at Mr. Cheever's office?

Same objection and notice.

A. Yes, that is my recollection of it.

X Q. 318*d*. Do you now remember who procured the signature of Mr. Wallace to the paper assenting to the appointment of Mr. Baldwin as attorney, witnessed by you and dated January 8th?

Same objection and notice.

A. I don't recollect.

Defendant's counsel offer in evidence letters patent No. 205,144 to Sawyer & Man, dated June 18, 1878, and applied for May 16, 1878, and the same are marked Defendant's Exhibit Sawyer-Man Patent No. 205,144, July 20, 1887.

Also letters patent 205,303, to Sawyer & Man, dated June 25, 1878, applied for May 31, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent 205,303, July 20, 1887.

Also letters patent No. 205,305, to Sawyer & Man, dated June 25, 1878, application filed May 25, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent No. 205,305, July 20, 1887.

Also letters patent to Sawyer & Man, No. 210,152, dated November 19, 1878, application filed Oct. 19, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent No. 210,152, July 20, 1887.

Also letters patent to Sawyer & Man No. 210,809, of December 10, 1878, application filed November 5, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent No. 210,809, July 20, 1887.

Also letters patent to Sawyer & Man, No. 211,262 of January 7, 1879, application filed October 17, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent 211,262, July 20, 1887.

1140 Also letters patent to Albon Man, No. 227,118 of May 4, 1880, application filed March 31, 1880, and the same is marked Defendant's Exhibit Albon Man Patent 227,118, July 20, 1887.

Also letters patent to Sawyer & Man, No. 229,335, dated June 29, 1880, application filed November 29, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent No. 229,335, July 20, 1887.

Also letters patent to Sawyer & Man, No. 229,476 of June 29, 1880, application filed June 25, 1878, and the same is marked Defendant's Exhibit Sawyer-Man Patent 229,476, July 20, 1887.

X Q. 319. When did you first meet William E. Sawyer?

A. Some time in January, 1878, at my house in Brooklyn.

X Q. 320. How did this meeting come about, and at whose introduction?

A. I think through Gen. E. L. Hayes, and perhaps William H. Church.

X Q. 321. State what led to your introduction to Mr. Sawyer, and with what object the introduction was brought about?

A. I had been talking to Mr. Hayes, my neighbor, about electricity, and especially the subject of electric lights; he had come to know Mr. Sawyer, or to know of him, as I understood, through Mr. Church. One, or both of them called upon me and obtained permission to bring Mr. Sawyer to see me; I think first, upon the plea that we were mutually interested in the general subject of electricity, and that it would be interesting to know one another, and might be mutually advantageous.

X Q. 322. Do you mean to be understood that your introduction to Mr. Sawyer was bought about solely by a desire to make personally acquainted two gentlemen interested in the general subject of electricity?

1141 A. So far as I was concerned, yes; I have reason to believe that Mr. Sawyer hoped, by means of the introduction, to obtain financial assistance from me in carrying out some plans he had in mind.

X Q. 323. Please state what those plans were.

A. A plan, or plans for electric distribution, and some system of arc lighting; I do not think I ever got a definite idea of his exact plans in reference to arc lighting, but he had, before he came to see me, taken out a patent, or patents for electrical distribution.

X Q. 324. Was that his entire plan as you then understood it?

A. I do not recollect anything else.

X Q. 325. So far as Mr. Church or Mr. Hayes were concerned, were they at this time aware that Sawyer's object in meeting you was for the purpose of securing your financial assistance for perfecting or developing the plans referred to?

A. I don't know; I suppose so, or something like that, or that I might advise him or direct him to others, but Mr. Church knew that I would not interest myself in any way in the scheme he outlined to me of arc lighting, as I told him so.

X Q. 326. In the interview between yourself and Mr. Sawyer, when he was presented to you by Mr. Church, did he explain to you any plans of his in which he desired your assistance, or did your conversation have *on* reference to business matters?

A. Mr. Sawyer brought with him some diagrams showing his plans of electric distribution and explained them to me, and also spoke of some ideas that he had in regard to electric lamps, and we talked upon that and general electrical subjects, during the course of which I said to him that I did not want to interest myself in the subject, especially in the then present condition of electric lights; the light of which he talked being the arc light; in
1142 the course of the conversation I had taken occasion to state
that Mr. Church had told me that he (Sawyer) having heard of my interest in electrical subjects had hopes that I would interest myself or introduce him to others who would take interest in his projects; he in some measure or in some way assented to this, and said anyway whether I interested myself with him or not he was glad to talk with me. The subject of incandescent electric lights was introduced by me, and I asked Mr. Sawyer what he knew in regard to the subject-matter; he referred to the experiments he had made, and referred especially to those of Lodyguine and King and some others of whom I had heard; we discussed their attempts, and I expressed the opinion that that was the true method of electric lighting, and the only one suitable for interior illumination, and that arc lights were only fit for out of doors and large places; I think Mr. Sawyer at this interview, or at one immediately afterwards within a day or two, told me that he thought he could make an incandescent lamp or permanent lamp, as we called it, in which I had expressed great interest, and then told me he was going to try it. I certainly intimated to him that I might be willing to interest myself in a project of that kind financially, in connection with his system of distribution and other plans of which he had talked, and of which I talked with him.

X Q. 327. When, after the interview referred to in your 326th answer, did you next see Mr. Sawyer, and where?

A. We met almost every day after our first interview at my house; several times at my house, and afterwards at my office in New York.

X Q. 328. What caused these interviews?

A. An appointment at each meeting for a subsequent meeting.

X Q. 329. Was Mr. Sawyer endeavoring to interest you financially in the development of his plans?

A. Yes; both that and to discuss plans with me—plans relating to electric lighting by incandescence.

1143 X Q. 330. Did these plans relate to the invention of a lamp by Sawyer, or to the securing of financial aid for the conduct of experiments in that direction?

A. Mr. Sawyer wanted to make experiments; wanted my advice and assistance as to the apparatus for the experiments, and wanted that I should advance the money for the experiments and be interested in whatever should grow out of them; whether he came to me solely for the purpose of money considerations, after the first I could not know, except that he did not so express himself, but was on the contrary continually asking advice and suggestions from me. I had suggested the matter of incandescent lighting at first, and he seemed very much taken with it.

X Q. 331. As I understand you in your first interview with Mr. Sawyer, he desired your financial assistance in developing his plans of distribution and electric lamps, which you understood to be arc lights, and that you refused your co-operation, stating that you did not believe in arc lights in the then condition of the art, but that you did believe in incandescent lamps of the type of those made by Lodyguine and King, and that you would be willing to further any plan for the development of his system of distribution in the development of those lamps. Am I correct in so understanding you?

A. I do not mean to be understood in the exact manner of your statement in the question.

X Q. 332. In what respect is my statement incorrect?

A. I simply meant to say that I intimated to Mr. Sawyer that I did not want to be interested in his plans as he then presented them to me, and that they had reference to a system of distribution, and of arc lamps in which I had no confidence for purposes of interior illumination and general use in the then condition of the art. I did not commend any type of lamp like Lodyguine's or King's, and only intimated to Mr. Sawyer, after his saying that he
1144 thought he could make a permanent lamp, that I might possibly take an interest in such a thing.

X Q. 333. Is it, then, true that Sawyer stated to you that he thought he could make a permanent or incandescent lamp, and that you intimated to him that you might aid him financially in his enterprise?

A. Substantially, yes, to some small extent, upon condition that I saw any probability of success in his experiments proposed, or to be proposed.

X Q. 334. Is it also true that, after this interview, Mr. Sawyer was continually calling on you, endeavoring to secure your financial aid for the conduct of experiments on incandescent lamps?

A. Your question implies what is true, and what is not true. Mr. Sawyer was calling upon me to get my views of his projects with reference to the experiments of which he wanted and expected me bear the expense. So far as this expense was concerned, he was seeking my financial aid; so far as he was seeking criticism, advice and suggestions from me, he was not. However, this continued but a short time, when, seeing some prospect of success, I agreed to bear the expense of experiments which were immediately commenced.

X Q. 335. When was the agreement made, and was it *it* in writing?

A. I cannot give the exact date, and I do not recollect whether the matter was put in writing at first or shortly afterwards. It was put in writing about the time it was made.

X Q. 336. Have you that agreement, or a copy?

A. I have neither the original nor a copy, and neither is within my control. The agreement as referred to, is in my examination-in-chief; it is dated February 15, 1878, and is quoted in my examination-in-chief, in answer to question 32.

X Q. 337. At what place were experiments first performed
1145 relating to incandescent lamps after the making of the agreement referred to?

A. My recollection is at No. 43 Centre street, New York city.

X Q. 338. Had any experiment been conducted prior to the experiments conducted at No. 43 Centre street?

A. Yes; I think one, and that may have been subsequent to the making of the agreement referred to. I am not positive.

X Q. 339. What was the experiment referred to? Where, and by whom was it performed?

A. At the Coal and Iron Exchange, corner Church and Cortlandt streets, New York city. The experiment consisted in heating up a piece of platinum, or a piece of carbon, I am not sure which, in a bottle filled with ordinary illuminating gas from the gas main, by means of an electric current, and was performed by Mr. Sawyer, assisted by myself. I think Mr. George Sawyer, his brother, was present part of the time, but I am not sure; if he were present, that was all.

X Q. 340. How did you come to be a witness of, or a participant in this experiment?

A. By prearrangement with Mr. Sawyer.

X Q. 341. Please to state what was said by Mr. Sawyer, and fully, what led to your going to the place referred to, to witness or take part in this experiment?

A. I do not recollect the words of the conversation at this time, but only the substance of what took place, that was: In the absence of a laboratory, we could not make any gas; we had no means — exhaustions; no means of preserving a vacuum, or partial vacuum, if obtained; no dynamo for the production of electricity, and under the circumstances, our thoughts reverted to the ordinary gas used for illumination, which by its pressure, could be kept flowing through the vessel to the exclusion of the atmospheric air. Mr. Sawyer said that there was an old bat-
1146 tery at his office which he thought we could rig up to get a current, so we drew diagrams of the holders for the carbon, and Mr. Sawyer's father, who was a machinist, made the holder and cap for the neck of the bottle. Mr. Sawyer himself rigged up the old battery, and when he had got it ready I went down to his place the same day, after office hours, and he and I tried the experiment.

X Q. 341*a*. Do you mean to say that the subject-matter of this experiment had been a matter of discussion between yourself and Mr. Sawyer?

A. I do.

X Q. 342. And that you and he had discussed the general character of the lamp which was made and tried?

A. Yes, I do.

X Q. 343. Is it not the fact that you went to the Coal and Iron Exchange on the day mentioned rather to see a lamp which Mr.

Sawyer had made, and wished to show you, than to take part in the experiment?

A. That is not a correct statement of my recollection of it. It is true, that when I went to the place I did not expect or intend to take any part in the experiment personally, but it is true also, that the whole matter was planned, discussed and talked over between Mr. Sawyer and myself before the experiment was made. It is also true that I considered the matter as a whole, Mr. Sawyer's matter, and not mine, although I had advised and planned with him about it.

X Q. 344. When you went there, was the so-called lamp already put together and charged?

A. No, sir; nor was it there when I got there.

X Q. 345. Please state all that was done, so far as this so-called lamp was concerned, by yourself and Mr. Sawyer on the day and at the place referred to.

A. I think Mr. Sawyer's brother, George, came to my office, and told me that his brother would like to have me call upon
1147 him, giving me his place in the Coal and Iron Exchange,
after I got through with my business, according to some previous arrangement. At all events, I went, found Mr. Sawyer and his brother there; but none of the apparatus ready. Sawyer set his brother George to filling the battery, busied himself in hunting around for some of the apparatus, I forget what, perhaps some of the rubber tubing or wire, that was to be used. I was in a hurry, and he sent George off somewhere to get the holders and cap. To hasten matters, I took hold and filled the battery. George was gone so long that Mr. Sawyer went down after him, and brought back the cap, with its holder, and a bottle. I think George did not return with him. The thing was crude and unfinished. There was no stop-cocks; so we tied up the rubber tubing, connected to the inlets and outlet tubes of the lamp, if it may be called a lamp. After allowing the gas to flow into and out of the bottle until the air was all driven out it was filled with gas. Then we turned on the current, and heated up the incandescent conductor between the holders, and I think we repeated the operation twice or possibly three times, until we finally melted the junction between the incandescent portion and the holder, when the thing went out.

X Q. 346. Please make a drawing of the so-called lamp to which you have referred?

A. I do.

X Q. 347. Were the globes of the shape shown by you?

A. I think it was a Florence flask about that shape. There was only one, and I think I got it for Mr. Sawyer. By that shape, I mean the shape of Florence flask.

X Q. 348. What was the size and character of the incandescent conductor?

A. Its size, according to my recollection, was about one-sixteenth of an inch, possibly a little larger in diameter, or possibly
1148 less, and from five-eighths to three-fourths of an inch in length.
My impression is that it was a broken, angular splinter of gas-retort carbon.

X Q. 349. What was the object of this experiment?

A. There were two objects. The first was to see an incandescent lamp, the next was to ascertain whether hydrogen gas would be a suitable substance with which to fill the lamp to prevent the consumption of its illuminating part, and at the same time be safe from explosion; the explosive property of hydrocarbon gas, which we used, being the same practically as pure hydrogen when either is mixed with air; we used the hydrocarbon gas; we could not get hydrogen conveniently.

X Q. 350. Aside from the desire to see an incandescent lamp, am I correct in understanding that the sole object of this experiment was to ascertain if an explosion would occur when burning the conductor to incandescence in any atmosphere of hydrogen or hydrocarbon which contained atmospheric air?

A. Yes, in substance; that we wanted to know how carefully, and to what extent the air would have to be driven out by the hydrogen or hydrocarbon gas to prevent, first, the destruction of the carbon by burning, and second, explosion.

X Q. 351. How long did the conductor remain incandescent in the experiment referred to?

A. Not more than ten or fifteen minutes at a time, I should think.

X Q. 352. How many times was the conductor incandescent?

A. I cannot recollect; several times, and the thing was refilled more than once.

X Q. 353. Was the same carbon used each time?

A. No, sir. I think separate splinters of carbon were used.

X Q. 354. And the flask refilled each time new carbon was used?

1149 A. Yes, sir.

X Q. 355. What was the occasion of changing the carbon, or refilling the flask?

A. I think the carbon fell out of the holders.

X Q. 356. What time did you get to the office of Mr. Sawyer, and how long did you remain there on the day in question?

A. I cannot recollect with accuracy, but my impression would be that I got there between 4 and 5 o'clock, and left there between 7 and 8.

X Q. 357. Am I correct in understanding that the experiment to which you have referred was the only experiment performed prior to your going to Centre street?

A. I have no recollection of taking part in any other experiment than that before going to Centre street.

X Q. 358. Did you witness any other, or learn of any other?

A. No, sir; I have no recollection of hearing or seeing any other experiment.

X Q. 359. Did you or Mr. Sawyer hire the room in Centre street? Do you remember what rent was paid, and whether you paid rent from the time you took the room?

A. I do not recollect whether the arrangements were made by Sawyer or myself, or by both, for hiring the room, but think Sawyer looked it up and engaged it. I paid the rent; am under the impression that rent did not commence with the commencement of occupation, but only after some time elapsed. I do not recollect what the rent was.

X Q. 360. What gives you the impression that your rent did not date from the time of occupancy?

A. The fact that at first we had no power, and had no machinery to run by power, and used a dynamo which was in the cellar below us, and which belonged to Arnoux & Hochausen, and over which we had no control, or its running. Also that arrangements
1150 for power and fitting up the room were made by the owner
or his representative after we went there. I think our occupation at first was by favor to us from the owner or his agent or representative to allow us to avail ourselves of the use of the dynamo, and in hopes that we would hire the room which was vacant.

X Q. 361. How soon after you went there did the payment of rent date from?

A. I can fix it with no certainty whatever. It may have been a week or ten days, and I think that most probable. Or it may have been only one or two days, or up to 20 or 22 days.

X Q. 362. Did you take a lease of the premises for any specific period?

A. I do not think we took a lease. We simply paid money and took a receipt for it, or simply paid it without a receipt, making a memoranda of it.

X Q. 363. Did you agree*d* to take the room for any definite time?

A. I cannot recollect, but am under the impression that we paid for it month by month, for so long as we wanted it.

X Q. 364. Do you mean so far as any obligations on your part to the lessor were concerned you could leave at the expiration of a month or two months or any period you saw fit?

A. Yes; and I think the landlord could compel us to leave at the expiration of any time for which we had paid.

X Q. 365. Did you pay your rent by the month, or how?

A. I do not know, but am under the impression we paid oftener, and in advance.

X Q. 366. Is it your impression that if there was any occupancy without the payment of rent it was merely for a few days prior to some well-established rent day?

1151 A. Yes, or to the usual day of payments by tenants in that building, of which there was a large number.

X Q. 367. Have you any receipts or papers, checks or check stubs, or memoranda showing during what period rent was paid, and if so, will you produce them at the next sitting?

A. I do not think I have any, but will look for them, and if I find any produce them.

X Q. 368. What arrangements for power and fitting up the room were made by the owner? Describe in detail what fitting up was done.

A. Some shafting and pulleys were put up, floors mended, windows fixed, doors closed off, work-benches put up, partitions run, some or nearly all of which was done by the owner, and some at our expense.

X Q. 369. Are you quite positive that there were no pulleys and shafting in the room when you first occupied it?

A. No. I am quite positive that there were pulleys and shafting in it, but additional pulleys were put up, and the same or other shafting was taken down, adjusted or rehung, so that we could get power from it.

X Q. 370. Did not arrangements exist in the room prior to your occupancy?

A. I think that the pulleys and shafts that were there were adjusted and in use for power in other parts of the building, and could only be used in this room by disconnecting the power elsewhere in whole or in part.

X Q. 371. If it be the case that you occupied the premises in question for any period without the payment of rent, is it your impression that you occupied them merely so long as it may have taken to make the alterations or repairs referred to?

A. No, sir; but the fact that these things were being done and were necessary before we or anybody else could make use of the premises, together with some dim recollection, makes me
1152 think that the rent did not commence to run for some time after we went there; but as I said before, I am not positive in regard to this.

X Q. 372. When was the experiment in the Coal and Iron Exchange made, and when did you hire the room in 43 Centre street?

A. It is my present recollection that the room in question was hired on the 7th day of March, 1878, but occupied by us on the 6th day of March, 1878, and I believe that the experiments to which I referred as taking place at the Coal and Iron Exchange, took place on the 6th or 7th day of February, 1878. I know it took place prior to the 15th day of February, 1878.

X Q. 373. When did you give up the rooms in Centre street?

A. I forget whether in May or June, 1878. I should have to try and refresh my recollections in regard to it to be certain. This I will endeavor to do.

X Q. 374. Please describe with reference to the room you occupied in Centre street, the basement in which was the machine owned by Arnoux and Hochausen, to which you have referred.

A. As I recollect, our room was on the second floor on the northwest corner of the building. Arnoux & Hochausen's machine was in the basement underneath us, or cellar, I don't know which, with entrance from the court. The wires were run from the machine, on the outside walls of the court, and into a window of our room.

X Q. 375. By what power was the armature of the dynamo driven?

A. By a steam engine.

X Q. 376. Do you mean by a separate steam engine that was placed there for that purpose, or by the ordinary engine in use in the building?

A. I do not think there was a separate engine put in for
1153 the purpose; the armature of the machine, when driven at
all, was connected by a belt, pulleys and shafting driven by
an engine in the building.

X Q. 377. Was this the machine used by you during your stay in Centre street?

A. No, only at first. The first day or two, or three, perhaps.

X Q. 378. What other dynamos, if any, did you have while there?

A. We had two or three of Arnoux & Hochausen make; one built especially for us, and the other, or others, loaned to us by them. A Weston machine or two; some other, possibly a Farmer-Wallace machine, or possibly some other manufacturers'.

X Q. 379. Are you able to state definitely how many, and what machines, you had while at Centre street?

A. No.

X Q. 380. Why are you not able so to state?

A. Because we had a considerable number and variety of machines which we so tried.

X Q. 381. Are there no books, correspondence, papers, or memoranda of any kind, which would show just what machines you had, and where you obtained them?

A. I think not, except an agreement of Mr. William Hayes for the purchase of the one machine of Arnoux & Hochausen, which we bought. The other machines were loaned to us, or sent in on trial.

X Q. 382. Can you state what machines were used by you in Centre street in your experiments, as distinguished from those you merely had on trial?

A. I should think that we principally used Arnoux & Hochausen machines.

X Q. 383. In the months of March, April, May and June, 1878, please state how many makers of dynamos there were from whom machines could have been procured?

A. I don't know.

1154 X Q. 384. You have stated that the Arnoux & Hochausen
machine which you first used was in the basement. Please
state when it was that you first got a dynamo in your room in
Centre street, and from whom you got it.

A. My recollection is that about the time the machine in the basement was taken away, or perhaps before then, we had agreed with Arnoux & Hochausen, or rather Mr. Wm. Hayes had for us agreed with them, to purchase a machine, and that in the meantime, and within a few days after we went to 43 Centre street, they loaned us a machine and kept on supplying us with a machine for most of the time up to the 25th of March, 1878, when the machine bought from them was delivered to us at 43 Centre street.

X Q. 385. What enables you to fix the 25th of March as the date of delivery of the machine to you?

A. I subsequently bought the machine and paid for it, and now have it, and the original bill for the purchase was endorsed over me, and I have it. I now produce this bill.

X Q. 386. Is this the bill of the first machine purchased for you in experiments in Centre street?

A. It is.

The same is offered in the evidence, and it is stipulated between counsel that a fac-simile copy be marked in evidence, and that if either counsel request the original to be produced at the hearing the same will be produced by complainant's counsel, and the same is marked "Defendant's Exhibit Dynamo Bill."

Counsel for complainant objects to the exhibit as not appertaining to anything brought out by the examination-in-chief, and as not pertinent or material to any of the issues of the case, nor as part of a legitimate cross-examination.

Witness adds: I desire to state that this machine may have been delivered prior to the 25th of March, 1878, but was certainly delivered as early as that date.

1155 X Q. 387. What enables you to fix that date as the day of delivery of the machine, or prior to which it was delivered?

A. The bill and my recollection after seeing the bill.

X Q. 388. Have you any memoranda by which you fix this date outside of the bill itself, or is there any circumstance which enables you to fix that date?

A. My recollection is that the machine was to be specially wound; that is was delivered and tried. Mr. Hayes came to see it perhaps immediately, perhaps after some days, and then gave a check to pay for it. I do not know of any other memoranda, and I don't recollect at this moment of any other circumstance.

X Q. 389. What is meant by the words "No. 1," in this bill?

A. I don't know, but suppose it to refer to the character of the machine.

X Q. 390. What is meant by the entry beginning with "May 6th, '78," and ending with "Jacob Hayes," at the bottom of the bill, and is that entry in your handwriting?

A. It means just what it says, and it is in my handwriting except the signature, which was made by, and is in the handwriting of Jacob Hayes.

X Q. 391. How did you come to purchase this machine from Mr. Hayes?

A. Mr. Hayes became one of the stockholders in the organization of the Electr*ic*-Dynamic Light Co., and wanted me to take the machine and pay him for it, and then I think the same money was applied on his subscription for stock.

X Q. 392. Is it your present recollection that the light machine in the basement of the building was removed some two or three days after you went to Centre street?

1156 A. It is; but speaking from recollection after nearly eight years, and the time may have been longer than two or three days or even a week.

X Q. 393. Do you feel quite confident that it was not over a week?

A. I can only say that I think it was not, but it may have been. I am not extremely confident.

X Q. 394. I understand your recollection to be that you went to Centre street, the 6th or 7th of March; that the light machine referred to was in the basement at the time and remained there some two or three days, or possibly a week thereafter, and that the machine mentioned in the exhibit was delivered on the 25th of March? From the time of the removal of the light machine to the delivery of the machine mentioned in the exhibit, what machine, if any, did you have?

A. We borrowed from Arnoux & Hochausen one, two or three machines similar in form to the one we bought of them, but not specially wound for lighting. My recollection is within a day or two after we went into the building, and from that time up to the time when the machine we bought was delivered, and perhaps afterwards. It was one or more of these borrowed machines that we had for use during the period of which you inquire.

X Q. 395. And no other?

A. I don't recollect.

X Q. 396. After receiving the machine mentioned in the exhibit, was any other machine used or tried by you in Centre street?

A. Yes; similar Hochausen machines, also Weston, and I think Farmer & Wallace, but I cannot be certain now, whether the trials of the Weston, and Farmer & Wallace were before the 25th of March, 1878, or after, but I think they were after. We also probably tried another machine, but I don't recollect the maker's name.

X Q. 397. Was any other machine bought by, or for you while in Centre street?

1157 A. I think not. We ordered another and different kind of Arnoux & Hochausen, but I think it was after we left Centre street.

X Q. 398. Can you not state just how many machines you had while in Centre street, either in use or on trial?

A. No, sir.

X Q. 399. Can you state what machines were used in contradistinction to those you tried, but did not use?

A. Yes, mainly we used a large lighting machine which Arnoux & Hochausen had in the basement, the machine referred to in the bill "Defendant's Exhibit Dynamo Bill;" one or more machines similar to the last one mentioned made by Hochausen, but not specially wound; one or more Weston machines, but of these last we made little use.

X Q. 400. Were there machines other than the light machines in the basement placed in your room in Centre street?

A. Yes, sir.

X Q. 401. How were the armatures of these machines driven?

A. By steam power through shafting, pulleys and belting in the room connected by a belt to a pulley in another room.

X Q. 402. Am I correct in understanding that you had no separate engine, but depended on the power in the building, and that the armatures of the machines in your room were belted to pulleys in the building actuated by the steam power in the building?

A. Yes.

X Q. 403. Was any change made in the pulleys and shafting in the room after you went there?

A. Yes, sir.

X Q. 404. Please state what changes were made by you and Mr. Sawyer, or by the direction of either, in the pulleys or shafting?

1158 A. I cannot recollect details, except that we bought one or more pulleys, and I think some shafting and hangers, counter-shaft and apparatus, fast and loose pulleys and belting, and the engineer of the building, I think, put it up, assisted by Mr. Sawyer's father, who was employed by us; possibly part was paid for by the landlord, or may have been furnished by him.

X Q. 405. From whom were the articles mentioned purchased, by whom, and who paid for them?

A. I paid for them. I think they were selected by Mr. Sawyer's father and myself at several machinery places on Centre street and its vicinity.

X Q. 406. Can you not remember, or have you no means of ascertaining, at what places these purchases were made?

A. I cannot now remember, and don't know that I have any means of ascertaining.

X Q. 407. Did you keep any memoranda of expenses incurred by you while in Centre street, or no account of moneys expended?

A. Yes; I kept a memoranda of what I paid out at first as a loan, and after we had an agreement, I think March 19th, or thereabouts, as applying upon our agreement.

X Q. 408. Do you mean that you kept an account of moneys expended by you, showing when, for what, and to whom such moneys were paid?

A. I think not generally, but only of the dates, amounts and what they were for.

X Q. 409. Would the purchase of the things referred to appear in such accounts?

A. The amounts paid by me for things would appear, I think, and I think that the things purchased, but not unfrequently these memorandums would be made by Mr. Sawyer, by my telling him what the things cost.

X Q. 410. How were the accounts kept, in a book?

A. No. No regular accounts were kept. I had a little pass book in which I was in the habit of entering the amounts

1159 paid out, including money given to Mr. Sawyer, but many of the entries in this book covered one entry as expenditure on account of electric lighting, what I paid out for things, and money given to Mr. Sawyer. The object of the book was for my own information, in order that I might keep within the limit of the amount of money which I was to advance under my agreement with Mr. Sawyer.

X Q. 411. What has become of that little book?

A. I don't know.

X Q. 412. When did you last see it?

A. It was used in the Edison interference case, and an extract from it appears in my testimony in that case, and I do not recollect to have seen the book since, and it was then in the hands of Mr. Amos Broadnax, counsel.

X Q. 413. Were the shafting and pulleys mentioned by you put up, and if so, how long did it take to place them in position?

A. Yes, they were put up. I cannot recollect, not long, probably.

X Q. 414. About how long?

A. It was only a small amount of work and may have taken not more than a day or so.

X Q. 415. Please state as nearly as you now recollect, what were the shafting and pulleys and hangers in the room in Centre street when you went there, and what changes in them and additions to them did you make while there?

A. I will give the best of my recollections, but cannot assume them to be accurate. There were one or more shafts in the room driven by the power in the building, on which were several pulleys of different sizes. We put onto one of these shafts an iron pulley of larger diameter than in the room. We also put up one or more pieces of shafting, supported by hangers parallel to the shafting that was in the room and having iron pulleys on it or them, some of
1160 which were fast and others loose; belting between the pulleys on the shaft and means of shifting from fast to loose pulleys, and reverse; belting from the pulleys of the shafts that we put up to the dynamos that we used. I think this was all that might be called machinery that we put up. It seems to me that we had a lathe or lathes which we had in motion by this machinery, but I am not certain.

X Q. 416. What was the object of altering the pulleys and shafting, or adding to those as described in your answer?

A. To give proper speed to dynamos, to enable us to place them where we wanted them in the room, and to start and stop them without interfering with any other machinery in the building.

X Q. 417. Please state how much the alterations and additions made by you diminished or increased the speed you were able to attain.

A. I cannot.

X Q. 418. Can you not approximately?

A. No, sir.

X Q. 419. In making the alteration or additions referred to, were they made with reference to increasing or diminishing the speed which you could obtain directly from the pulleys and main shaft, when you went there?

A. I think they were made partly for obtaining increased speed in the movement of dynamo over what could be obtained by belting directly from the pulleys that were there when we went there, and partly to enable us to control the power and stop and start when we wanted to.

X Q. 420. Who was the engineer that you have mentioned that may have assisted Mr. Sawyer in making these alterations?

A. I do not know as I ever knew his name.

X Q. 421. Was he the engineer of the building, or a person whom you regarded as such?

A. I think he was.

1161 X Q. 422. What machinery, if any, other than pulleys and shafting and hangers referred to did you have in the room in Centre street? By machinery I do not include apparatus.

A. Dynamo machines, I think a lathe or two, and we may have other things, but I do not recollect.

X Q. 423. What makes you now think that you had a lathe or two, when but a few moments ago you could not remember whether you had or not?

A. I meant to express myself both times as in doubt, but at the same time to have expressed a possibility that we may have had them. I have no distinct recollection on the subject.

X Q. 424. Do you recollect any machinery other than lathes which you think you may have had at Centre street?

A. I don't know.

X Q. 425. Please state what tools you had at Centre street.

A. We had a pretty good assortment of drills, files, chisels, dies, screw-taps, hammers, saws, wrenches and other bench tools, with vices, laps, and I cannot recollect what all, also glass-cutters and glass-grinders, grindstones, whetstones, bits, bit-stocks. I cannot recollect all.

X Q. 426. Where did you purchase or get the tools referred to in your last answer?

A. I do not recollect.

X Q. 427. Do you recollect whether they were, in fact purchased?

A. I think some of them were and some of them were not.

X Q. 428. From whom were those that were purchased obtained, or who did the purchasing, and who paid the bills?

A. Can't recollect, except some things from Mr. Frasse, then in Chatham street. He is a well-known toolman. I ultimately paid for everything.

1162 X Q. 429. You have enumerated the machinery and tools which you had at Centre street. Please state what apparatus you had there.

A. We had a very great variety of apparatus, retorts, gas-holders, gas bags, tubes and tubing in glass and metal, stop-cocks, oil and alcohol, and kerosene lamps, gas-heating apparatus, gas-generating apparatus, electrical apparatus, photometer, air pumps, one or more hand metallic, and one or more mercurial exhausting apparatus, operated on the principle of Geissler's pump. I do not know what else, but a great variety of things, among which was a great variety of utensils or apparatus in glass, glass mould, boxes for carbonizing, means of drying gases, deoxidizing gases and purifying gases.

X Q. 430. Define what you described as a gas-heating and gas-generating apparatus.

A. Heating apparatus, operated instead of lamps by burning gas, and apparatus heated up by lamps or burning gas through which gases to be heated were passed. Charcoal furnaces, urged by bellows for heating apparatus. We had several of these heaters of different forms and kinds. Of the gas-generators, I remember we had several for producing hydrogen gas, several for producing nitrogen gas, several for producing carbonic-acid gas, some for producing chlorine and several for producing cyanogen.

X Q. 431. Please to describe the "charcoal furnace" referred to in your last answer.

A. One kind was an ordinary furnace like a tinner's or roofer's furnace; another one like an ordinary household charcoal furnace; another one made long and divided into compartments, on which was supported tubing running lengthwise of the furnace to prevent the tubing from bending when highly heated, similar to like apparatus as sold by chemical-apparatus dealers, but longer and larger; some others of the same kind but of less size. In enumerating these things I desire to be understood as mentioning those 1163 things which come to my mind without attempting to give an exhaustive list, which I do not think it would be possible for me, or anybody else to do, after this length of time, nearly eight years.

X Q. 432. Please to describe what you refer to as a household furnace.

A. It is known as a pail furnace, and can be bought in every establishment for the sale of household articles, used to boil a tea-kettle or heat a flat-iron, or the like, open at the top with a grate inside, an air space under the grate made sometimes of earthware, and sometimes of sheet or cast iron.

X Q. 433. Please state the dimensions and material of the furnace on which tubing was supported.

A. Some eight or ten inches square in cross-section, and from two to four feet long, made of sheet iron with a grate and ash plate under the grate, lined with fire-brick, and with fire-brick or iron partition for supporting the tubing which ran lengthwise of the furnace. In cross-section this fire-box inside, after the bricks were in, would be from three to six inches square; the grate extended the whole length of the furnace, and fire could be built in any compartment, or in all of them; it was fitted with a perforated cover to put on or take off as we chose.

X Q. 434. Please to specify what electrical apparatus you had while in Centre street.

A. We had several galvanic batteries; some standard resistances, galvanometers, electric lamps, dynamos, thermo-electric battery, ordinary electroscopes. I do not recollect anything else at present; we had electro-magnets and electric coils, switches and cut-outs, regulator, two or three devices; I don't know what else.

X Q. 435. The electric lamps, switches, cut-outs and regulators

1164 mentioned in your last answer were not apparatus which you bought, or took to Centre street for the purpose of making experiments, but were made there by you in the course of your experiments. Am I correct?

A. Yes.

X Q. 436. Have you now enumerated all the apparatus which you now remember you had in Centre street, and are you quite sure that all things enumerated by you were had by you and Mr. Sawyer while in Centre street?

A. I am quite sure that all the things enumerated by me were had by Mr. Sawyer and myself while in Centre street; I have not enumerated all, or nearly all of them, but only such as comes to my recollection while testifying; of these I have enumerated all that seem to me important to mention, which come to my mind.

X Q. 437. From whom was the various apparatus you have mentioned procured?

A. I cannot recollect.

X Q. 438. Cannot you recollect where any of it was procured?

A. Yes; some of it I got from different glass factories over in Brooklyn; some from Mr. Hahn, a glass-blower in William street, on North William street, near Chatham; some of it was bought from Hagerty Bros., in Platt street; some of it was bought from different rubber stores; some of it from different tin and sheet-iron workers; I think one of these was John Borkel, in Elm street; some of it was bought from an apparatus store in Barclay street; I cannot recollect the name; there was a glass-worker in Chambers street that fixed some apparatus for us; I don't know his name; some of it was got from an apparatus store in Greenwich street; I don't know the name or location; a good deal of it we made ourselves, at 43 Centre street; a good deal I took from my own private apparatus at my house; some was made and fitted up by William Sharp, who was in what was then known as Hickory street, Brooklyn; some we borrowed from different people; the dynamos I have spoken of, some electrical apparatus was obtained from Mr. Chester; 1165 some from Mr. Benjamin; I am not quite certain, but think some was borrowed from the School of Mines.

X Q. 439. In the aggregate as near as you now remember, what did this apparatus cost?

A. I cannot recollect, but think probably from $2,500 to $4,000.

X Q. 440. Who provided the money?

A. I and my friends provided it.

X Q. 441. Did your friends intrust their money to you, and did you pay for the apparatus, or did you pay for some and they for others?

A. I cannot recollect whether the money all passed through my hands or not; my impression is that it did not.

X Q. 442. Is it then your impression that some of your friends purchased apparatus directly, which apparatus was used by you in Centre street?

A. No, sir; but that they furnished money to Mr. Sawyer, who purchased apparatus with it.

X Q. 443. Were any books, accounts or vouchers ever kept of the expenditure of this money?

A. I have already stated that there were not; but memorandum accounts were kept by Mr. Sawyer, handed to me from time to time, and I think that said memorandums were all handed to Mr. Broadnax in '79. I also had a little book there, that had an account of expenditures, of which I have before spoken of in this case.

X Q. 444. Was any of this $2,500 or $4,000 expended for apparatus, paid by check, and if so, by whose?

A. I don't know that any of it was; I never paid any by check, except checks to the order of Mr. Wm. E. Sawyer, which he usually immediately endorsed, and which I therefore either gave him money for, or sent to the bank and got money so that he could have cash to make payments, unless it be in the case of a dynamo machine from Hochausen, about which I have testified.

1166 X Q. 445. You say that the apparatus bought cost from $2,500 to $4,000. How much, about, was expended for experiments while you were in Centre street, including rent, labor and everything and exclusive of payments to Mr. Sawyer for his personal services or use?

A. I think my estimate of apparatus includes experiments; it was all experimental till near the last apparatus and all; but does not include wages for Mr. Sawyer's personal expenditures, and is but a guess. I have no means of verifying it that I know of at present.

X Q. 446. And of these expenditures you know of no letters, vouchers, or memoranda of any kind, which would show in detail for what and when they were made excepting the memoranda and book of which you have testified? Is this correct?

A. I do not, unless among the papers which I gave to Mr. Broadnax, there may have been, as I testified, receipts of tradesmen, and it seems to me that there were such papers, but they may have been all kept by Mr. Sawyer.

X Q. 447. Where did you get the hand metallic air pump or pumps mentioned?

A. Mr. Sawyer borrowed it from somebody.

X Q. 448. Did you have more than one?

A. I am not certain whether he had more than one, or the same one at several times.

X Q. 449. Do you know from whom it was borrowed?

A. I do not recollect from whom it was borrowed.

X Q. 450. Did you purchase any hand metallic air pump or own one when in Centre street?

A. No, sir.

X Q. 451. Did you have one there continually, or did you borrow it at such times as you wanted to use it?

A. We only borrowed it, though I think it remained several days at a time, and only used it until we got the mercury exhaust rigged up.

1167 X Q. 452. From whom did you get the one or more mercurial exhausting apparatus operated on the princip*al* of Geissler's pump mentioned in your last answer?

A. We got the stop-cocks from Mr. Hahn in North William street, and some of the glass tubing; the rest of glass tubing, glass bulbs and tubular bottles I got made in a glass factory in Williamsburgh, and we rigged up the apparatus ourselves. We got 60-odd pounds of mercury through Mr. Haggerty, of Platt street.

X Q. 453. Were accounts kept with any of these people so that their books would show their dealings with you, or were all payments made in cash as the bills were incurred?

A. We kept no accounts with anybody, and paid cash for everything as we bought it.

X Q. 454. What was your working force at Centre street?

A. William E. Sawyer and myself; Mr. Wm. Sawyer, his father, part of the time; Mr. Sharp there part of the time, and part of the time at his shop in Brooklyn. A Mr. Keating and his men, one or two of them part of the time only at his shop in New York. Geo. Sawyer, a boy who ran errands.

X Q. 455. Were Sharp and Keating employed by you in Centre street?

A. Sharp was, but Keating, who had a shop of his own, was not, unless temporarily.

X Q. 456. Where are Sharp and Keating now?

A. Mr. Sharp works for Wallace. Mr. Keating I suppose to be dead. I have searched for him, and been unable to find him for some years past.

X Q. 457. I understand that you left Centre street the latter part of May or the 1st of June. What was the occasion of your leaving?

A. The occasion of our leaving Centre street was that we had got our lamp and other inventions perfected and did not desire 1168 to go further until we secured our patents, and desired to avoid expense, while we did not need a workshop or laboratory.

X Q. 458. Do you mean that your inventions were perfected, and that you were now ready to manufacture them?

A. Yes; many of them.

X Q. 459. Am I correct in understanding that you devoted your energies to securing patents on your inventions, and did not care to do any more work until they had been secured?

A. Yes; that and organization and planning, and did not care to do any other work requiring the use of a laboratory or workshop just then.

X Q. 460. What were your habits in regard to going to the laboratory in Centre street?

A. I was there from early morning until 9 or 9.30, an hour or more at noon, and from 3.30 until dark. Frequently at other times in the day. This was my habit, and about the only exception was, when I was away hunting up things for use in the shop.

X Q. 461. How early in the morning would you get there?

A. I was usually there for about an hour—sometimes more—about 8 o'clock.

X Q. 462. During all this time were you attending to your professional business?

Yes, sir.

X Q. 463. Was not your professional business at this time a large one, and did it not involve the custody and management of large interests?

A. Yes, sir.

X Q. 464. What were Mr. William E. Sawyer's habits?

A. So far as the attendance of the laboratory was concerned he was in the habit of being there all day.

1169 X Q. 465. Was he addicted to intemperance at this time?

A. I never saw him the worse for liquor while we were at Centre street.

X Q. 466. What were Mr. William Sawyer's habits as to attendance at the laboratory?

A. He was there during the usual work hours of mechanics, except when working at some other shop for us.

X Q. 467. Please answer the same question with reference to Messrs. Sharp and Keating?

A. They were working mostly at their own shops.

X Q. 468. Did you neglect your other business to attend to experiments at Centre street, or were you attending to it regularly?

A. I was attending to my other business regularly during my ordinary office hours, except when I went out at noon, which I was not in the habit of doing. My ordinary business hours were from 9 to 3.30.

X Q. 469. Was Sawyer and his father in the habit of getting to the laboratory as early as 8 o'clock in the morning?

A. Yes; they were usually there when I got there, except when the father was going elsewhere.

X Q. 470. To get to the laboratory at 8 you would have to leave your house at 7, would you not? Was it your habit of leaving at that hour?

A. Yes, sir; from 7 to a quarter past; and the time from my house to 43 Centre street, was usually about 50 minutes.

X Q. 471. Do you think you were there every day during the time the laboratory was there?

A. I think I was, but may not have been during the first few days of April, as those days were very busy days at my office; nor during the first few days of May, for a like reason. I have no positive recollection except as to general habit.

1170 X Q. 472. Was Mr. William E. Sawyer there every day?

A. I think he was at the place every day—some part of every day—except during the latter part of the period, when we were there; he was, however, frequently at my office during the time that I was at leisure to give attention to the matters we were at work on.

X Q. 473. Then in point of fact, William E. Sawyer was not there every day, and all day?

A. Well, those words would give a correct impression of his attendance at the place 43 Centre street, his absences being exceptional occurrences made mostly for my convenience.

X Q. 474. Was he dissipated at this period?

A. At this time I had no knowledge of Mr. Sawyer's being an intemperate man or a*b*dicted to drink or other excesses; but from events which subsequently came to my knowledge, I had reason to think and believe afterwards, that he had been and was a dissipated man at this time, but under much self-restraint.

X Q. 475. Was not his father also a dissipated man and addicted to drink at this period?

A. My reply is the same as to the last question.

X Q. 476. In the Sawyer-Man-Edison interference the following question was asked and answer made by Mr. Sawyer: State as near as you can recollect, about how long you and Mr. Man continued your experiments at 43 Centre street.

A. I thould think about two months, all the time we were there.

X Q. 477. Does your recollection agree with Mr. Sawyer's as to this?

A. Yes, substantially; it may, however, — been longer than two months, and my impressions are that it was, but without refreshing my recollection I cannot speak with accuracy.

1171 X Q. 478. In the same interference, the following question was asked Mr. Sawyer, and answer made by him:

"After you got through there did you resume your experiments at any other place? A. We moved from there to No. 2 Howard street, where I don't think we made any experiments on lamps, not having any facilities for such experiments; we then moved in the fall of the year to 94 Walker street; I have got memoranda to show of these things; we moved to 94 Walker street during the 18th and 19th of October, 1878."

X Q. 479. Do you agree with Mr. Sawyer as to his statement in the answer quoted, and is it a fact that you moved to Walker street about the 18th or 19th of October, 1878?

A. I do not; my recollection is different, and I think that the word "October" is a mistake, and should be September; but I speak from recollection, and there are papers which will show the date when we went to Walker street. As to the work done while we were at the corner of Howard and Centre streets, my recollection does not agree with Mr. Sawyer's. We made a lot of experiments at the corner of Howard and Centre streets, and had as assistants Mr. Frank Holbrook and Mr. Edward Myers; we also had Messrs. Arnoux & Hochausen, who were above us, doing a lot of work for us.

X Q. 480. I now call your attention to the following part of your answer to the 17th question submitted to you in the same interference, and given in March, 1881: "I had been speaking thus far of only what took place up to the 1st of June or last of May, 1878. We had no convenience for working from that time up to September, and our experiments were renewed in September and continued on until late in March, 1879." Is it true, as there stated by you, that you had no convenience for working from the last of May, 1878, and that your experiments were only renewed in September?

1172 A. It is true that from the time we left Centre street until we went to work at the corner of Howard and Centre streets we had no shop, and that our experimental work as experiments was discontinued; during this period, however, we were engaged in the discussion of plans, designs, calculations, etc., and in ordering material and in getting apparatus for manufacture, and in getting manufacturing done, though not as actively as after we went to work at the corner of Howard and Centre streets; this period was from the last of May or 1st of June until the last of August or 1st of September; but we were not engaged in experimental work, though upon reflection and refreshing my recollection, our room at Howard and Centre streets was hired perhaps as early as July. Mr. Sawyer went on his summer vacation, and afterwards I went on my vacation, and we did not resume experimental work until my return, about the 1st of September.

X Q. 481. As I understand you, you did no experimental work from the time of leaving 43 Centre street until September 1st, 1878. Is this correct?

A. That is my recollection—that is to say, I do not recollect anything we did during this period.

X Q. 482. Where was it that experimental work was resumed?

A. At No. 2 Howard street.

X Q. 483. How long after September 1st were you at Howard street?

A. My recollection is until the last part of September; I can fix the date exactly, I think.

X Q. 484. How many rooms did you have at Howard street, and what were their sizes?

A. Only one; about 12 x 20, with shop facilities in another room about 25 x 40 or 50, occupied mainly by Arnoux & Hochausen.

X Q. 485. What tools, apparatus, or machinery did you have in this Howard-street room?

1173 A. The same that we had in Centre street, or part of it; part, I think, being left in 43 Centre street until we wanted to use it.

X Q. 486. Between the time of leaving Centre street and going to Walker where were the tools, apparatus and machinery referred to, kept?

A. I think they were stored at 43 Centre street, except dynamo, lamps, switches, and apparatus of delicate character. The dynamo was taken and set up at the corner of Centre and Howard streets, opposite No. 2 Howard street; the other things at my office No. 3 Mercer street.

X Q. 487. With whom were the things stored that were left at 43 Centre street?

A. I think they were left in the room that we occupied; packed up in one corner that was partitioned off for the purpose.

X Q. 488. What power did you have at Howard street?

A. We had only the steam power in the building, which was also used for several buildings in the neighborhood.

X Q. 489. Did you have pulleys and shafting in that room?

A. No, sir; they were all in the room above occupied by Arnoux & Hochausen.

X Q. 490. How did you get the current that you used there?

A. From dynamos in a room of Arnoux & Hochausen, our own and different ones belonging to them, from which wires were led to an office room of Arnoux & Hochausen, and from thence directly to our room underneath. Lamps were set up part of the time in Arnoux & Hochausen's room, but mostly in our room underneath; the regulators, resistances, switches, and measuring instruments, etc., were all in our room; we had no dynamo in our room.

1174 X Q. 491. How were the dynamo machines from which you obtained your current, driven?

A. By pulleys and shafting in the building; we did not put up any pulleys and shafting; we may have changed it around to get the velocity we wanted, and connect it to our counter-shaft with fast and loose pulleys.

X Q. 492. Which of the dynamos that you had at Centre street did you use in Howard street?

A. The one that was bought of Arnoux & Hochausen, and one or more that we borrowed from them.

X Q. 493. Then none but Arnoux & Hochausen machines were used, as I understand it?

A. I don't recollect any but Arnoux & Hochausen machines were used; I suppose that all these machines would be more properly designated Hochausen machines, as they were devised by him; built as I understand by Arnoux & Hochausen.

X Q. 494. With the exception of the machine mentioned in the bill you have produced were these machines the type of machine at that time manufactured by Arnoux & Hochausen?

A. Yes, for electroplating mostly, excepting the one which they wound especially for our use.

X Q. 495. Was the one they wound specially, the one referred to in the exhibit?

A. It was not the one referred to in the exhibit, but another machine, and was by them delivered to us; but Arnoux & Hochausen desired to sell us a machine and to experiment in machines for incandescent lighting, and so wound one or more machines for our use; they had no incandescent lights and we had; it was, therefore, a matter of mutual advantage.

X Q. 496. Which was it, one or more machines that was wound as you have described in your answer?

A. I think one for our special accommodation?

1175 X Q. 497. Was this winding done at their suggestion or according to their ideas, or at your suggestion and according to your ideas?

A. According to the joint ideas of Mr. Sawyer and Mr. Hochausen. I do not think I had anything to do with it except to ask or suggest its being done.

X Q. 498. Am I correct in understanding that this machine was made while you were at Howard street?

A. It was wound while we were there.

X Q. 499. Was it ever used by you, and if so where?

A. It was used by us, while we were at the place, No. 2 Howard street, for a short time; it was then resold by Arnoux & Hochausen, as I understood it, for electroplating business.

X Q. 500. Am I correct in understanding that with the exception of the machine referred to in the exhibit, and the one last mentioned, the only machines used by you in Howard street were the electroplating machines at that time sold by Arnoux & Hochausen?

A. Yes.

Witness states that having obtained from Mr. Broadnax an account made by the witness against the Electro-Dynamic Light Company, which includes the rent paid for the premises at Nos. 2 and 4 Howard street, and shows that the occupation of those premises commenced on or about June 20th, 1878, and that the last payment of rent was on September 27th, 1878. That he also obtained from Mr. Broadnax the lease of 94 Walker street to the said company, which is dated Oct. 15th, 1878; that deponent's recollection of the date of going to Walker street is confirmed by these papers, and by the fact that we moved directly from the Howard-street place to the Walker-street place, and that it was some time after going there before the lease was executed. This same account also confirms my recollection that a large amount of work was done at Howard street, and contains items paid for that work, notably for glass
1176 moulds to Homer Brooks, for glass globes to P. Schneider &
Sons, Archer & Pancoast, for fixtures, Arnoux & Hochausen, for work, other items for material; payments to Mr. Sawyer for expenses incurred by him, etc.

I have also found an entry in my check book, dated April 6th, 1878: "1878, April 6th, Charles "P. Fizer & Co., quicksilver, 81 Maiden lane, "electric light, $27.25;" so that I know *we that* bought quicksilver of P. Fizer & Co., and that I paid for it with my check on April 6th, 1878.

X Q. 501. I understand you to say that you left Howard street the latter part of September or first part of October. Now, what was the nature of the experiments, if any, that were made by you from the 1st of September to the time of leaving Howard street?

A. Experiments in the making of carbons, preparation and treatment of carbons after their manufacture; in making and purifying nitrogen and other gases; experiments in resistances and switches; experiments in dividing the current and in distribution and measurement; experiments in filling the lamps and treating the carbon in process of filling; experiments in exhausting lamps and lamps not exhausted; experiments in safety devices and cut-outs; experiments on globes of different sizes and forms, and generally getting ready to manufacture electric lamps upon a commercial scale and put them in use.

X Q. 502. Was the work done from the 1st of September to the period of your leaving Howard street rather in the nature of getting ready to exploit and produce commercially the inventions which had been perfected, or to make experiments with the view of making inventions?

A. Our object was to get our invention into shape for commercial use, and perfect plans and means of manufacturing, and also we were compelled to continually devise and invent new things.

X Q. 503. Did you consider that you had obtained a lamp which was practical and could be introduced commercially?

1177 A. We did.

X Q. 504. Who composed the force at the Howard-street shops while experiments were going on?

A. I do not think we had any workmen there except Mr. Sawyer's father and Mr. Sharp. We had a large amount of work done outside by the firm of H. L. Judd & Co., Arnoux & Hochausen, by Miller and Newman and by various other people. Mr. George Sawyer was a kind of general utility boy; Mr. William E. Sawyer, Mr. Frank Holbrook, and Mr. E. L. Myers, with some assistance rendered by myself.

X Q. 505. What were the habits of these various people that you have named, as far as attendance at the shop was concerned during the period of September, 1878?

A. Mr. William E. Sawyer was supposed to be at the place all day, also George Sawyer. Holbrook was there, or at a place down in Broadway, near the Battery, for a fortnight, as near as I can recollect, with occasional visits to the School of Mines of half a day or so. Mr. E. L. Myers was there after Mr. Holbrook went away, or in the place down toward the Battery, or at Stevens institute. I do not recollect how much Mr. Sawyer's father was at the place. Sharp was there only a day or two, as I recollect, and did most of his work at his shop near my house in Brooklyn. I was in the habit of going to the place every day, whenever I could find time to do so.

X Q. 506. Was Mr. William E. Sawyer at the place all day, and every day during the month of September?

A. I cannot state at this length of time whether Mr. Sawyer was there every day and all day, or not. I can only say that from the time that he returned from his vacation, and we got to work there in the latter part of August or first part of September, until we went to Walker street, he was very attentive to work, and worked very hard, and I have no recollection of his being absent from his
1178 duties, which were to be there and to be engaged in the work of the company.

X Q. 507. What were Holbrook's habits as to attendance there? also, Mr. Myers' and your own?

A. Holbrook's habits as to attendance depended whether his work was there or elsewhere. He came about 9 a. m.; was engaged upon chemical work and experiments for the company. For lack of apparatus and convenience, he sometimes went to work at the laboratory of the School of Mines, of which he was a graduate, and sometimes went down to the place near the Battery. He was industrious, and usually worked until dark. Myers' employment was similar to that of Holbrook's, with the addition of doing some electrical work and measurements. He was in the habit of getting in about 9.30 a. m. and leaving at 4.30. He worked at Howard street, at the place down Broadway, or at the Stevens institute, of which he was a graduate. I was at the place sometimes in the morning, on my way to my office, for a few moments; sometimes at noon, sometimes at night, sometimes morning, noon and night, after business hours. My attendance there was very irregular, and sometimes, instead of going there, I sent for Mr. Sawyer to come and see me.

X Q. 508. What was the apparatus to which you refer which made it necessary for Mr. Holbrook to go to the School of Mines?

A. Chemical apparatus, such as pumps, tubing, glass holders, retorts, stop-cocks.

X Q. 509. What kind of pumps do you mean?

A. Air pumps.

X Q. 510. Did you not have apparatus of the character mentioned at the Howard-street shop?

A. Yes, I think so; but both Holbrook and Myers thought that the apparatus at the colleges were better and more convenient than we had, and thought they could do better work there, espe-
1179 cially such work as they might desire for subsequent experi-
mental tests. Our lamps were made to be put up and taken apart, sealed and unsealed. We were in the habit of filling them and of running them lighted, both lamps filled with nitrogen gas of ordinary atmospheric pressure, and also after filling with gas and exhausting to a different degree of exhaustion, and also when exhausted not having been filled. We tested them while running, while lighted, and being run; by throwing a picture of the lighted carbon on a screen and watching the effect of the atmosphere of the lamp on the carbon, and after the lamp had been run for awhile, we tested the atmosphere of the lamp chemically, to ascertain what change had taken place in the atmosphere of the lamp or carbon burner or both; and it was with reference to those delicate tests that these gentlemen went to their various colleges.

X Q. 511. What was the rent of the room in Howard street?

A. Ten dollars per month.

X Q. 512. What was the reason for leaving the Howard-street shop?

A. Want of room and facilities for doing work.

X Q. 513. Please state the size of the laboratory at Walker street and Elm, and who composed the working force there.

A. One loft about 20 by 50 or 60, the same working force as Howard street, except that Mr. Holbrook only worked, if at all, for a few days there. The elder Mr. Sawyer, E. L. Myers and Mr. Sharp were there all the time. Machinists and workmen and instrument-makers were hired from time to time, and Mr. Lawrence Myers was there about a month.

X Q. 514. What was your habits as to attendance there?

A. I was more attentive during the month of October than at

Howard street, spent a good deal of time there, and did some
1180 work, chemical and testing myself. Afterwards Mr. Lawrence Myers came to relieve me of the necessity of being at the shop so much.

X Q. 515. What tools, machinery and apparatus did you have at the Walker-street laboratory?

A. We had a very complete set of machinist's and instrument-maker's tools, a partial set of carpenter's tools, a miscellaneous lot of bench tools of all kinds for doing all sorts of things—working in wood, metals, stone and carbon. A pretty complete chemical laboratory, with pumps, retorts, furnaces, piping, tubing, stop-cocks, pinch-cocks, and other chemical apparatus; two dynamos, two engine lathes, lathe tools and gearing, steam engine, pulleys, shafting and belting, electrical instruments, photometers, electrical testing and measuring apparatus, lamps, switches, resistances, electroplating baths and apparatus, electric batteries, lenzes, etc., etc.

X Q. 516. I understand that the Walker-street laboratory was given up in March, '79, and that the experiments of Sawyer and Man at that period ceased? Am I correct?

A. Yes, sir.

X Q. 517. What was the nature of the experiments conducted at Walker street, speaking generally?

A. They were for the purpose of perfecting and exhibiting a system of incandescent lighting with all its necessary accessories, and getting it ready to introduce in practical operation.

X Q. 518. What were the dynamo machines used by you in Walker street?

A. One that we bought while in Centre street; mentioned in Defendant's Exhibit No. 1, dynamo bill; one or two machines which we borrowed of Arnoux & Hochausen for trial, of their largest size of lighting machines, and one large machine which we bought of them in September, which was specially wound for us.

X Q. 519. The one or two lighting machines which you
1181 speak of having borrowed for trial, were they actually used by you, and if so, for what period and how long a period?

A. They were used by us while we were there; my impression is from about the middle of October, but for how long I cannot recollect. It seems to me, however, that one of them was there in March, 1879, at about the time that we left.

X Q. 520. What do you mean by saying these machines were on trial?

A. I mean just what I say, that they were on trial for the purpose of incandescent lighting, and to see what their efficiency were for that purpose. You will remember that at this period dynamo machines were not made ordinarily for incandescent lighting.

X Q. 521. Were these machines after being tried regarded by you as efficient for incandescent lighting?

A. None of them except the one that was specially wound for us; the one ordered in September, that was a good machine; the others would light a few lamps, but their electro-motive force was too high and the quantity too low.

X Q. 522. Is it then the fact that the lighting machines to which you have referred after being tried by you, were found not to be adapted to your lamps, and other machines were used?

A. We could use them, but they were not specially adapted to our lamps—not so well adapted as the machine made in September, and the one mentioned in the Exhibit "Dynamo Bill."

X Q. 523. Who ordered the machine of Arnoux & Hochausen in September?

A. I did; as president of the Electro Dynamic Light Company.

X Q. 524. You speak of having an engine. Whose make was it, and when was it bought?

A. It was known as a Hampton steam engine; was bought
1182 from a firm in Liberty or Dey street about the time we went
to Walker street. It was a six-horse-power engine and was run by Wm. Sawyer, Mr. Sharp and George Sawyer also, who got a licence while we were there.

X Q. 525. After the formation of the Electro-Dynamic Light Company on July 11th, 1878, was such experiments as were conducted and such apparatus as were purchased at the expense of that company?

A. Yes, sir; I think so for the most part.

X Q. 526. Did that company keep books of account?

A. Yes, sir.

X Q. 527. Where are the various books of account, minute book, and records of that company, and in whose possession?

A. I don't know; they were in the possession of Mr. Amos Broadnax, counsel.

X Q. 528. Have you any connection with that company at the present time?

A. I am a stockholder and director.

X Q. 529. Do you know who is president, secretary, and treasurer of that company?

A. Mr. Thomas Wallace is president, Jacob Hayes is treasurer, Lawrence Myers is secretary, I think, but I don't know.

X Q. 530. Will you produce the books of account containing the minutes of the board of trustees of that company, or endeavor to cause their production?

A. They are not in my possession, nor under my control, and I don't know where they are, and am not able to produce them.

X Q. 531. Could you not ascertain where they are?

A. I don't know whether I could, or could not.

X Q. 532. Will you endeavor to ascertain in whose possession the books are, and give the results of your efforts?

A. Not unless I am instructed by counsel or the court that
1183 I am under obligations to go and hunt these things up and
try to find where they are, or try to get possession of them, when I have no right to such possession.

X Q. 533. Are not your relations to that company and its successors, its counsel, and the counsel of its successors, its officers and various directors, such that you could, without any difficulty ascertain the whereabouts of such books?

A. Not, except as a personal favor to myself, which I do not wish to ask for, and not then, even as a personal favor, without consent of complainant or its counsel.

Counsel for defendants state- that he desires the fullest investigations made into the inventions and experiments of Sawyer & Man, and for that purpose desires to inspect the books referred to, and therefore requests complainant's counsel to produce, at the earliest possible time, all the account books, minute books, vouchers, bills, letters and other papers, relating to such experiments and inventions during the existence of the company referred to, and kept by, or in possession, or under the control of the Electro-Dynamic Light Co.

Counsel for complainant responds that thus far the so-called cross-examination has been a mere fishing excursion on the part of defendant's counsel, in the hope of finding something that will aid defendant in making a case; that none of the questions and answers given to and made by the witness, have any pertinency, relevancy or competency upon any of the issues in this case, nor upon anything brought out by the examination-in-chief, and that he does not mean to produce any books or papers which have no pertinency or relevancy upon the issues of this case, merely to gratify the curiosity of the defendant, or its counsel, and shall not produce any books or papers unless ordered to do so by the court, which in his judgment are not material to some of the issues raised by the pleadings in this case; that he has as earnest a desire for the fullest investigation of all the facts pertaining to the issues of the case as defendant's counsel, but objects to putting in the record a
1184 mass of irrelevant matter, which can have no other effect than to confuse, perplex and mislead the court.

Defendant's counsel requests counsel for complainant to state in whose possession the books of account and the minute books of the directors or trustees of the Electro Dynamic Light Company are.

Complainant's counsel declines to gratify defendant's counsel's curiosity, but adds that if defendant's counsel can show that any of the books of the Electro Dynamic Light Co., and over which complainant's counsel has any control, possesses any evidence material to defendant upon any issue in this controversy, he will do all that he can to cause their production, or to produce them himself.

Defendant's counsel replies that he cannot tell whether the books contain any such evidence until he has had an opportunity to examine them, and he desires to examine them to ascertain such fact.

Defendant's counsel offers in evidence an account produced by witness, and also a lease from Elizabeth C. Jay to the Electro Dynamic Light Co., and it is agreed that copies may be substituted for the original: the same are marked "Defendant's Exhibit Accounts and Jay Lease."

X Q. 534. I now hold in my hand which purports to be a copy of an agreement made between yourself and William E. Sawyer, dated

March 19, 1878. Please look at the paper to which I refer, and state whether the Electro Dynamic Light Co. was such a joint stock company as was contemplated in the agreement referred to.

A. The Electro Dynamic Light Co. was formed pursuant to an agreement and understanding between Mr. Sawyer and myself, up to the time of its organization.

X Q. 535. On March 19th, 1878, had any joint inventions been made by Sawyer and Man?

1185 A. Yes, sir; but up to that time I don't think that either Mr. Sawyer or myself had considered for a moment whether these inventions were joint or several.

X Q. 536. Did you not at that time, March 19th, 1878, consider such inventions, as had been made in subjects in which Mr. Sawyer had been conducting experiments, either alone or assisted by you, as the sole invention or inventions of Mr. Sawyer?

A. I do not think I gave it any consideration whatever, one way or the other.

X Q. 537. In view of the contract made on the date referred to, should you not say that it was your opinion at that time, that such inventions as had been made were the sole inventions of Mr. Sawyer, and such was his opinion?

A. If I look at nothing but that bare paper, dated March 19th, 1878, I might come to such conclusion, but in view of the facts as they existed and were known by both Mr. Sawyer and myself, I am confident that the authorship of invention was not one intended to be dealt with specially by that instrument. I am confirmed in this view of the subject-matter from a subsequent statement by Mr. Sawyer, in my presence, to Mr. Broadnax, at the time when the application for the patent in issue in another case, in October, 1878, was made, and in which interview both Mr. Sawyer and myself stated, as nearly as we possibly could, the facts about the invention, what each of us did, and took his advice as to whether the applications should be in Mr. Sawyer's name, in my name, or in our joint names, which advice we followed in making applications for our patents.

X Q. 538. Was this conversation with Mr. Sawyer, the first discussion whether your inventions had been joint, or were the separate inventions of Mr. Sawyer?

A. No.

X Q. 539. In view of the agreement made between you May 11th, 1878, which refers to the agreement of March 19th, please state whether it was not your opinion, at the time of the agreement
1186 of May 11th, and Mr. Sawyer's also, that the question of joint inventorship referred only to inventions made after March 19th, and in regard to those made before that period, they were the sole invention of Mr. Sawyer.

A. No, sir; the agreement of March 19th is referred to in the agreement of May 11th, only for particulars, and in the second clause of that agreement a reference is made to a prior agreement, and the plans proposed by Mr. Sawyer, and that second clause is the one stating the fact of my participation in the inventions. In explanation I wish to further say, it was not until after March 19th that it was demonstrated that the plans proposed by Mr. Sawyer therein referred to were futile.

X Q. 540. What were the plans of Mr. Sawyer, which you say were shown to be futile?

A. At this length of time I do not know that I can specify. I can only say that about the last days of March, 1878, Mr. Sawyer having failed to get anything ready to exhibit to my friends and myself, although I had aided him by suggestions, money and advice up to that time, was in despair about producing a light that would be satisfactory, and wanted more time to do it, and besought me not to leave him, as I was intending to do, and said if I would stick with him and help him that the thing could be worked out; and at that time it was considered that the plans he had proposed originally had failed.

X Q. 541. Cannot you give me any idea whatever as to those plans?

A. There was a lot of things, and I do not remember what they were; different forms of lamp; one, I remember, that the oxygen might be burned out of the air sufficient with phosphorus to leave a practical atmosphere of nitrogen for an incandescent lamp, and that a simple glass-stopper, like a bottle-stopper, would be sufficient sealing for the lamp. Another was burning out the oxygen in the lamp, and absorption of the carbonic acid by water. Another was that hydrocarbon gas would be a suitable atmosphere for an incandescent lamp. Another was that no special peculiarity of switch would be required. Possibly other things would occur to me, but these were some of them. 1187

X Q. 542. Is it, then, true, that in the latter part of March, 1878, Sawyer had failed to get anything satisfactory, and was in despair about getting up a light, and that you intended to leave him, and give the matter up?

A. It is true that up to that time I was not satisfied, although I saw at the same time great promise in many things we had done; and that I expressed to Mr. Sawyer my views on the subject, and that he expressed himself to me as in despair of accomplishing anything if I should leave him, and besought me to stay with him and help him, and, contrary to my better judgment, I did, and have been sorry for it that I did.

X Q. 543. Is it, then, true, that up to that time you had not accomplished anything?

A. No; it is not true that we had not accomplished anything. We had accomplished much, but we had not struck upon what I considered a practical system of incandescent lighting, and the things which Mr. Sawyer had proposed, had, it seemed to me, proved worthless, and what we had done that was of value up to that time, it seemed to me, was the result of my own suggestions and work with Mr. Sawyer, and I told him so.

X Q. 544. What was the cause of your dissatisfaction at this time?

A. Failure in accomplishment on the part of Mr. Sawyer.

X Q. 545. Failure in accomplishment of what?

A. In the making of a practical first-rate incandescent lamp with its accessories for an incandescent lighting system, and in what seemed to me a want of proper diligence and skill in the prosecution of the attempt. I can best illustrate it by saying that it 1188 seemed to me that when I was personally present and aiding and pushing the thing, things did not seem to progress, and seemed to me to remain at a standstill.

X Q. 546. Did you anticipate when you first made your arrangement with Mr. Sawyer that as early as the latter part of March, or within a month from the time experiments were begun, a "practical, first-rate incandescent electric lamp with its accessories for an incandescent lighting system," would be obtained?

A. I had anticipated that it would be done before the last of March.

X Q. 547. Were you impressed with the fact that on the part of Mr. Sawyer there was a want of proper diligence and skill in the attempt to obtain such a lamp and its accessories as far as he was concerned?

A. I have already testified that such was my feeling in regard to the matter, whether it was a fact or not might be a question of dispute.

X Q. 548. Was it your impression at the time referred to that Sawyer was not attending to his work diligently?

A. I have, I think answered that question as fully as I can.

X Q. 549. In what respect did you consider Sawyer lacking in skill?

A. Particularly in a knowledge of chemistry, and its manipulations, and in mechanical adaptations, and proportions, and in neglecting to note and profit by failures in experiments.

X Q. 550. You say Sawyer was lacking in what seemed to you a want of proper diligence in the prosecution of the attempt. How was this manifested? By absence from the laboratory or from inattention to work when there?

A. I do not know that I felt any dissatisfaction as to Sawyer's attendance at the laboratory, nor that he was not busy enough.

1189 X Q. 551. What do you mean by your answer when you say, "when I was not personally present, and aiding and pushing the thing, things did not seem to progress, and it seemed to me to remain at a standstill." I also call your attention to the other portion of the answer in which you say you were dissatisfied with Sawyer because of a want of proper diligence in prosecuting the attempt.

A. I mean just what I say exactly: I cannot better illustrate it than by reference to the common expression, "a man is very busy and does nothing," not that I mean to say that Mr. Sawyer did nothing or accomplish nothing, but that his accomplishments were not satisfactory to me, and it seemed to me to be due to a lack of proper and diligent, persistent, and well-directed attempt.

X Q. 552. Now, just what do you mean; was Sawyer diligent and industrious his work or was he not?

A. He seemed to me to be always busy; I cannot better express it.

X Q. 553. Were you satisfied or dissatisfied with the result of his labors?

A. I was not satisfied.

X Q. 554. What caused you to continue to assist him and why did you alter your conclusion to give the matter up?

A. I think as near as I can recollect, that I was influenced by Mr. Sawyer's urgent request, and his confident statement that if I would remain with him and assist him we could work the matter up to a practical and successful conclusion.

X Q. 555. When did differences first arise between yourself and Mr. Sawyer, and when were his habits of intoxication and dissipation first discovered or ascertained by you?

A. As near as I can recollect, the fall of 1878, while we were at the corner of Walker and Elm streets.

1190 X Q. 556. When did Sawyer first begin to neglect his work?

A. I now think that his habits interfered with his work all the time, but the first cause of complaint on my part of his conduct arose from his absence and nearly entire inattention to the work of the company while I was gone on my vacation in the summer of 1878.

X Q. 557. After the first complaint was not Mr. Sawyer's inattention to business and dissipation almost continuous from that period?

A. No, sir.

X Q. 558. I understand that Sawyer quarreled with the Electro Dynamic Light Co., and was the cause of a great deal of trouble to you and the various organizations with which he was connected, and became so dissipated as to utterly neglect his business. Now, please state when it was Sawyer's dissipation became known to you, how it became known, and what effect it had upon his attendance at your different laboratories, and upon his work while there.

A. Without consenting to your understanding, as stated in the question, exactly, I proceed to answer: My first knowledge of his dissipated habits and character, as near as I can recollect, was derived from information conveyed to me, I think, in October, 1878, of his conduct while I was absent on my vacation. I was told he had been on a spree, or a succession of sprees, during all this time. From this time forward I noticed from time to time in the morning, when I saw him at the shop, that he had been drinking. His dissipation was not such at any time while we were at 94 Walker street as to interfere with his ordinary attendance at the factory. I don't now recollect that I attributed any absence from the laboratory to dissipation, but perhaps I did at the time. Up to, I should now say, the 1st of November, 1878, I should think the effect upon his work while at the laboratory was confined to the effect of drinking 1191 before coming there, and not while at that place. While there I do not think he was drinking, certainly not to excess. From this time forward, that is, from about the first of November, the habit of drinking increased upon him, and interfered with his work so that I was compelled to give more time to the shop or laboratory than I could well spare from my other business, and finally, I think in December, Mr. Lawrence Myers went to the shop and staid there continuously day after day in order to relieve me and exercise a restraining influence upon Mr. Sawyer; it resulted at last, in the month of March, 1879, in the workshop of the company being closed up and the work being transferred to the shops of Wallace & Sons, at Ansonia, Conn., where Mr. Sawyer was to give his time and attention, for, I think, a period of four months. His conduct while there was such, both from habits of drinking and other dissipation, that Mr. Wallace, who had become president of the Electro Dynamic Light Co., made complaint of the same to the board, and refused to go on with him, and it was decided that this work should go on under the charge of Mr. E. L. Myers, who had been in our employ, and who was the only one except Mr. Sawyer and myself who understood all the details of our work and plans. Mr. Myers was taken sick and died, and after awhile the patents of the company were assigned to the Eastern Electric Manufacturing Co. This company had Mr. Sawyer in its employment, and had great trouble with him by reason of his intemperance and dissolute habits, and its patents were assigned to the plaintiff in this action, with whom Mr. Sawyer was never associated.

X Q. 560. Is it not the fact that Sawyer's habits and dissipation, after November, 1878, were of such a character as to seriously interfere with his work?

A. Yes.

X Q. 561. From your knowledge of Mr. Sawyer, in a case where it was his interest to make a false statement, is it your opinion that he would do so?

1192 A. I think it would depend upon his surroundings and circumstances at the time the statement was made and his condition at the time.

X Q. 562. From your knowledge of Mr. Sawyer, where it was, or he considered it to be, for his interest to make statements which were false, or to create the belief in others that things which were not facts existed, is it your opinion that he would do so?

A. I answer as before.

X Q. 563. Please explain your answer?

A. I mean that he would sometimes make, under certain conditions and circumstances, either false or true statements which were against his own interests, and he might be influenced in telling the truth or falsehood by passion, revenge, hatred, gratification of appetite, a desire to have his own way, or by conscience, remorse or desire to make amends.

X Q. 564. Would he make false statements in his own interests, or what he thought to be his own interests?

A. I do not think he was a reliable, truthful man. I do not, however, think that self-interest alone would be sufficient inducement for him to tell a falsehood.

X Q. 565. Do you think that Sawyer, if driven by necessity, could obtain money by making untruthful statements, or by deceiving the people from whom he expected to get it, would do so?

A. During the latter part of his life, driven sometimes by necessities brought upon himself, and sometimes by a desire to obtain means to gratify his appetites and passions, I believe him capable of doing so.

X Q. 566. Do you think he was capable of causing the formation of a company and the investment of money and the payment of money to himself to exploit inventions that he knew to be valueless, and would represent that he possessed patents which he knew to belong to others?

1193 A. Not from self-interest alone, but from hatred, malice, revenge or spite, to have his own way and accomplish his own or ulterior purpose—yes.

X Q. 567. Is it not the fact, whatever the motive may have been, that Sawyer did cause the formation of a company representing that he possessed inventions which he knew that he did not?

A. I believe it to be true. I do not know now that, from my own knowledge, I am able to assert it as a positive fact. I have tried to forget as much as possible these things against Mr. Sawyer. I believe that a refreshment of my recollection would compel me to assert it as a fact, but I don't want to do so.

X Q. 568. Did you ever know of Sawyer's blackmailing one or more of the companies with which he and you were connected, and obtaining money from them by threats, and compelling the payment of money to himself by false representations or threats?

A. I believe he did.

X Q. 569. Was not Sawyer a man of utterly bad character, capable of dishonest or dishonorable acts?

A. No; not until at least the latter part of his lifetime was he utterly bad. He died in 1882, and, indeed, I don't think he was utterly bad ever; he loved his little children, even then. He was capable of, and did, in the few last days of his life, send for a friend whom he had injured, and when that friend refused to go to see him, sent word that he did not want money, but wanted his forgiveness. Nevertheless, he was very bad, and did not hesitate afterwards to malign this very friend. No; he was not utterly bad.

X Q. 570. Do you mean that he was not utterly bad until the latter part of his life, or that you did not know that he was?

A. I knew he was very much worse during the latter part of his life, and that I did not know of his being a bad man in 1878, except for his inebriate habits.

1194 X Q. 571. Have you ever known of his committing perjury?

A. I don't think I can say, of my own knowledge independently, that he committed perjury.

X Q. 572. Do you think he was capable of doing so?

A. I have already answed that question in my answer, or answers, as to his truthfulness. I will answer in the same way, adding that, if the circumstances were such as to induce him to do it, I think he might have done so.

X Q. 573. Are you familiar with what was his general reputation for truth and veracity among his business associates in the various companies that have been mentioned?

A. I do not know that I would be a competent witness upon that point. My knowledge of his reputation was somewhat limited; however, I know something of it.

X Q. 574. From your knowledge of his general reputation for truth and veracity, would you have believed him under oath?

A. From my knowledge of his reputation, speaking from that alone, without any reference to my personal knowledge of the man, I should say that it would be necessary to know his circumstances, surroundings and the influences at work upon him at the time of his declaration under oath before I could say that I would believe or disbelieve him.

X Q. 575. Prior to your association with Mr. Sawyer did you consider yourself an electrician?

A. Only theoretically; I was not a practical electrician. My main knowledge derived only from reading and observation. It had been a favorite study of mine for some years before that time. I had considered the subject of electric lighting in connection with other matters of electrial interest only—not as a specialty.

1195 X Q. 576. Did you read or were you familiar with such patents on the subject of electric lighting, either by the arc or by incandescence as had been taken out prior to your connection with Mr. Sawyer?

A. I do not as patents. I had read and was familiar with the labors and investigations of others relating to this subject, so far as the same as published had come to my attention in the scientific journals and reports.

X Q. 577. Had they come to your attention to a sufficient degree to familiarize you with the labors and investigations of others in this art?

A. I think so, to a very considerable extent.

X Q. 578. At the time of your meeting with Mr. Sawyer, was he familiar, in your judgment, with the labors and investigations of others in this department?

A. He seemed to me to be quite familiar with the history of the subject.

X Q. 579. Referring now to the dynamo machines, which you used in your experiments, I understand your recollection to be as follows: That for the first two or three days at Centre street there was an Arnoux & Hochausen light machine in the basement of the building; that after that was removed, and until about March 25th, you borrowed some plating machines from Arnoux & Hochausen; on or about March 25th a specially wound machine was delivered; that after you went to Howard street and from there to Walker and Elm streets another specially wound machine was obtained; that from then on you used the specially wound machines, and occasionally one of Arnoux & Hochausen plating machines. Is this correct?

A. The exact details will better appear in my testimony as given.

X Q. 580. Describe in detail the construction of the machine which was specially wound for you in Centre street and delivered to you March 25th.

A. I cannot do so without the machine being present.

X Q. 581. Do you not remember them sufficiently well to describe it?

1196 A. No, not in detail.

X Q. 582. Describe it as well as you can?

A. It was an ordinary type of Siemen's H armature dynamo, about two and a half or three feet long, and the same height, say two and a half feet.

X Q. 583. Please state the construction of the field magnets of this machine?

A. I could not do it.

X Q. 584. Were they permanent or electro-magnets?

A. Electro-magnets.

X Q. 585. How were the magnets energized in your experiments with this machine?

A. Ordinarily by the current evolved by the machine, but in some experiments by a separate machine.

X Q. 586. Please describe completely the connections made where the magnets were energized by another machine, and where they were energized by the machine itself?

A. I cannot recollect the details of these connections more than any other electrical connections.

X Q. 587. If this machine were now before you would you be able to make the proper connections to energize the field by the machine itself, or in the other case by a separate machine?

A. I think so; if the machine was so constructed as to permit it.

X Q. 588. Please state what you would do to make the connections suggested, and illustrate the same by a sketch?

A. I do not know how you could expect me to construct a machine of which I have told you I have no recollections of its details. I decline to do it.

X Q. 589. Please describe the "ordinary Seaman's H armature machine"?

A. I have never built a dynamo. I have never made any invention of a dynamo; my knowledge in regard to dynamos is wholly theoretical, derived from books and descriptions; in giving a description of Seaman's H armature machine, I am liable to omit details and perhaps essential parts. If you desire to have me make a description I will do so as well as I am able. 1197

X Q. 590. Describe the ordinary Seaman's H armature machine.

A. Suppose an iron frame in the form of the letter H, pivoted on a shaft parallel to two sides of the letter and midway between them, the cross-piece of the H extended so as to give it more of the form of an ordinary reel for winding up yarn or fishing line by hand. Let this iron frame be wound lengthwise between the sides of the

H with insulated copper wire until it assumes the form of a cylinder or nearly such, the two ends of the wire being brought out and insulated to near the ends of the axis where they are in communication with insulated semi-cylinder plates of metal, embracing and nearly surrounding the axis, called a commutator. Resting upon these and insulated, two brushes or spring plates touching opposite portions of the commutator plates last described; a pulley connected to the axis of the armature, by which it may be driven; supports in which the axis revolves; field magnets, or magnets whose opposite poles substantially embraces the armature. These are the essential features of construction; the field magnets may be permanent magnets or electro-magnets, and in the latter case may be actuated by the current of the machine, a portion of the current in a shunt circuit, or by a current derived from a battery or other machine.

X Q. 591. Are machines of this type always provided with commutators such as you have described?

A. I don't know that I have described any particular kind of commutator except such as is generally used; if no commutator were used the currents would be to and fro, or alternate.

1198 X Q. 592. Please state the length and shape of the magnets of the specially wound machine to which we refer—that delivered in March, 1878.

A. I do not recollect them well enough to describe them with accuracy; I only recollect they were broad lengthwise of the machine and their poles projected upward.

X Q. 593. Please state the weight of the machine.

A. I don't know; two men could lift it.

X Q. 594. What was the size of the wire of the field and armature?

A. I don't recollect.

X Q. 595. How many turns of wire were there on the armature?

A. I say I cannot recollect the details; I never knew.

X Q. 596. What was the resistance of the armature and of the field?

A. I don't know.

X Q. 597. State approximately or as near as you can.

A. I have no recollection.

X Q. 598. In the experiments with this machine where the magnets were energized by the currents of the machine, was the magnet connected in series with the armature or in multiple arc with it?

A. I don't recollect whether the whole currents were sent around the field magnet or whether they were connected in a shunt circuit.

X Q. 599. Do you know what the difference between these two methods of connection would be, with reference to the electrical apparatus or lamps operated by the machine?

A. I don't think anybody could tell without a thorough knowledge of the machine in a given case, and without a knowledge of the number of appliances, their resistances and relation to the circuit, and without knowing whether the re-entering point of 1199 the shunt was before or after the appliances to which you refer in the general circuit.

X Q. 600. Answer me with reference to the machine in question and to the experiments of Sawyer and Man.

A. I do not recollect how it was connected, and therefore cannot tell you how it operated one way or the other.

X Q. 601. What was the electro-motive force of this machine?

A. I don't recollect; I guess some twenty-five or thirty volts; it may have been much more or it may have been less.

X Q. 602. And you don't now recollect it?

A. I don't know.

X Q. 603. Do you mean to say that you cannot state what the electro-motive force of the machine was, that was specially made for you, and used by you throughout your experiments?

A. I do mean to say that I cannot recollect what it was.

X Q. 604. Will you swear that it was over five volts?

A. I think that it was very much more than that; but I do swear at the same time, I don't know anything about it.

X Q. 605. What was the E. M. F. of the machine that you borrowed from Arnoux & Hochausen in Centre and Howard streets?

A. I don't know.

X Q. 606. About what?

A. I don't know.

X Q. 607. Can you not give any idea?

A. I have no recollection.

X Q. 608. More than one volt?

A. You have exhausted my recollection in regard to this matter, so far as giving details of electrical measurements is con- 1200 cerned; the machines we used were perhaps not all of them measured, and I don't recollect them with sufficient accuracy to give the details of their electrical measurement in any case; it would, however, from the work they accomplished, as a general rule, be absurd to estimate the electro-motive force of any of them so low as one volt, as it seems to me.

X Q. 609. Was it more than two volts?

A. I have nothing to add to the explanation I have just made.

X Q. 610. Was it more than three volts?

A. I think the machines we used would probably be estimated from thirty to two hundred volts; you drive me to make a guess in regard to it; it is all that I can say and I don't know that I am right.

X Q. 611. The machines you used have been specially pointed out in the testimony; what was the E. M. F. of the electroplating machines borrowed by you from Arnoux & Hochausen, and which you say were a type of machines made by them and sold in the open market; do you mean to say it was between thirty and two hundred volts?

A. If they had been pointed out it has been an error on my part, for I have intended to be understood as not recollecting specifically the different machines that we used; we did use plating machines, and those principally at the corner of Howard and Centre street, and part of the time at 43 Centre street; whether we used any other than plating machines at the corner of Howard and Centre streets I do not recollect, except our own first machine we used at 43 Centre street, and at 94 Walker street lighting machines built by Arnoux & Hochausen; the E. M. F. of the plating machines was not high as compared with the lighting machines nor as compared with our own machines built by Arnoux & Hochausen, nor as compared with the machine whose field magnets were energized by another machine.

X Q. 612. Question repeated.

A. I don't know.

1201 X Q. 613. Do you wish then to be understood as being able to give no idea whatsoever as to the E. M. F. of the machines which were loaned you and used by you in experiments? I refer to machines which you stated were plating machines made by Arnoux & Hochausen, and sold for that purpose in the open market.

A. Your question implies inaccurately that I can give no idea, or have given no idea whatever in regard to the subject-matter. I therefore decline further to answer it.

X Q. 614. Please state what was the E. M. F. of the plating machines made by Arnoux & Hochausen and sold for that purpose in the open market, and which were borrowed by you and used in your experiments.

A. The E. M. F. of different machines which we borrowed and used including the different plating machines was widely different one from the other, and we coupled them to produce different E. M. F. as we used them, but I have no recollection whatever what the E. M. F. was as a matter of recollection.

X Q. 615. I restricted my last question, and restrict this to such electroplating machines as you borrowed of Arnoux & Hochausen. I wish to know what the E. M. F. of those machines—not other machines—but those machines, was. Please state.

A. The electro-motive force of these machines greatly varied one from the other. I mean the electroplating machines that we borrowed and used. I don't know the E. M. F. of any of them. I don't know the highest E. M. F. obtained from any of them, nor the E. M. F. that could be obtained from any combination of them; nor the lowest E. M. F. of any one of them; nor the range by which the E. M. F. varied from the highest to lowest.

X Q. 616. Did you ever hear of an electroplating machine of over 15 volts?

A. I don't remember to have ever heard the E. M. F. of any plating machine spoken of.

1202 X Q. 617. Does not your investigation into this favorite study of electricity enable you to state what the E. M. F. of plating machines usually is?

A. I do not remember to have ever looked into the subject; doubtless Mr. Edison, from his experience with his electric meter, could give you the information you seek.

X Q. 618. Then, as I understand you, you have no idea whether the E. M. F. of these electroplating machines was as low as half a volt or as high as 10,000 volts?

A. I have no question as to your understanding, and deny all responsibility for the same.

X Q. 619. Have you any idea as to the E. M. F. of the plating machines sold by Arnoux & Hochausen while you were at 43 Centre street?

A. I don't know what the E. M. F. of those machines, or any of them was.

X Q. 620. Do you know whether it was above or below 15 volts?

A. I think, as a rule, it was much above; I don't know.

X Q. 621. How much, then, do you think it was?

A. I have already said that I guessed their E. M. F. was 25 or 30 volts.

X Q. 622. Confining ourselves to the electroplating machines which you borrowed while at 43 Centre street, of Arnoux & Hochausen, what is your best recollection of the number of such machines that were borrowed while you were there?

A. I don't recollect how many they were of them. There were several; I should think in all five or six different machines—possibly more.

X Q. 623. Were they of the same size and character?

A. Their type was similar but some of them were very much larger than others.

1203 X Q. 624. How did they vary as far as their electric effects were concerned, if at all?

A. Some of them were very much more efficient for lighting purposes, and would light up a much larger number of our lamps than others, and some of them would alone send a current through carbon for the first time, when it was being heated in hydrocarbon gas, sufficient to bring the carbon up to incandescence, and some of them would not—that is to say, both their electro-motive force and quantity greatly vary.

X Q. 625. Please state, as nearly as you can, within what limits this variation in electro-motive force and quantity was?

A. I cannot give it in terms of electrical measurement.

X Q. 626. Have you no idea of it?

Q. I have no recollection of it sufficient to express it in terms of accuracy or electrical measurement.

X Q. 627. Can you not give me any idea?

A. I prefer not to guess at the matter.

X Q. 628. What I desire to know is, whether it is true that while you were at No. 43 Centre street you borrowed from Arnoux & Hochausen five or six different plating machines; second, whether these different machines differed in construction and electrical effect, or whether some of them, or all of them, were alike.

A. What I said, and intended to be understood, is that while at 43 Centre street we borrowed and used several machines of Arnoux & Hochauson of the general type and character of machines in appearance, which they built and sold for electroplating; that I es-

timated their number at five or six—it may be more or less. It may be that not all of the machines were intended by them for electroplating; they may have intended some of them for electric lighting, in which they were also engaged, but I took them to be, if I
recollect right, their plating machines. The general con-
1204 struction of the machines, except one that was in the base-
ment, and which they used for electric lighting, and which
they let us have the use of for a day or two, or so, was similar. I think there were three sizes of them; those of the same size were more nearly alike in electrical effect probably, but no two of the machines were alike in effect.

X Q. 629. I understand you to say that with the exception of the light machine in the basement, the five or six machines which you understood to be plating machines, and which you borrowed of Arnoux & Hochausen, were alike in construction, but were of three different sizes. Now, were these machines which were of the same size wound in the same way, with the same wire, and designed to be of the same effect electrically?

A. Excuse me from testifying to the accuracy or inaccuracy of your understanding. To your question alone I reply. I do not know how the machines were wound, nor with what wire. I only know that they differed one from the other in electrical effect.

X Q. 630. Were those machines which were of the same size of such difference in electrical effect as to have been designedly so, or was the difference merely such as would exist between machines of the same size and character and intended to produce the same results?

A. I think the difference in electrical effect of machines of the same size, was due to design and experiments on the part of Mr. Hochausen, but I am not certain of this, and it may have been due to selection among different machines intended in construction to be the same.

X Q. 631. In machines of the same size, what was the difference in E. M. F.?

A. Some of these machines of the same size differed widely in E. M. F. I cannot give the difference in volts.

X Q. 632. As much as 100 volts?
1205 A. I should think not, but as I have said, I don't know.
If you wish me to guess I will do so, but it will be a guess.

X Q. 633. As much as 50 volts?

A. I don't know.

X Q. 634. As much as 10 volts?

A. I think so; I don't know.

X Q. 635. As much as 15?

A. I think so; I don't know.

X Q. 636. As much as 25?

A. I think so; I don't know.

X Q. 637. As much as 40?

A. I guess so; I don't know. The average E. M. F. I have guessed at or estimated as 25 or 30 volts. It will not surprise me to know that some of these machines had not 5 volts of E. M. F., and that another machine of the same size and general appearance might actually have had in the neighborhood of 200 volts E. M. F.

X Q. 638. Do you mean that of these machines which you took for plating machines, and which were borrowed from Arnoux & Hochausen, while you were at 43 Centre street, which were of the same size, may have varied in E. M. F. from 5 to 200 volts, and that you would not be surprised at such being the case?

A. I mean exactly this: that I never knew or heard of but one or two of these machines being measured. That I noticed in our experiments from time to time, a wide difference in the E. M. F. of these machines, and that if any competent electrician should have measured two machines of the same size and told me then or tell me now that one measured but 5 volts and the other measured 200 volts, I would not doubt, and would have no means that I recollect of now to doubt the accuracy of his statement, and the same would be true if he should report to me that one measured 3 volts and the other 30.

X Q. 639. What was the difference in E. M. F. of those machines which were measured?

1206 A. I do not recollect.

X Q. 640. Can you give me any idea?

A. No; and I don't know that two were measured, but I think they were.

X Q. 641. What machine, or which machines were measured for electro-motive force?

A. To the best of my recollection the machine we bought of Arnoux & Hochausen and the machine we borrowed of them, and which seemed nearest like it in electrical effect.

X Q. 642. Do you know upon what the E. M. F. of a dynamo depends?

A. I think I know some of the causes. I have never made a study of dynamos particularly.

X Q. 643. What are they?

A. Velocity of motion in the armature; size of the resistance in the wires of the armature; and density of magnetism in the field of the field magnets, through which the wires of the armature move.

X Q. 644. Please explain what the size and resistance of the wires of the armature have to do with the E. M. F. of the machine?

A. I do not propose to go into a theoretical discussion of electrical subjects.

X Q. 645. Do you decline to answer my question, or are you incapable of doing so?

A. I decline to answer it.

X Q. 646. Are you quite certain that you know the conditions which enter into the E. M. F. of a machine?

A. I do not think that I am called upon to discuss this subject-matter with you or to express an opinion as to my own abilities.

X Q. 647. Question repeated. (Witness is silent.)

The witness has declined to answer, and is instructed by counsel not to undertake to testify as an expert on matters pertaining 1207 to dynamos unless he feels himself competent as an expert and unless the court compels him, and counsel submits to the court, whether, in view of the facts that the witness has testified, that he has not made any dynamos, or experimented with them, and knows nothing of them only as a matter of theory, he must answer the question.

The witness himself further objects, that he has not submitted himself to an examination-in-chief on the part of the defendant, and that if defendant desired to test the electrical knowledge of the witness, or to obtain expert testimony from him, he must first obtain the consent of the witness to testify and pay him therefor.

X Q. 648. Please state what you mean by density in magnetism in the field of the field magnets in your answer.

A. The number of lines of force in the field of those magnets for a given space determines the density of the magnetism in that field of force, and the number of these lines is increased as the magnetism of the field magnets is increased up to the point of saturation.

X Q. 649. These machines which were borrowed of Arnoux & Hochausen, at 43 Centre street, had they any name or designation by which they were known in the business, and if so please state what it was?

A. I don't know of any.

X Q. 650. What was the weight of those borrowed machines; how did you get them into the room in Centre street, and who placed them there?

A. I never knew their weight; they were hoisted up in a hoistway to the floor on which our shop was. I think they were got into the room by old Mr. Sawyer, George and the men at work in the different shops there, and placed under the direction of Mr. Wm. E. Sawyer.

X Q. 651. The machine which was bought of Arnoux & Hochausen, while in Centre street, and which has been described as the specially wound machine, please state why it was specially 1208 wound; how it was specially wound, and what the effect of this special winding was.

A. As I have stated I do not recollect any of the details of this special winding. I only know that this machine was a very much more effective one than the others.

X Q. 652. Do you mean that you gave no instructions as to how you wanted the machine made, but merely stated that you wanted a machine to produce certain results, leaving them to ascertain how such results were to be brought about?

A. No, I don't think that that is quite right. I think it was about like this: We had tried several of Arnoux & Hochausen's machines, one of which was intended for arc lighting. We discussed with Mr. Hochausen the matter of building a machine which would be more effective for our purpose of incandescent lighting than any of those we had used. At the time I knew nothing about dynamos, except what little I had read, and the small experience I had obtained from the use of those that we had had so far. I don't know that any of us knew much about it. Mr. Hochausen had had the most experience and knew most, and I think they agreed to wind the machine over again if it did not prove satisfactory.

X Q. 653. What were the properties of a machine that you considered at that time as effective for incandescent lighting?

A. The one that would heat up the most lamps to the highest degree with the power.

X Q. 654. Was that the definite information that you conveyed to Mr. Hochausen?

A. At that time just as definite as that.

X Q. 655. Did you want high or low E. M. F.?

A. We thought we wanted a greater quantity of current in pro-
portion to its intensity than his arc-light machines gave, and
1209 a greater intensity than the other machines gave, that is,
less E. M. F. than the arc-lighting machines and more than
the plating machines.

X Q. 656. What amount of E. M. F. did you want to get by this specially wound machine?

A. We did not know ourselves.

X Q. 657. Did you know approximately?

A. No, only somewhere between the E. M. F. of the arc-lighting machine and that of the plating machines, as we judged from experiments.

X Q. 658. Did you know what the E. M. F. of the lighting machines that were in the basement for a day or two and of the plating machines were?

A. No, only in effects, not in electrical units.

X Q. 659. Please state what the effects were which enabled you to judge of the E. M. F. of this light machine, and of the plating machines.

A. The one would light up several lamps of a high resistance, and would send a current through fine carbon before it had been treated and its resistance reduced; the little plating machine would heat up several lamps of low resistance with large carbons in them, after they had been treated, about as well as the large lighting machine, but would not send a current through carbon that had not been treated of high resistance without forcing to start it, by making and breaking the connections rapidly and suddenly.

X Q. 660. Was the specially wound machine of greater E. M. F. than the plating machines?

A. At first, yes; and it also gave a larger current under the resistance with which we used it.

X Q. 661. What do you mean by "at first" in your last answer?

A. Just what I say. It was rewound several times.

X Q. 662. How many different times was the machine wound, and by whom was it wound?

A. By Arnoux & Hochausen, I think twice after the first winding, perhaps three times.

1210 X Q. 663. What was it that was rewound?

A. I think the armature alone at one time—perhaps the armature alone twice; once I think the whole machine was rewound.

X Q. 664. State, as nearly as you now recollect, when these several rewindings were done?

A. The first, I think, was soon after we first received it, and while we were at 43 Centre street. I think it was again wound while at Centre street. The final winding was while we were at 94 Walker street.

X Q. 665. Please state what the nature of the first rewinding was, and what effect it had upon the machines?

A. I did not see the work done, and, therefore, can only state generally what I understood was to be done, and what I assumed from the results was done. The armature was rewound with finer wire and differently connected up, for the purpose of giving the machine greater E. M. F.

X Q. 666. What was the difference between the connections as rewound and its connections prior to that time?

A. I can only answer as before from my understanding of what was to be done, and from the results obtained. I understood that the machine was to be coupled up more in series than before. I neither did this work myself, nor saw it done, nor supervised it. All that I had to do was to talk about it and advise about it beforehand. Judging from the effect, I assume it was done.

X Q. 668. Do you mean that now the armature was in series with the magnets, whereas, before, it had been in multiple arc with them, or that such was your understanding?

A. No. I had reference to the armature alone. Perhaps my expression "more in series" does not convey a correct impression. The armature first being wound with coarser wire in several separate coils connected to the commu*nic*ator; by the use of a
1211 finer wire, a larger number of coils was produced, occupying
the same space, and having a greater length than the coils of coarse wire; they were connected up perhaps one coil to another in series, or two or more coils were united before connection to the commutator.

X Q. 669. How much was the E. M. F. of the machine increased by this operation?

A. I don't know.

X Q. 670. Can you state approximately?

A. No; I can only state results; it was largely increased.

X Q. 671. About how long after the machine was first delivered was this rewinding done.

A. I cannot remember, but my impression is not very long. My attention being called to this matter, my impression is that some change was made in the winding of the field magnets soon after the first change in the winding of the armature of this machine, or it may have been before the change in the winding of the armature. I think the field magnets were first connected up in series with the armature, and that they received a compound winding in connection after we got the machine.

X Q. 672. What was the nature of the second rewinding, when was it done, and what was its effect?

A. I think the second rewinding was rendered necessary by burning out some of the coils of the armature of the machine. I do not remember that any discussion was had in regard to it, and as I did not give it personal attention I do not think I could give any other description of it. I do not remember that it affected particularly the working of the machine; if anything, it increased the quantity, but left the E. M. F. about the same.

X Q. 673. What was the nature of the third rewinding, when was it done, and what was its effect?

A. I think the third rewinding was done after we went to 94 Walker street. I only recollect about it, that it was our object at that time to get a machine of greater quantity current. I did not see it done, but assume that a larger wire was used in winding the armature in separate coils as before, more connected up in multiple arc to the commutator for the purpose of giving quantity than was the previous winding. I do not remember whether the field magnets were rewound here or not; nor whether they were connected up differently from what they had been. We got a machine with a current of larger quantity and less E. M. F. 1212

X Q. 674. Do you remember how much the E. M. F. was reduced, or approximately?

A. I do not, to give it in terms of electrical units, but as a fact I think it was not very much reduced, while the quantity, I think, was largely increased.

X Q. 675. Please describe the machine which you had specially made for you while at 94 Walker street.

A. I do not think I could describe it except in a general manner. I should think that it would weigh possibly 1,000 or 1,200 pounds, and from that up to a ton. It had a series of field magnets, I should think, set around a circumference, within which revolve the armature. It was of the type of machine built by Arnoux & Hochausen for arc electric lighting, but either its winding or connections were such as to give current of less E. M. F. and larger quantity than their ordinary arc electric light machines. It stood about 2½ feet high; was, I think, something over 2 feet in diameter, and 2 to 2½ feet in length. I am speaking of this machine without having seen it, or one like it, for some seven years.

X Q. 676. Can you remember the size of the wires of the magnets or armature, the nature of the windings and connections, and the E. M. F. of the machine? If so, please state them.

A. I cannot; I can only remember what we did with it.

1213 X Q. 677. I have gone over in detail the various dynamo machines which were used by you in your experiments, and I understand that you are unable to describe these machines in detail, to state in detail the size of the wires with which the magnets or armatures were wound, or to give in detail in electric units the electro-motive force or quantity of the machines. Am I correct in so understanding?

A. It is true that I cannot describe with accuracy the machines which we used, nor give in detail in regard to them the particulars of which you speak, whether all of the machines which we used have been gone over by you or not.

X Q. 678. What has become of the machine that was bought while you were in Howard street?

A. I think that machine was taken to Ansonia, Conn., by Thos. Wallace.

X Q. 679. I understand that that machine belonged to the Electro Dynamic Light Company. Can you inform me where that machine now is, and under whose control?

A. I do not know, but assume that Mr. Thos. Wallace has it.

X Q. 681. The machine ordered in Centre street I understand to be in your possession at your place in Georgia?

A. It is in my possession at Garnett's, near Dahlonega.

X Q. 682. Do you remember at what velocities the armatures of these machines were driven?

A. The smaller machine was run from 1,600 to 2,000 revolutions per minute; the larger machine from 12 to 1,600, according to the best of my recollection.

X Q. 683. In one of your answers you speak of the arc-light machine which was in the basement for a day or two as one that "would light up several lamps of high resistance, and would send a current through fine carbon before it had been treated, and its resistance reduced." Is this an inference of your own, or do you mean
1214 to be understood that it did do, by actual work, that which you say it could do?

A. I mean to say that it did it, while we were using it there, the work I mentioned. I think that I used the expression "within a day or two," that may be correct, or it may have been a longer period, as I have several times endeavored to express myself since using the expression.

New York, *July* 20, 1887.

Met pursuant to arrangement of counsel.

Present, counsel as before, and the cross-examination of Mr. Man was continued as follows:

X Q. 684. Referring to your 7th answer on your examination-in-chief, what did you, and do you, consider to be the invention or improvement covered by the first claim of the patent in suit?

Objected to as incompetent, on the ground that the patent is the best evidence, and the only evidence by which the invention, covered by it, can be ascertained.

A. I cannot state it more accurately than is stated in the claim, which is as follows:

"An incandescent conductor for an electric lamp of carbonized fibrous or textile material, and of an arch or horseshoe shape, substantially as hereinbefore set forth."

X Q. 685. Do you understand the word "substantially as hereinbefore set forth" to define, in any way, the invention?

Objected to as incompetent and immaterial.

A. I don't know what their effect is.

X Q. 686. If these words had been left out would you regard the invention the same as you do now?

Same objection.

1215 A. I suppose the invention would be sufficiently described for claiming with these words omitted. Whether they add or detract anything is a matter of opinion. I don't profess to know.

X Q. 687. Do you regard the invention of that claim to be an incandescent conductor for an electric lamp of carbonized fibrous or textile material and of an arch or horseshoe shape?

Same objection, and further that the question is a mere repetition of the claim.

A. I regard that claim as covering such an invention.

X Q. 688. Do you regard it as covering any other, or further, invention?

Objected to as incompetent and immaterial.

A. So far as the words of the claim having reference to the specification of the patent add to, or amplify the claim, or are necessary to its understanding, yes.

X Q. 689. What invention, different or other than as stated in my 687th question do you regard the invention of the claim as covering?

Same objection.

A. The specification in speaking of the advantages of manufacturing the carbon from vegetable, fibrous or textile material, speaks of the convenience afforded for cutting and making the conductor in the desired form and size, the purity and equality of the carbon obtained, its susceptibility to tempering both as to hardness and resistance, its toughness and durability. They also speak of the advantages derived from the particular form of the conductor mentioned in this claim, and it seems to me, though I may be wrong, that these descriptions do amplify the claim as set forth to a something beyond what you state in your question. Just how much or how far this goes, I am unable to define, and I may not be right in my supposition. I will explain by saying that a mere conductor of unsuitable size, though of the shape and material mentioned, might be entirely unsuited to the purposes of electric lighting as ordinarily practised with incandescent lamps. It might be as big as your leg or as long as a ship's cable and utterly unfit for the purposes intended, though of the material and shape mentioned in the claim. So that it seems to me that the claim should be taken with the specification in a reasonable man- 1216 ner, and I think the court is the proper party to judge of what it covers and what the invention is, that is, I have reference to its limits.

X Q. 690. I do not request from you a construction of the claim of the patent to which you are referring, but inasmuch as you were asked on your direct examination to read the claim "and state when the invention or improvement covered by that claim was made," to which you replied—"In the month of March or April, 1878"—I desire to know what you understood to be the invention or improvement when answering the question. Please tell me.

Same objection.

A. The invention or improvements stated in the claim which I then read. I can't state it better. Any further answer would be to construe the claim.

X Q. 691. Is this your position; that whatever the court may hold to be the invention covered by that claim, was made by you and Mr. Sawyer in the month of March or April, 1878, but that you are now unable to say what that invention was?

Same objections, and as improper in that it assumes that the court would construe the claim to mean something not stated by the claim, and that it is not competent for the witness to testify that he has any other understanding of the invention than that described by the language of the claim as a part of the specification.

A. I do not stultify myself in that way.

X Q. 692. When you made your answer to question 7 what was the invention or improvement you then stated to have been made in the month of March or April, 1878?

1217 Objected to as incompetent and immaterial.

A. I have already answered that and the words of the claim answer it.

X Q. 693. The trouble is this: The question referred to did not define or state any invention, but asked when the invention covered by the first claim was made. Now what the invention may be is a question of construction for the court, but I take it that the counsel must have assumed that you had some definite understanding as to what the invention was that was covered by that claim and I infer that you must have understood what or considered the invention or improvement covered by that claim to be, when you say it was made in the month of March or April, 1878. When I ask what you understood to be the invention you read me the claim of the patent in suit. Now it may be hereafter said by the court that the invention covered by that claim is one of several things. Can you not, therefore, tell me what, when answering the seventh question you understood the invention or improvement to be, which was made in the month of March or April, 1878?

Objected to.

1st Upon the ground that the question don't fairly state what the question of the counsel was, inasmuch as counsel did state by putting the patent itself in the hands of the witness, what the invention was, referred to by his question, and

2d. That the question is improper in that it calls upon the witness for a construction of the claim which in its terms is a statement of the invention.

3d. If the court construes the invention to be anything different from that stated by the claim it would be impossible for the witness to know when such invention was made, and

4th. Upon the ground that it is immaterial what the witness thought that the invention was, and improper for him to testify, that he thought it was anything different from that stated by the patent, since every one who may be interested in or who 1218 deals with the patent must be governed by the language of the specification and claim, and that the witness, who is one of the inventors, cannot be permitted to say that the invention was anything else than that stated in the patent.

A. When the 7th Q. was put to me I was already familiar with and then recently read over the whole patent, specification and claims. I had myself drawn or aided in drawing the claim in question putting it in the best language I could to state succinctly the invention or a part of it, which the patent was intended to cover as a whole. Immediately preceding the claim 1 in the patent are the words "we claim as our invention," then follows claim 1 which I understood and now understand to be a clear, concise and succinct statement of an invention or of the thing found out by us. I understood the word "cover" in the question to mean "stated" in the claim; in such sense I answered it as I did. In answering I intended and meant nothing whatever that is not stated in the patent, specification and claim, and I meant all that was stated in the specification of the patent and in this claim so far as it is applicable to the things stated in the specification. In answering your previous question I must be understood as answering with this limitation and not as assuming that the court would decide that anything not in the patent was covered by it, but that it might in its discretion limit the invention stated in the claim by words contained elsewhere in the patent and that it would have to refer to those words in the construction of the claim.

X Q. 694. Have you any different understanding now of what the invention covered by the first claim is, than when you answered question seven.

A. No.

X Q. 695. Do you regard the language of the claim as clearly stating what the invention is?

Objected to as incompetent and immaterial.

1219 A. Taken in connection with the whole patent, yes.

X Q. 696. By "taken in connection with the whole patent," do you mean that the invention of the first claim is explained by the specifications and drawings?

Same objections.

A. I think what it meant is rendered clearer therein.

X Q. 697. Do you recognize it as possible that any difference of opinion might exist as to what the invention covered by the first claim is?

Same objections.

A. Human language cannot be framed to remove all possible question that may arise in regard to its meaning in the future; in that sense I recognize it as possible that questions may be raised about this claim; I do not recognize it as a probability; or perhaps I had better say as a difficult question for the court to determine.

X Q. 698. Do you regard it as possible that after a careful reading of the entire patent a difference of opinion could exist as to what the invention covered by this first claim is?

Same objections.

A. I do not concern myself in regard to it.

X Q. 699. That may be, but I would like you to answer my last question.

Same objections.

A. I don't know whether it would or not; if the opinion were an unprejudiced one I think not.

Adjourned till Thursday the 21st inst., at 1 p. m.

1220 THURSDAY, *July* 21, 1887.

Met. Present: Counsel as before.

Cross-examination of Mr. MAN continued:

X Q. 700. Do you regard cutting the material to size before carbonization as a feature or part of the invention of the first claim?

Same objections, and as calling upon the inventor to vary or construe the claim and specification of the patent.

A. I am one of the inventors. In the preparation of the specification and claims of this patent, in making the claims including the first claim, I considered them as analagous to the syllabus of a case or proposition, or theorem in geometry, and endeavored in concise language therein to state the invention or inventions we had made. I have parted with all my interest in the patent, and I do not feel myself at liberty to give construction, alter or vary the statement of the invention contained in the patent, to enlarge or diminish it, or to give construction to it. In answering the question No. 7 of the examination-in-chief, I understood the question as meaning to ask me when the invention stated in claim 1 was made. I then considered, and now consider that that claim states an invention. Whether it does or not, I am not called upon to decide, but understand that to be a question for the court. My answer, then, to question 7 is to be construed, and I wish it to be so, that if claim 1 states any invention, that invention was made at the time specified in my answer. I decline to give construction to the claim or state my views in regard to what it covers, but I will answer any questions in regard to what we did which are pertinent and proper.

X Q. 701. I am trying to get at what your understanding of the invention of the first claim was when you answered question
1221 7. Please state, therefore, whether you then considered cutting the material to size before carbonization as a feature of the invention of that claim.

Objected to as incompetent and immaterial and as calling upon the witness to construe the claim and specification of the patent.

A. I considered the invention to be just what it is stated in the patent.

Answer objected to as irresponsive.

X Q. 702. Question repeated.

Same objections.

A. I can only state that the patent refers to the cutting of the material to size before carbonization, that we did so cut the material to size before carbonization at the time mentioned in my answer, in the spring of 1878; that we used the carbons so prepared, and others manufactured from material reduced to size before carbonization in one or more directions, and that if the claim should be held by the court to cover the cutting to size before carbonization, my answer would include it.

Answer objected to as irresponsive.

X Q. 703. Question repeated.

Objected to as having been already answered very fully by the witness, and complainant's counsel instructs the witness that the meaning of the specification and claim of the patent must be ascertained by the instrument itself, and in view of the answers already given, complainant's counsel instructs the witness not to answer further to the question, and submits to the court whether the question is a proper one, and whether the witness must answer further.

(Question reread to witness, and under instruction of counsel witness declines to answer.)

Counsel for defendant here give notice that they will at the proper time move to strike out the entire deposition of the witness, for his refusal to answer the question, and will remove for
1222 such further relief as may be proper. Counsel for defendant, without waiving, but insisting upon his right under the above notice, continues the examination *de bene esse*.

X Q. 704. When answering question 23 of your examination-in-chief, what did you consider the invention or improvement covered by the 2d claim of the patent to be?

Objected to as incompetent and immaterial and as calling for a construction of the patent.

A. The invention stated by the 2d claim of the patent, upon a fair and reasonable construction of its words, and with reference to the other matter contained in the patent, not by forced construction, nor in a manner in which it might be said that the millen-ium had come, because the lion sometimes lies down with the lamb inside of him, but by taking the words in their ordinary signification.

Answer objected to as irresponsive.

X Q. 705. Question repeated.

Same objections.

A. The invention just as stated by the claim.

X Q. 706. Question repeated.

Same objections.

A. The combination substantially (as hereinbefore set forth, to wit, in the specification of the patent) of an electric circuit and an incandescent conductor of carbonized fibrous material included in and forming part of said circuit, and a transparent, hermetically sealed chamber in which the conductor is enclosed.

X Q. 707. Did you regard, at the time of making the answer referred to, that the shape of the conductor was a feature of the invention of this claim?

Defendant's counsel request that the counsel for complainant, if he has any objection to the question to make, that he will do so out of the hearing of the witness, as counsel desire witness to answer the question without any suggestion as to how he shall 1223 answer it conveyed in the form of an objection. This request does not apply to a simple request to the witness to decline to answer the question.

Counsel for complainant nevertheless, objects to the question in the presence of the witness *is* clearly improper, in that it calls upon the witness to state what he thinks the claim means in language other than that of the specification and claims, which counsel for complainant insists *that* the witness shall not do, being one of the inventors, unless he is instructed to do so by the court, and instructs the witness accordingly.

A. Inasmuch as the specification of the patent refers to the shapes and shaping of the carbons, and the material of which they were made before carbonization, and we did so make the carbons in shape, and the material before carbonization, and used material already shaped and selected, and to size, at least in one direction before carbonization, at the time I have stated in answer to the question you refer to, to wit, in the spring of 1878; if the court should hold that the 2d claim of the patent included the shape of carbon, my answer would also include in its consideration the shape of the carbon, as I took into consideration and had in mind in making that answer the words of the claim and the specification.

Answer objected to as irresponsive.

X Q. 708. Question repeated.

Same objections.

A. No further than I have stated.

Answer objected to as irresponsive.

X Q. 709. Question repeated.

Same objections.

A. I have no further answer to make.

Same objection to answer.

X Q. 710. Question repeated.

Same objections.

1224 Counsel for defendant desires to state upon the record that he has repeatedly requested counsel for complainant not to indulge in conversation with the witness in regard to questions and the answers to be made thereto, off the record, and now repeats the request on the record, that any remarks or suggestions that counsel for complainant has to make be made upon the record, and that they be read to the witness by the examiner, and counsel requests the examiner from this point on, to state on the record all that occurs at the hearing.

In response, complainant's counsel instructs the witness not to testify that he understands the claims to mean anything beyond or different from what is stated in the language of the claims, or that he regards anything as a part, or the invention described in the claims that is not stated in the description of the invention given by the claims, and calls the witness' attention to the fact that the claim in question does not call for any special form of incandescing conductor, but submits to the court whether the witness must answer the question and testify as to his understanding of the claim.

Counsel for defendant gives notice that, owing to the instruction just given by counsel to the witness, he will move to strike out the entire deposition at the proper time.

Witness says to complainant's counsel: "Do you mean by that to instruct me not to answer?"

Counsel says: "I mean by that to instruct you not to testify that you regarded the invention of the claim in question to be different from that described by the claim."

A. I have not so testified nor intended to do so, but inasmuch as an incandescing conductor must have a shape, I do not see how, without confining myself to any shape, I could regard in any way a combination, such, for instance, as is claimed in this claim without a conductor having some shape. I have not testified, 1225 nor do I intend to do so, nor to express the opinion that the court would hold that this claim had reference to any particular shape, or that I had in mind any particular shape when I answered the direct question referred to, but only that I had in mind the whole subject-matter of the patent.

Answer objected to as irresponsive and argumentative.

X Q. 711. Question repeated.

Same objections and instructions.

A. I don't understand the question. The claim itself, without reference to any of the rest of the patent, says nothing about shape, but is a combination claim of different things, in which shape is not included. I have already stated what I took into consideration, to wit: the exact words of the claim. Shape must be a feature of any incandescing conductor. The combination of the claim includes "an incandescing conductor of carbonized, fibrous material." How can it be considered without taking into consideration shape of some kind, or the shaping of it, which includes shape, I cannot see. So far I must have taken it into consideration and regarded it as a part of the claim. If you desire to know whether I took any particular shape of conductor into consideration or regarded it as part of the claim, I answer, I don't see how I could.

Answer objected to as irresponsive and argumentative.

X Q. 712. You would have saved much time if you had stated originally that you did not understand my question. Please tell me whether, at the time of answering question 23, you considered that the invention or improvement covered by the second claim of the patent, covered any specific form, or every form, of incandescing conductor made of fibrous material and placed in combination with other elements of the claim.

1226 Objected to as immaterial and incompetent, and as asking the witness now, whether at the time he answered the question-in-chief, referred to by counsel, whether he understood the claim to embrace something in addition to what is described by the claim.

A. I do not see how I could have done so when the claim makes no reference to form, and follows one in which form is referred to. I do not think I did, further than I have heretofore explained.

Answer objected to as irresponsive and argumentative.

X Q. 713. I am not concerned in what you "could" have done, or what you "think" your understanding was; please tell me —, in answering question 23, you considered the invention of the second claim to embrace, or cover, any specific form of conductor, or every form?

Objected to as incompetent, immaterial and irrelevant.

A. In answering your question I have already stated that I did not take into consideration in my answer to that question, form in any particular specific, or every form, further than I have stated, that every conductor must have form, as I think, and when I say, "I think," it is the conclusion that my mind is logically led to from the facts and circumstances, and for some slight consideration for my own intelligence.

Answer objected to as irresponsive and argumentative.

Question repeated and defendant's counsel requests the witness not to argue, but to answer his question.

Same objections and also that the witness has already answered the question very fully.

A. You have exhausted my recollection upon the subject; I have answered as fully as I can.

X Q. 714. Can you not state in terms whether, when answering
question 23, you did not or did consider the in*in*vention of
1227 the second claim of the patent in suit as covering every form
of conductor made of fibrous material, and placed in the combination stated, or only some specific form?

Same objections and as already fully answered.

A. I have already stated, and I repeat that in answering that question, I have no recollection of taking any specific form into consideration but only form generally. From the facts and circumstances, I think, and am confident that I treated the claim as stating only general form and not specific. By "general form" I mean any form applicable and suitable to an incandescent conductor for an electric light.

X Q. 715. Did this require on your part a construction of the claim?

Same objections and as not having any meaning.

A. I do not think it did, further than as any ordinary language must be construed to be understood.

X Q. 716. When answering question 23, did you consider that the cutting the conductor of that claim to size, prior to carbonization, was a feature of the invention, or improvement covered by that claim?

Objected to as incompetent and immaterial.

A. I don't think I considered it one way or the other.

X Q. 717. Have you no recollection as to whether you did or did not consider this question?

Same objections.

A. I have no recollection of having considered it.

X Q. 718. Then, do you mean that, as far as your recollection goes, you did not consider this subject?

Same objections.

A. I mean what I say.

X Q. 719. I understand you to say that you have no recollection of having considered it. Is my understanding correct?

Same objections.

A. It is.

1228 X Q. 720. It would seem to me to result from its not occurring to you whether the conductor of the claim must be cut to size prior to carbonization, that you must have considered that the invention of the claim covered any conductor of fibrous material, placed in the combination of the claim whether cut to size prior to carbonization or not. Do you wish to be so understood?

Same objections.

A. I have no objection to your having any opinion you may desire in the matter. I do not endorse your opinion or the contrary, and I am not concerned as to whether you are right or wrong in your conclusions as to what I had in mind, and do not wish to express an opinion.

Answer objected to as irresponsive.

X Q. 721. You seem to forget that this is a judicial examination, and that you are a witness testifying before a court of justice. You may be indifferent as to whether I do or do not understand what you mean by your answers; the court, however, is entitled to have clearly upon the record what you mean, and my effort, as an officer of the court, is to understand your testimony, so that I may not misquote you or mislead the court by any statement of mine in regard to your meaning hereafter. You have testified in this case that you were an attorney and counsellor at law, I will therefore not discuss with you the propriety of your last answer, and I have made this statement preparatory to my question to recall to your mind where you are. I repeat my question.

Same objections, and further objection that the question and a number of the immediately preceding questions are merely an attempt to obtain indirectly from the witness a construction of the patent. As to the lecture of defendant's counsel to the witness, complainant's counsel submits that it is a mere piece of impertinence. Neither the court nor counsel can have any difficulty in understanding the testimony of the witness nor the position of the witness as such. Counsel again instructs the witness 1229 not to testify to anything that can be considered as a construction of the claim or the patent.

A. I have not forgotten my position as a witness nor my duty to the profession of which I am a member, and I do not need a lecture upon that subject. If you quote my language, as I give it, you will not misconstrue my testimony to the court, and I have no fear but that the court will fully understand me and my testimony, but if you undertake to group together, according to your own fashion, and to give your own construction of my testimony for your own purposes, I shall hereafter, as in the past, tell you, in substance, that I am testifying and not you, and that I prefer to give that shade of expression and meaning to my words and plainly indicate it, which I prefer, and not to adopt or concern myself with your interpretation: I have answered your question and I am ready to answer any further questions. I repeat again, that whether your conclusion is right or wrong does not concern me. I have stated the facts.

Answer objected to as irresponsive.

X Q. 722. Question 720 repeated?

A. I do not wish to be so understood nor to be understood to the contrary effect. I wish to be understood as I said, that I do not recollect.

X Q. 723. You say that when answering question twenty-three you have no recollection of having considered whether cutting the conductor of *of* that claim to size prior to carbonization was a feature of the invention or improvement covered by that claim. Now, did you consider that the invention of that claim covered any incandescent conductor of fibrous material placed in the combination of that claim, whether cut to size prior to carbonization or not?

Same objections.

1230 A. The question asked me in question twenty-three was a question of time of invention. The invention of cutting the carbon to shape before carbonization, if it may be called such, and the matters mentioned in the combinations of claim two, were both discovered in the spring of 1878, and put in use by Mr. Sawyer and myself at that time. I did not understand myself as called upon by question twenty-three to give legal construction to that claim, but only to state when the invention stated in that claim was made. It was a matter of indifference, therefore, to me, in answering that question, whether it included carbon cut to shape or not, or involved carbon cut to shape or not. I could, therefore, and did answer the question by giving the time of the invention stated in claim two, without considering the separate parts of the invention, and without considering all that might be included in the claim by legal construction, or whether it was included in the claim by legal construction, and I made no attempt to give the legal construction to the claim further than to take the things there stated as facts. It was not necessary for me to consider in answering question twenty-three, whether the "invention" of that claim covered any incandescent conductor of "fibrous material placed in the combination of that claim, whether cut to size prior to carbonization or not," and I have no recollection of giving it consideration.

All that part of the answer of the witness prior to "it was not necessary," is objected to as irresponsive, argumentative and as many conclusions of fact, improper as evidence, the facts on which the conclusions are based not having been given, and the witness not having been interrogated in relation thereto.

X Q. 724. I understand from the latter part of your answer that when answering question twenty-three you do not recollect having considered the question whether the invention of the second 1231 claim covered any incandescent conductor of fibrous material, whether cut to size prior to carbonization or not. Do I correctly understand you?

Same objections.

A. I have no doubt that you correctly understand me, but my answer must be taken as a whole, including the reason I gave of concurrent invention doing away with the necessity of any such consideration.

All that part of the witness' answer following "but my answer" is objected to as being irresponsive and argumentative.

Witness here says that he wishes to have the first sentence of his answer read as follows:

"I have no doubt that you correctly understand me and the whole of my answer, but my answer must be taken as a whole, etc."

X Q. 725. Do you wish the court to understand your answer according to my statement in question 724?

A. Yes, with the explanation that I have given.

Adjourned till Friday, the 22d inst.; at 1 p. m.

FRIDAY, *July* 22, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. Man was continued as follows:

X Q. 726. When answering question 24, what did you understand the invention or improvement covered by the third claim of the patent to be?

Objected to as incompetent and immaterial, as the patent itself is the best and only evidence to prove what the invention of the claim is.

A. The invention stated in the 3d claim to wit, "the incandescent conductor for an electric lamp formed of carbonized paper, substantially as described," that is, as described in the specification preceding the claims in the patent.

1232 X Q. 727. What meaning did you attach to the words "substantially as described" when answering the question referred to?

Same objections.

Counsel for complainant withdraws his instruction given to the witness yesterday leaving the witness free to testify as he chooses, as to his understanding of the specification and claims of the patent in suit, but insists upon his objection as to the competency and materiality of such testimony.

Counsel for defendant inquires whether the withdrawal of the instruction to witness not to answer the questions submitted as to his understanding of the claims, applies to the instructions given at the last two sittings.

Counsel answers "yes."

Counsel for defendant waives for the present an answer to the question last submitted to the witness, as in view of the withdrawal of counsel from his previous position he desires to interrogate the witness further concerning his understanding of the invention of the 1st and 2d claims of the patent in suit at the time of testifying, on his direct examination.

Counsel for complainant desires it distinctly understood that he does not withdraw any of the objections, but only the instruction to the witness.

X Q. 728. I now repeat in substance cross-question 701 as follows: "Please state whether you considered at the time of answering question 7, cutting the material to size before carbonization as a feature of the invention of 1st claim?"

Question objected to on the ground that it is incompetent and immaterial in that it calls upon the witness for a construction of the claim of the patent to which the witness is not competent to testify, being one of the inventors to whom the patent was 1233 granted, and also as not proper cross-examination, and notice of motion is given that at the proper time counsel will move to strike out the question and answer.

A. The question 7 is a question simply, as I understand it, of time, to wit, the time when an invention stated in the claim, if any were stated, was made. In answering that question I read the claim and noticed its words. Inasmuch as it contained the words "as hereinbefore set forth," viz., as set forth in the specification of the patent, and the specification of the patent make reference to cutting the conductor to shape before carbonization, and the conductor was so cut to shape before carbonization by us and put to use at the time mentioned in my answer, to wit, in the spring of 1878, I think and believe that I had that fact in mind at the time of making answer to the question; I do not think that I considered at the time the abstract question, which I believe to be one of construction for the court, whether or not the cutting of the conductor to size and shape, or the shaping of it before carbonization, was covered by the claim; I have no recollection of considering any such question, and do not believe that I did.

Answer objected to as irresponsive and argumentative in stating conclusions of fact and not any facts concerning which the witness has been interrogated.

X Q. 729. Do you mean to be understood by your last answer that when answering question 7 you did not consider the question whether cutting the carbon to size prior to carbonization was, or was not, part of the invention of that claim?

Same objection and notice.

A. I mean simply that I do not recollect whether or not in my own mind at the time I decided or believed that it was covered by the claim or not. I do recollect that the fact of doing the thing, to wit, the cutting to shape before carbonization, was present to my mind in answering the question.

1234 Last sentence of the answer objected to as irresponsive.

X Q. 730. Before, and at or about the time of giving your examination-in-chief, had you advised or consulted with complainant's counsel in regard to the general subject of your testimony?

A. I had talked over the whole subject-matter of the patent with the counsel for complainant for the purpose of refreshing my recollection of facts, and informing him of what I did recollect.

X Q. 731. Was your examination furnished you for examination and correction by consent of counsel, prior to the beginning of the cross-examination?

A. The examination was conducted by question and answer, and subsequently was submitted to me after being written out, for examination and correction. I assumed that it was so done by stipulation of counsel.

X Q. 732. It strikes me as very peculiar that you cannot recollect whether, in answering question 7, in which you state that an invention was made at a certain time, the question not defining the invention or asking for any facts, but referring only to the invention as covered by the first claim of the patent, that you cannot now recollect whether you considered the invention to include or not to include this feature of cutting the material to size prior to carbonization. Is your failure to now recollect whether this question was or was not considered by you due to a defective memory?

Objected to on the ground that it does not fairly state the facts referred to, inasmuch as question 7 referred to a certain specific invention that is succinctly described by the claim itself, the claim of the patent, and that the inquiry of the question was limited to the invention described by the claim, and that there was nothing in the question to suggest to the witness' mind anything whatever about cutting the carbons to size before carbonization. 1235

A. In explanation of anything that may seem to you peculiar in the matter, I have already stated that the fact was present to my mind of cutting the carbon to shape before carbonization; that the time of the occurrence of that fact was concurrent with the other matters stated in the claim; that I did not and do not understand the question asked of me as calling for a construction of the claims; that the answer would be the same, whether I construed the claim to include the cutting of the carbon to shape before carbonization or not; that, therefore, I do not believe that I took into consideration the question whether or not it was included; and under those circumstances I cannot consider my failure to recollect whether I thought it was included or not included as due to a defective memory, as it was a matter of no consequence to my mind.

Same objection to answer as before.

X Q. 733. You were asked by question 7 when you made the invention covered by the first claim of the patent in suit, could you have answered that question without having some understanding in your own mind as to what that invention was?

A. No.

X Q. 734. Now, did you, when answering that question, have an understanding in your mind as to what the invention was?

A. I did.

X Q. 735. A clear understanding?

A. I believe so, as to the most of it.

X Q. 735*a*. If the first claim of the patent read: "An incandescing conductor for an electric lamp, of carbonized fibrous or textile material, and of an arch or horseshoe shape, cut to size prior to carbonization," would you regard the invention of the claim 1236 as the same as if the claim read "an incandescing conductor for an electric lamp of carbonized, fibrous or textile material and of an arch or horseshoe shape," assuming that in the latter case there was no mention in the specification of cutting the material to size before carbonization?

Objected to as incompetent and immaterial, and as calling upon the witness for his opinion on hypothetical claims not found in the patent and as unfair to the witness.

A. The claims would not be the same, and one would describe an invention not mentioned in the other.

X Q. 736. Should you, in the case supposed, regard the inventions as different?

Same objections.

A. Only in the respect that one includes an invention not mentioned in the other. In that respect, yes.

X Q. 737. You say when answering question 7, you did have an understanding as to what the invention of the first claim of the patent in suit was. Please state what you then understood it to be, and in this connection I request that you do not read the language of the claim as an answer, but state in your own language what you then considered the invention to be?

Objected to as incompetent and immaterial, and notice of motion is given to strike it out at the proper time.

A. I understood the invention to be the finding of an incandescing conductor for an electric lamp of carbonized, fibrous or textile material of an arch or horseshoe form, and therefore, as including as one kind of such conductor, one cut to shape before carbonization. Whether limited to or covering only one, cut to shape before carbonization, I do not think I determined in my own mind, not considering it necessary to do so.

X Q. 738. Is this what you mean: That you then considered the invention to be an incandescing conductor of fibrous or tex- 1237 tile material, and of the arch or horseshoe shape, and that you then considered and now consider that such being the invention, it would include such a conductor cut to size prior to carbonization as well as one not cut to size?

Same objection and notice.

A. Yes, I meant that and more.

X Q. 739. What do you mean by "more?"

Same objection and notice.

A. I mean that the invention might include the cutting to shape before carbonization, or that it might not include the cutting to shape before carbonization.

Answer objected to as argumentative, and as not stating any fact or recollection of the witness.

(Witness continues.) I had this in mind in answering question 7, to wit: The fact of the cutting to shape before carbonization, but not the determining whether such cutting to shape was included in the invention of the claim. I was answering as to time, and it made no difference in my answer whether the cutting to shape before carbonization was a part of the invention stated in the claim or not. If it was part of the invention stated in the claim, which I did not determine, my answer would be as given, in the spring of 1878. If it was not part of the invention stated in the claim, my answer would be the same.

Supplemental answer of the witness objected to as irresponsive and argumentative, and as stating conclusions of fact and not anything as to which he has been interrogated.

X Q. 740. Do you recognize that if the cutting the carbon to size before carbonization is an element of the 1st claim, the invention is different than if that element is not included?

Same objections and notice.

A. I recognize that the claim includes the conductor cut to shape before carbonization. I recognize also that there would be difference of invention if the claim were limited by cutting the
1238 conductor to shape before carbonization, or if the cutting to shape before carbonization were an additional element of invention stated or implied in the claim a difference from what the invention would be if the claim were not limited by the cutting to shape before carbonization, or if the cutting to shape before carbonization were not an element of additional invention stated or implied in the claim.

X Q. 741. Do you recognize this as true, that if the invention of the claim does not include as an element, this cutting to size, the claim is broader than if the element referred to is an element of the claim, the broader construction would comprehend the case of a conductor cut to size, whereas, if the cutting to size should be regarded as a necessary element of the claim, the claim would be narrowed and require for its infringement the infringing conductor to be so cut to size?

Same objection and notice.

A. I understand that if the claim were limited to a conductor; cut to size before carbonization, either by the terms of the claim or by construction, it would be narrower than if not so limited, and that there could be no infringement outside the limit of the claim.

Adjourned till Saturday, the 23d, 1887.

SATURDAY, *July 23d*, 1887.

Met, pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 742. You have stated that you assisted in the preparation of this claim, which invention did you intend to claim to cover, the broad invention of an incandescing conductor of fibrous material and of the arch or horseshoe shape, or the narrower invention of an incandescing conductor of carbonized, fibrous or textile material, and cut to shape prior to carbonization. 1239

Same objections and notice.

A. I intended that it should cover the broad invention including the fact that it was cut to shape or not cut to shape as the case might be. I did not know or contemplate whether the claim or invention would be subsequently limited to the narrower invention by construction or by the facts of the state of the art, or would not.

X Q. 743. If a block or irregular mass of textile or carbonized material should be taken and carbonized, and an arched or horseshoe-shaped conductor should be cut from such mass after carbonization, would such a conductor, according to what you intended the claim should cover, be within the invention of the claim?

Same objection and notice.

A. It clearly would be within the invention of the claim, if the mass which should be carbonized should be of selected, prepared and homogen-ous material of proper purity and suitably carbonized, such as described in this patent, but whether any conductor cut after carbonization from an indiscriminate mass of such material not homogen-ous, or pure, nor selected, would be covered by the claim in question, upon construction by the court, or under the facts in regard to the state of the art at the time when the invention was made, I do not know, nor do I recollect any question in my mind in regard to the matter at the time of the preparation of the claim.

X Q. 744. Do you mean to be understood from your last answer that a conductor of the kind specified in my question, would be within the invention you intended to cover by the first claim?

A. I mean that in my judgment it might be, if of the material described in the specification, and carbonized as therein referred to.

1240 X Q. 745. You say it might be; might such a conductor not be?

Same objection and notice.

A. That question is one that I cannot determine. The range of the future is illimitable. It seems to me probable, or at least possible, that it might not be, but I am unable to determine the question definitely.

Adjourned till Monday, the 25th inst., at 11 a m.

NEW YORK, *July* 25, 1887.

Met. Present, counsel as before, and the cross-examination of Mr. MAN was continued:

X Q. 746. At the time of filing the application for the patent in suit, did you consider the cutting the material to size prior to carbonization as necessary to the production of a suitable incandescent conductor for an electric lamp made of carbonized, fibrous or textile material?

Same objections and notice.

A. I considered it highly advantageous that the conductor should be either cut to size and shape before carbonization or made from materials already in shape, or that could be put in shape without cutting, in order to obtain the best conductor. I do not think that I considered it absolutely indispensable, though it was the method practiced by us, except in a few cases. In some cases we did select material already in shape and of the desired size, or which could be put in shape by a simple bending, and made a large number of conductors of such material, carefully selected, which were of as good quality as those that were cut to shape, and we also cut to shape after carbonization some conductors which were good; so that I cannot say that I considered it absolutely necessary that the conductors should be cut to shape before carbonization. I considered it highly advantageous.

1241 All that portion of the witness' answer which relates to what was done by them, objected to as irresponsive.

X Q. 747. Did you consider it necessary that the material should be either cut to shape prior carbonization or that the material to be carbonized should be of the same dimensions as the conductor to be made from it, or that the material should be carbonized in a sheet and the conductor cut from it?

Same objection and notice.

A. I did not consider it absolutely necessary that the material should be cut to shape before carbonization, or that it should already be of the size proper to make the required conductor after carbonization, or that it should be carbonized in a sheet of the proper thickness in order that it might be cut out of the sheet of carbon as formed, but I considered that this was the best and most practical way, but not an absolute necessity if the material were of the proper kind and properly selected before carbonization.

X Q. 748. If the material were of the proper kind and properly selected, could you obtain an incandescent conductor having the valuable properties of the fibrous conductor you assert to have been invented and used by Sawyer and Man?

Same objection and notice.

A. Yes; if it was of the proper size, such a conductor with proper selection of material, and of a mass of material rendered homogeneous beforehand and carbonized in mass with the utmost care and particularity, from a mass not too large, could be made, and was made by us having many of the properties enumerated in the specifications of the patent, but only with the utmost painstaking and care and by the highest skill of manipulation, and working with immensely a greater number of failures than successes; and we did not consider it a practical way of doing it.

1242 X Q. 749. Do you assert that an incandescent conductor of fibrous or textile material, and having the properties which you claim the fibrous conductor to have been invented by Sawyer & Man possessed, was ever made by you where the material had neither been cut to size prior to carbonization nor where the material when carbonized was substantially the size of the conductor, nor where the material was carbonized in a sheet of substantially the thickness of one of the dimensions of the conductor, and the conductor cut from this carbonized sheet?

Objected to as incompetent and immaterial, and notice of motion to strike out question and answer.

A. Yes. I think and believe that we made a conductor out of carbon of such material, selected and homogenized before carbonization, and cut to shape after carbonization, having most, if not all, of the properties mentioned in the specifications of this patent, but it was not a practical way of doing it, was very expensive and uncertain.

X Q. 750. Please state in what way the incandescent conductor to which you refer in your last answer as not being made by one of the methods described in my question 749, was made?

Same objection, same notice.

A. We used selected and compressed papier-mache, thick sheets of paper cemented or glued together, carbonized them in the usual manner in a furnace excluded from the atmosphere by powdered carbon. We took the masses in this manner, cemented them to laps or glass, worked them down to near the thickness required, cut them out in the other direction—in the direction parallel with the plate, with knives and gravers and files and emery—released them from the lap or glass, dried them, cemented them the other side up to the glass or lap, finished the surface that had been next to the glass or lap, released them from the glass or lap, when they were ready to be placed in the lamps. We also cemented masses of carbon, not of the shape or size of conductor required, after
1243 smoothing it off on one side to the flat end of a tool, put the tool with the carbon so cemented to it in lathe; turned out the inner portion of the carbon down to the tool, and the outside of the carbon to make a proper ring in the direction toward the centre, of a thickness corresponding to the conductor we wanted. Released

the carbon ring thus made from the tool, recemented it to the end of the tool the other side out; finished the outside; released the ring thus formed of carbon from the tool, placed it in the clamps of the lamp, and broke or cut away that part of the ring at the lower edge between the clamps, leaving the portion of the ring extending above the clamps, as the incandescent conductor of the lamp.

X Q. 751. Did you consider any of the methods referred to in your last answer practical?

Same objection, same notice.

A. They could be done; they were not practical in any commercial sense. I do not know whether they could be rendered so or not.

X Q. 752. Did any of the conductors——

Witness adds to his answer: "In speaking of the practicability, I refer to the making, and not the quality of the carbon; they were good carbons."

made by the method described in your 750th answer possess the properties you allege to be possessed by fibrous conductor, you claim to have been used and invented by Sawyer and Man?

Same objection, same notice.

A. Yes.

X Q. 752*a*. Were they as good conductors, or did you consider them as good conductors as those made the other way?

A. I do not remember to have compared them as to which was the best.

1244 X Q. 753. What was the object of either cutting the carbon to size prior to carbonization, or having the material to be carbonized of substantially the size of the conductor, or of carbonizing the materials in sheets of the thickness of one of the dimensions of the conductor?

A. First. The greater facility of shaping and sizing before carbonization over the facility of shaping and sizing after carbonization.

Second. The greater uniformity and facility of carbonization without fracture.

Third. Greater facility of tempering and consolidation in carbonizing.

Fourth. The advantage of nicer selection of material to be carbonized.

Fifth. Ability to obtain homogeneous material in the same conductor; and,

Sixth. The carbon made from material cut to size before carbonization is more uniform after carbonization, and smoother than it can be made after carbonization, more equal throughout in its electrical resistance or conductibility.

Adjourned to July 26th, 1887.

NEW YORK, *July 26th*, 1887.

Met. Present, counsel as before, and cross-examination of Mr. MAN proceeded:

X Q. 754. Are the second and third advantages pointed out in your 751st answer, due to the superior carbonization to be obtained by carbonizing a small mass of material over what would be obtained by carbonizing a larger mass?

Same objection and notice.

A. The second advantage which I have mentioned—avoidance of fracture and uniformity of carbonization without fracture—1245 has reference to the difference of strain in the material carbonized by the shrinkage which takes place in all carbonization. This liability to fracture is lessened by lessening the mass to be carbonized, so that the carbonization takes place more uniformly throughout it and the shrinkage goes on uniformly with the carbonization, avoiding fracture, while in the mass not cut to shape the carbonization does not proceed equally throughout the mass; the shrinkage is unequal in different parts of the mass, and the liability to fracture is increased. The third has reference to better carbonization, and more practical, of a mass already in shape over an amorphous mass shrinkage, consolidation, hardness, tempering, the same difference in kind which takes place practically in uniformly tempering a large mass of steel, as compared with the tempering of a small mass, or one formed to the shape desired before tempering.

X Q. 755. Which of the incandescent conductors made by Sawyer & Man did you consider the best adapted for the incandescent conductor of your electric lamp?

Same objection and notice.

A. Those formed to shape and size before carbonization, or those which were, before carbonization, already of the shape and size desired, according to my present opinion.

X Q. 756. Has your opinion changed any since the application for the patent in suit was filed?

Same objections and notice.

A. As I said yesterday, in answer to your question, I do not recollect having compared in my mind at the time the absolute quality of the few carbons, comparatively, which we cut out of the mass after carbonization with the quality of the many shaped before carbonization, or selected to size before carbonization, as the practical carbon for an electric lamp. I thought then, and still think, that the one formed to shape, or selected of the size and shape desired before carbonization, was the best by reason of the very ex-1246 treme difficulty of getting a good carbon by cutting to shape after carbonization.

X Q. 757. Did you regard the incandescent conductor made from carbonized fibrous material as superior to a conductor made from non-fibrous material?

Same objections and notice.

A. For many purposes, yes, and, on the whole, yes.

X Q. 758. Did you consider that you were the first persons to use carbonized fibrous material as the incandescent conductor for an electric lamp?

Same objections and notice.

A. We considered and believed that we were the first to make and use a good, practical incandescent conductor of an electric lamp of carbonized, fibrous or textile material, and we did not know, nor believe, then, nor do I know, nor believe, now, that any one, prior to us, had made or used a good, practical conductor for an incandescent lamp made from textile or fibrous material prior to the time when we made it, and I certainly did not know that any one prior to us had attempted to use, as the conductor of an incandescent electric lamp, carbonized, fibrous or textile material prior to our doing so, nor do I know it now.

X Q. 759. Did you know at the time of the application for the patent in suit that charcoal had been used as the incandescent conductor for an electric lamp, or that there were patents in which it was stated that the incandescent conductor of these lamps was made of charcoal?

Same objections and notice.

A. I knew of no such patents, and I do not think that I knew or had heard of the use of charcoal for this purpose, or that charcoal had been so used, except that I had heard at the time of, or prior to the application for this patent that Mr. Edison had tried to 1247 make such a conductor, late in the fall of 1879, from carbonized paper, and I knew of our own use prior to then.

X Q. 760. Do you now know that there were patents or publications prior to the 1st of March, 1878, in which incandescent electric lamps were described the conductors of which lamps were made of charcoal?

Same objection and notice.

A. I have heard such statements made; I do not know it as a fact.

X Q. 761. Did you, at the time of the application for the patent in suit, consider the arch or V-shaped carbon as original with Sawyer and Man, irrespective of the character of the carbon or the material?

Same objections and notice.

A. I did.

X Q. 762. What materials did Sawyer and Man try or use as the incandescent conductor for an electric lamp?

Same objection and notice.

A. Carbon, only of different kinds. I have very fully described, as I think, the different carbons we used. Carbons cut out of gas-retort carbons, carbons cut out of carbonized, fibrous and textile material, natural and artificial, carbons produced from such materials shaped and sized before carbonization and carbons made from such materials selected to shape and size before carbonization. French carbons prepared and sold in the market of what is usually known as mineral carbon, carbons made by ourselves from such material, usually called mineral carbons, carbons made by ourselves from various vegetable and animal substances not fibrous or textile; carbons made from lamp-black and bone-black with admixture of animal and vegetable substances, and not so mixed, carbons made by deposit by the use of an electrical current and a hydrocarbon gas or liquid. All the carbons I have enumerated treated after the manner of our patents for that purpose in a hydrocarbon 1248 gas or liquid, and the same not so treated. I do not now call to mind others, though perhaps there may have been others.

X Q. 763. Then, as I understand you, you tried and used the following classes of carbons for the incandescent conductors of your lamps: Non-fibrous, treated and untreated; fibrous, treated and untreated; and carbon obtained by electric action.

Same objection and notice.

A. Yes.

X Q. 764. And I understand of these classes you consider the fibrous carbon the best?

Same objection and notice.

A. I certainly considered the carbon obtained from fibrous or textile material the best. I considered that it was improved by treatment as a conductor for an incandescent electric lamp for general purposes.

X Q. 765. The patent in suit contains the following statement: "The advantages resulting from the manufacture of the carbon from vegetable, fibrous or textile material instead of mineral and a gas carbon are many." And then proceeds to point out such advantages. At the time the application for the patent in suit was filed was it, and has it always been your opinion, as stated in your last answer, that carbon from fibrous material was superior as an incandescent conductor to mineral or gas-retort carbon?

Same objection and notice.

A. At the time of the application for the patent such was my opinion according to my recollection. My first idea that it was superior was in the spring of 1878, when we first tried it. I do not think from my recollection now that my mind was fully made up in regard to the matter, except that it might be superior, and probably was, until on more extended trials of it, commencing the last of August or first of September, 1878, and continuing up to 1249 March, 1879. My mind was fully made up in regard to its superior quality early in October, 1878, perhaps in September. My mind was made up as to its excellence, whether superior or not, in the spring of 1878.

X Q. 766. Since the application for the patent in suit was filed have you changed your opinion?

Same objection and notice.

A. I do not think I have.

Adjourned till Wednesday, the 27th inst., at 10½ a. m.

New York, *July 27th*, 1887.

Met. Present, counsel as before and cross-examination of Mr. Man continued as follows:

X Q. 767. What did you consider the advantages of the arch or V-shaped conductor to be?

Same objections and notice.

A. First. The avoidance of shadows, except in the one direction, by placing both the attachments at the end of the conductors in the same plane so that the conductor would be entirely outside of that plane, and so that the shadow of the holders or support of the conductor would be cast in only one direction.

Second. By this form, doing away with the necessity of mechanical arrangements or appliances to compensate for or prevent the injurious effects of expansion or contraction of the conductor when heated up and cooled. In other words that the form permits the carbon conductor to expand and contract under the varying temperatures to which it is subjected, when the electric current is turned on or off, without the necessity of altering the position of its fixed terminals.

1250 X Q. 768. Aside from the advantage due to avoidance of shadows and the necessity of providing devices to compensate for the expansion and contraction of the conductor, are there any other advantages?

Same objection and notice.

A. Facility of manufacture perhaps. There may be other advantages. They do not occur to me now.

X Q. 769. What were the methods in practice before the spring of 1878, familiar to those skilled in the arts appertaining to the making of carbons for electric lighting, and what were the ordinary methods then in vogue of forming the material to be carbonized to the desired shape and size? I call your attention in this connection to that part of the specification of the patent in suit between lines 85 and 100.

Same objections and notice.

A. I do not remember to have seen, read or heard of any particular method prior to the spring of 1878, further than the ordinary method of carbonization, getting anything into shape and size and the ordinary method of carbonization, consisting of excluding the air from the substance to be carbonized and heating it up.

X Q. 770. The specification at the point noted, states:

"No special description of making the illuminating carbon conductors described in this specification, and making the subject-matter of this improvement is thought necessary, as any of the ordinary methods of forming the material to be carbonized to the desired shape and size, and carbonizing it while confined in retorts in powdered carbon substantially, according to the method in practice before the date of this improvement, may be adopted in the practice thereof by any one skilled in the art appertaining to the making of carbons for electric lighting."

Was it old in the arts at the alleged time of this invention to manufacture carbons by first forming the material into the
1251 shape and size which it was desired the carbon should be, and then to carbonize the material so formed, to shape or size?

Same objections and notice.

A. The making of anything to shape or size was not new at the time of our invention. The method of making anything almost to shape and size was well known and in ordinary use. The carbonizing of different substances had been long practiced previous to our invention. The methods of carbonization of different substances as an act of carbonization alone consisting of excluding air and applying heat were also, of course, well known. By this I do not mean that new methods and better appliances for the purpose might not have been the subject-matter of invention in the spring of 1878, but prior to that time I had never heard, read or seen the making of a carbon conductor for an incandescent electric light, a delicate, fragile and difficult article to produce, by first cutting the material to be carbonized on forming or selecting it to the appropriate size and shape, and then carbonizing it afterwards in shape and of the size appropriate to produce the article required. I think a carbon conductor of an incandescent lamp so produced, was new and a new article of manufacture in the spring of 1878, and I think, further, that Mr. Sawyer and myself were the first to realize and discover that by this method of procedure the incandescent conductor of an electric lamp could thus be practically produced, and so far as I know, in this manner only, be practically on a large scale, and that by following this method of procedure the conductor would possess, or could be made to possess, the properties essential to an incandescent conductor, as I believe, viz., purity and equality of the carbon, susceptibility to tempering, both as to hardness and resistance, and toughness and durability. I do not know whether other things had, prior to this time, been cut to shape or size and afterwards carbonized or not. I do not think that the incandescing con-
1252 ductor of an electric lamp had been so produced, and believe from all that I have read and heard of upon the subject that it had not, and I further feel confident that no one, prior to this time, had realized that by this method of procedure such a conductor would be produced, possessing the essential properties and requisites of the incandescing conductor of any electric lamp which I have enumerated.

Answer objected to as irresponsive and argumentative, and containing many conclusions of fact in regard to which witness has not been interrogated.

X Q. 771. Please state whether at the alleged time of the invention of the patent in suit, it was old in the arts where an article of carbon (I do not refer to the incandescent conductor of an electric lamp, but to any article of carbon) was desired to have a certain size and shape, to cut or form the material of which the carbon article was to be made to the desired form and size of such article, and carbonize it after being so cut or formed to size and shape.

Same objection and notice.

A. I do not remember now any article made from carbon that was at the time usually, or ever, so cut to shape or form before carbonization, but I do not know as a fact whether at that time it was old or new to do so.

X Q. 772. The specification of the patent as a reason for no special description of making the illuminating conductor of the patent, states that any of the ordinary methods of forming the material to be carbonized to the desired shape and size, and carbonizing it while confined in retorts and powdered carbon, substantially in accordance with the method in practice before the date of the improvement, may be adopted by any one skilled in the arts appertaining to the making of carbons for electric lighting or other purposes, you say that you considered the forming of an incandescent conductor to size and shape before carbonization as new with you, and that you do not know whether it was new or old to
1253 form articles of carbon to shape and size before carbonization
or not. Will you, therefore, explain what you meant by the statement in the patent, that any of the ordinary methods of forming the material to the desired size and shape should be followed, and what you meant by the further statement that these methods should be, substantially, according to the method and practice before the date of the improvement?

Same objection and notice.

A. I have already in my answer to question 770 endeavored to make such explanation. I will now repeat in substance my interpretation of the statement of the specification, to wit, that no special description of the making of the illuminating carbon conductors, consisting, first, in cutting to shape, and second, in carbonizing, was thought necessary, because cutting a thing to shape or forming it to shape and size, anything, was a common thing in the arts and any one skilled in the arts appertaining to the making of carbon for electric lighting, could make use of the means and methods (knowing the size and shape of the thing he was required to produce and its purpose) for making anything into shape and size.

Second, that no special description of carbonization was deemed necessary, as any one skilled in the art of making carbons for electric lighting, or for other use in the arts, could do the carbonizing in methods, substantially, according to the methods in practice for carbonization, before the date of our improvement, being skilled in the art, he would know how to do carbonizing. In other words, the two things required in the manufacture of carbon conductors for electric lamps, cutting to shape and carbonization, were both well-known operations, and could be practiced by any one skilled in such work.

X Q. 773. At the time of the alleged invention, was there, in fact, any art in existence appertaining to the making of carbons for electric lighting?

Same objections and notice.

1254 A. There was, for arc lighting; I knew of none for incandescent lighting further than the ordinary arts not specially applicable for making carbons for incandescent lighting, more than to other things. There was not at the time, so far as I knew, or have since learned, any manufacture going on except our own of carbons for incandescent electric lighting.

X Q. 774. Was there any art in existence appertaining to the making of carbons for electric lighting at this time, in which fibrous material that had been carbonized was used?

Same objection and notice.

A. I knew of none.

X Q. 775. Or in which the material was formed to size and then carbonized?

Same objections and notice.

A. I knew of none, or at least none occurs to me now, as known and practiced at the time.

X Q. 776. Was there at this time in existence any art in which carbon obtained from fibrous material was used?

Same objection and notice.

A. I think there was, but none in which the textile or fibrous structure was preserved in the carbon as put to use.

X Q. 777. What was the art to which you refer?

Same objection and notice.

A. Before this time, pencils or rods for arc lighting had been made by carbonizing such materials, grinding them up and forming them subsequently into the pencils.

X Q. 778. Any other art?

Same objection and notice.

A. Yes; carbon obtained from fibrous and textile material was used in many and perhaps most of the arts, directly or indirectly. It was used for filters, it was used for disinfection, it was used as a medicine, it was used by the blacksmiths. I could not go on to enumerate the very many uses to which carbon made from
1255 such material was put. If, however, your question refers simply to carbon made of such material in which the fibrous

or textile structure was preserved intentionally, or was an element of its usefulness, I do not recollect any.

X Q. 779. Was there, at this time, in existence any art in which carbonized fibrous or textile material was used where the material was carbonized while confined in retorts and surrounded with powdered carbon?

Same objection and notice.

A. Yes, I think there was.

X Q. 780. What art?

Same objection and notice.

A. The art of making carbons of charcoal for crayons and for rubbing down and polishing metals, especially the plates used in engravings.

X Q. 781. Any other?

Same objections and notice.

A. There may have been others, I don't recollect them.

X Q. 782. Were these crayons cut to size and shape before carbonization?

Same objection and notice.

A. No, not to my knowledge, I never heard of it.

X Q. 783. Is this a subject with which you are familiar or on which you are ignorant?

Same objections and notice.

A. A subject with which I was familiar prior to 1878.

X Q. 784. Do you know whether it was old in the arts prior to the alleged date of this invention, in making artists' and other crayons from fibrous material to the *material to the* desired shape and size and to carbonize it after being so shaped and cut?

Same objections and notice.

A. I do not know whether it was done or not. I only know
1256 I was never aware of any such thing. I had large occasion
to make use of such crayons and procured them in large
quantities that were not so produced.

X Q. 785. I understand that you were not aware that prior to the alleged date of this invention various articles had been made from carbonized fibrous material, in which the material had been cut to shape and size prior to carbonization and then carbonized.

Same objection and notice.

A. All I can say is, I do not now recollect any such article.

X Q. 786. But you do know it was old to carbonize fibrous or textile material while confined in retorts and surrounded with powdered carbon?

Same objections and notice.

A. Yes, I think it was.

X Q. 787. Were there at the alleged time of this invention, so far as your knowledge goes, any ordinary methods that were familiar to any art of first forming material to be carbonized to the desired shape and size and then carbonizing it while confined in retorts in powdered carbon?

Same objection and notice.

A. There were ordinary methods of forming material to shape and size and ordinary methods of carbonization; that there were any arts in which it was required to first form the material to shape and size and subsequently to carbonize the same, in which the two processes combined were essential or necessary to the product, I do not know; none occur to me now.

X Q. 788. When you say there were ordinary methods of forming material to shape and size, do you mean that there were a number of arts in which it was common to take fibrous material and cut it or form it into a desired shape and size such as the trade of the carpenter.

Same objections and notice.

1257 A. Yes, the trade of the carpenter, the Yankee whittler, and almost every trade and occupation.

X Q. 789. Now, there being, so far as your knowledge goes, no methods in practice before the date of this invention, of first cutting the material to size and shape and then carbonizing it, what was meant by saying that of these "ordinary method-, the method to be adopted must be substantially according to the method in practice before the date of this improvement."

Same objections and notice.

A. I do not understand that there is any statement in the patent that any method of cutting to shape or of carbonizing, or of first cutting to shape and then carbonizing, must be adopted (and the word "must" is not used) but only a reason given that it was deemed unnecessary to describe the manufacture of the carbon incandescent conductor of an electric lamp, for the reason that the steps of manufacture were known at the time of the invention; by this I do not mean to say that the order of procedure, first cutting to shape and size and subsequently carbonizing, is not pointed out and deemed an advantage; the words of the specification are:

"No especial description of making the illuminating conductor, etc., is thought necessary, as (or because) any of the ordinary methods of forming the material to the desired shape and size, and carbonizing it substantially according to methods in practice before the date of the invention might be adopted in the practice thereof, (to wit, in the making) by one skilled in the art," etc.

X Q. 790. You have said that you regarded yourselves as the first to make an incandescent conductor of carbonized fibrous material, that being so, were there at the time of this invention any ordinary methods known of forming the fibrous material to the desired shape and size?

Same objection and notice.

1258 A. I have said that I deemed we were the first to make a practical incandescent conductor for an electric lamp of carbonized fibrous or textile material, and I mean to say that there were ordinary methods applicable to this and a great many other things for cutting such material to shape and size before carbonization, not differing in character from the process of cutting the material to shape and size from which an incandescent conductor was to be produced.

X Q. 791. That may all be, but what I want to know is, whether there were at the time of this invention any ordinary methods then known of forming to shape and size for the special or particular purpose of an incandescent conductor of fibrous or textile material?

Same objection and notice.

A. There were well-known methods by which it could be done, and which would occur to any one of ordinary intelligence who should have occasion to do it; I do not mean to say or to be understood that it had actually been done, more than I would mean to say that there was a practice of cutting or a method of cutting or shaping some unknown thing just now found out, which was capable of being cut or formed to shape in the ordinary method of cutting or forming to shape anything else, almost, nor do I interpret the patent as saying any such ridiculous thing.

X Q. 792. Then you did not intend this as meaning anything more than that in forming the material to size and shape, a person following the patent should do it in such a way as seemed to him best.

Same objection and notice.

A. I have not indicated any such thing; I have said in substance, and repeat that my interpretation of that part of the specification to which you refer is, to point out the order of doing things and to state that it was unnecessary to describe cutting or forming to shape to such persons, to wit, those skilled in the art of making conductors for incandescent electric lamps, at the time when the application for the patent was filed, because at the time of the invention such a person by pursuing the order pointed out and using the means then known for forming and cutting to shape and the means then known for carbonization, could make such conductors. 1259

Answer objected to as irresponsive and argumentative.

X Q. 793. Question repeated.

Same objection and notice, and further on the ground that it is indefinite and misleading.

A. I now understand the question as asking me in regard to the step in the process of manufacturing or making a carbon for an incandescent lamp, implied in the words, "cutting to form or shape." I distinctly state, as the specification does, that I deemed it unnecessary to describe so simple a process, and I wish to be understood as saying that I believe any intelligent, skillful person would have no difficulty in the cutting or making to shape, no more nor no less.

X Q. 794. Do you regard that portion of the specification as a statement that a process consisting of two steps was to be followed—first, cutting the material to the desired shape, and, second, carbonizing it after being so cut?

Same objection and notice as last but one.

A. I regard it as a statement that it was unnecessary further to describe the making of the carbon, than is done in the specifications, and that it was a statement indicating that if the order therein pointed out, first, cutting to shape and then carbonizing, was followed, it would be all that was necessary in the hands of a skillful person.

Answer objected to as irresponsive.

X Q. 795. Question repeated.

Same objection and notice.

1260 A. The question being repeated I endeavor to answer responsively. I regard it as a statement pointing out the steps, which, if followed would result successfully.

X Q. 796. Do you regard those steps as being two; first, cutting the material to the desired size or shape; second, carbonizing it after being so cut?

Same objection and notice.

A. I do.

X Q. 797. Now, so far as the first step is concerned, do you regard this portion of the specification as meaning that the person following the patent is to cut the material to size and shape in such manner as he should think best?

Same objection and notice.

A. Yes, according to well-known methods of cutting or forming things to shape.

X Q. 798. But there were no well-known methods at the time of this invention of forming an incandescent conductor to shape?

Same objection and notice.

A. Yes, but only in the sense that there were no such conductors being made except by Sawyer & Man, and not in the sense in which there were well-known means by which it could be done.

X Q. 799. Then, when the specification says that any of the ordinary methods of forming the material to the desired shape and size may be employed, you did not intend it to mean that at the time of the invention there were ordinary methods known of making this specific article, but only intended it as meaning that, in forming the material to size, the person so doing should exercise his best judgment as to the way of doing it?

Same objections and notice.

A. No, we did not intend it to mean that there were ordinary methods of forming the material of an incandescent conductor to shape and size as a specific thing, at the date of the invention,
1261 but we meant that any of the ordinary methods of forming material to shape and size to be carbonized, or otherwise, substantially according to the methods in practice for forming and shaping any material before the date of the invention, might be adopted.

Adjourned till Thursday, the 28th inst., at 10.30 a. m.

THURSDAY, *July 28th*, 1887.

Met. Present—Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 800. "Methods in practice" in the ninety-fifth line of the specification according to your understanding of this clause, do not mean methods in practice before the date of the improvement of making illuminating conductors by cutting the material to size and then carbonizing it, but only mean methods in practice of cutting anything to a desired shape without reference to the fact that it is to be carbonized, and methods in practice for carbonizing things that could be carbonized?

Same objection and notice.

A. That is my interpretation of the meaning of the specification, and I do not think the specification contains an assertion, or is intended to do so, that there were methods in practice at the time of making the improvement, of cutting the material for an incandescent conductor to shape and size, and then carbonizing it.

X Q. 801. The suggestion being made that the material should be cut to size and then carbonized, did you consider that it would require invention to properly cut or shape the material and properly carbonize it?

Same objection and notice, and on the ground that the witness was not produced as an expert on the question inquired about.

1262 A. The act of so cutting, and the act of carbonizing alone, it does not seem to me could be the subject-matter of invention, but the adaptation of size and shape to the purpose would involve invention, as it seems to me, and the properties imparted to the conductor by carbonization, after sizing and shaping, would, it seems to me, be the subject-matter of invention, and the conductor produced with the particular qualities of such a made conductor, it seems to me would be the subject-matter of an invention, and properly patentable.

X Q. 802. As when the suggestion was made that the material should be cut to size and then carbonized, it would not, in your opinion, require invention to properly cut and carbonize the conductor, what art or class of artizans at the time of the invention, possessed the requisite skill and information to properly perform these two steps?

Same objections and notice as to last question but one.

A. Understanding your question to refer to the mere acts of cutting and carbonization, all arts involving delicate cutting and shaping and handling, such as the use of scissors, knives, punches and dies, fine small planes, guarded knives of the character of spoke-shaves, the use of fine emery papers for cutting. And for carbonizing, I think the manufacturers of crayons and manufacturers of bone black, the workers in chemicals and experimental laboratories. Probably there were other arts for both, but these now occur to me.

X Q. 803. Was there any one art or class of artizans possessed of the requisite skill to properly perform both steps at the time of the invention, if so, please state?

A. I remember none in which both steps were necessarily practiced at the time of the invention, but I think the intelligent conductors of chemical laboratories were capable of performing both.

1263 X Q. 804. In the year 1885 do you know whether arts had grown up and existed in which there were what might properly be described as ordinary methods forming to the desired shape and size of the incandescent conductor, fibrous material, and in which there were what might properly be described as ordinary methods of carbonizing such material?

Same objection and notice.

A. Yes, I think there were.

X Q. 805. Were there in 1885, methods in practice familiar to the art of incandescent lighting, of cutting fibrous material to size and shape and carbonizing it after so cut?

Same objection and notice.

A. Yes, I think so.

X Q. 806. Referring to the second claim of the patent in suit, did you regard "a transparent, hermetically sealed chamber" in which the conductor was to be inclosed, as original or new with Sawyer and Man?

Same objection and notice.

A. Only, I think, in the combination stated in the claim.

X Q. 807. Referring to the fourth claim of the patent did you consider "an illuminating chamber made wholly of glass, hermetically sealed and out of which all carbon-consuming gas has been exhausted or driven," as original or new with Sawyer and Man?

Same objection and notice.

A. In the combination stated in the claim, yes, in and of itself I don't know or remember.

X Q. 808. Did you consider as original and new with Sawyer and Man, the following element of the fourth claim, "an electric circuit conductor passing through the glass wall of said chamber, and hermetically sealed therein as described"?

Same objection and notice.

A. Yes, I believe I thought so at the time of the application for the patent.

1264 X Q. 809. Do you regard the patent as issued, as containing any different or other invention, or claiming any different or other invention than the application as originally filed?

Same objection and notice, and as calling for expert opinion.

A. In the sense that it claims less than the application as originally filed, claimed, yes; in any other sense I consider that all that is claimed in this patent and more, was in the specification and claims of application as first filed.

X Q. 810. At the time the application for the patent in suit was filed, did you consider that an arc of carbon, whether made from fibrous material for from gas-retort carbon as a conductor for an electric lamp, was the invention of Sawyer and Man, and as such patentable?

Same objection and notice, as to last question but one.

A. Yes, I knew that we invented it, believed that we were the first to invent it, that it was therefore patentable to us, and intended to claim it.

X Q. 811. Did you consider that you were the first to use mineral carbon of any form as the incandescent conductor?

Same objection and notice.

A. No.

X Q. 812. Then as to the first two claims of the application as originally filed, all that you considered as new was the arc or arc shape?

Same objection and notice.

A. That is all we intended to claim and as confined to carbon.

X Q. 813. Do you regard or did you at the time it was filed, regard the original application as in any way stating a preference of the carbon made from fibrous or textile material, over one made 1265 from metallic carbon, or as pointing out any advantages possessed by the one over the other?

Same objection and notice.

A. Yes.

X Q. 814. Please point out what, in your judgment in the original specification, indicates such a preference of the one over the other, or what advantage one is stated to possess over the other?

Same objection and notice.

A. Claim third is a claim for a combination, including a fibrous or textile material. Claim fourth is for the incandescent arc of carbonized fibrous or textile material. The specifications state the object to be, to secure a cheap and effective apparatus (the word "apparatus" evidently referring to the word "conductor" going immediately before it). Immediately following this statement in the specifications are the words, "The subject-matter claimed is hereafter specifically designated." I think no other construction can be put upon them than what I have put on them.

X Q. 815. Do you think, and did you think at the time it was filed, that the original specification indicated a preference of a conductor of fibrous carbon over one of metallic carbon?

Same objection and notice.

A. Yes.

X Q. 816. Now point out what, in the specification, you regard as indicating such a preference?

Same objection and notice.

A. Claim 3d and 4th, in connection with the words of the specification commencing on the first page with the words "our invention" and ending with the words "specifically designated," together with the whole scope of the specification and the statement of the kind of carbons we had used.

1266 X Q. 817. What is there between the words "our invention" and the words "specifically designated," which taken by itself, in your judgment, indicates such a preference?

Same objection and notice.

A. The statement that "the invention especially relates to the incandescent conductor," and that "its object is to secure a cheap and effective apparatus" (the word "apparatus" evidently referring to and used as synonymous with "conductor"), and the statement that "the subject-matter claimed is hereinafter specifically designated." That designation I take as referring to the claims, and it evidently is so. The third and fourth claims, therefore, are referred to between the words you named, and are to be taken as part of the meaning between those words.

X Q. 818. And the first and second claims also referred to, and are to be also taken as part of, the meaning of these words?

Same objection and notice.

A. They are, but they have no reference to the preference in regard to which you ask me.

X Q. 819. What do you regard in the statement, "we have tried carbonized paper covered with powdered plumbago, wood carbon or charcoal and ordinary gas carbon," as indicating a preference of carbon of fibrous origin over metallic carbon?

Same objection and notice.

A. Taken alone, without reference to anything else in the specifications or the claims, I do not know that they express a preference; but, taken in connection with the whole specification and claims, especially with the fact that textile and fibrous carbon is specifically claimed, while gas-retort or mineral carbon is not, they seem, to my mind, as aiding in indicating our preference as to carbon.

1267 X Q. 820. Now, point out what, in the original specification you regard as stating the advantages of carbon of fibrous origin to be.

Same objection and notice.

A. The only thing that I see in the specifications is the reference on page 1 stating the object of the invention to be to secure a cheap and effective conductor, with the reference made on the same page to the thing specifically claimed in the words, "The subject-matter claimed is hereinafter specifically described." These two things, to the mind of a person accustomed to make conductors for incandescent lamps would point out the advantage of cheapness of construction of a conductor of textile or fibrous material over conductors made of mineral or gas-retort carbon.

X Q. 821. You think, then, that the original specification points out, because it states "its object is to secure a cheap and effective apparatus" (by apparatus you understand a conductor to be meant), that persons skilled in making conductors for incandescent lamps would know that the fibrous carbon conductor is made more cheaply than the metallic carbon conductors?

Same objections and notice.

A. Yes, taken in connection with the third and fourth claims.

X Q. 822. Were there, at the alleged time of this invention, persons skilled in the making of conductors for incandescent lamps?

Same objection and notice.

A. At the time of the invention, I knew of none but ourselves, Sawyer and Man. At the time of the application there were such persons.

X Q. 823. Do you regard the original application as pointing out any advantage possessed by the conductor of fibrous carbon over the one of gas-retort carbon other than cheapness of making?

Same objection and notice.

1268 A. The words "pointing out" are perhaps too strong, and I should prefer to use the work "indicating." I think the advantage of "effectiveness" is indicated in connection with cheapness of construction, by specifically claiming the carbon made from fibrous or textile material, and indicating thereby a preference for that kind of material.

X Q. 824. Question repeated.

Same objection and notice.

A. Yes, I think the advantage of effectiveness is pointed out.

X Q. 825. Please state what you consider as pointing out the advantage of effectiveness.

Same objection and notice.

A. I think effectiveness for the carbon made of fibrous or textile material is pointed out by the fact that it is specifically claimed, and by the fact that the object of the invention is stated to be "to secure a cheap and effective apparatus," by which I understand to be meant conductor.

X Q. 826. Do you regard the original specification as stating in what this effectiveness consists?

Same objection and notice.

A. I do not know that it does.

X Q. 827. Had the patent been granted upon the day and in the form in which the application was originally filed, do you seriously mean to say that in your opinion this patent, so and then issued, would have indicated a preference for fibrous carbon over non-fibrous carbon, and would have indicated that the inventors considered the one superior to the other.

Same objection and notice.

A. Yes. Otherwise they would not have specifically claimed it.

X Q. 828. Do you on your oath now state that at the time you filed this application you considered a fibrous, superior to a non-fibrous carbon?

Same objection and notice.

1269 A. No. Not in exactly those terms. My mind was made up, as I have stated before, in the fall of 1878, from all that I knew in regard to the matter, that a carbon from fibrous or textile materials was better for the incandescent conductor of an incandescent lamp, than carbon made from gas-retort carbon, or from any other materials that we had used. I considered it the most valuable kind of carbon for the purpose. I was not at the time so fully advised as to decide whether the fibrous carbon was better than any other that had been, or should be made, that was not fibrous.

X Q. 829. I do not understand your answer. I want you to tell me now on your oath whether, at the time when this application was filed, you did or did not consider a carbon of fibrous origin superior to one of non-fibrous origin?

Same objection and notice.

A. I have already answered the question fully. I considered carbon made from fibrous or textile material most available, and better in that respect and in its qualities than any other carbon I knew of.

X Q. 830. Question repeated. And counsel states that he wishes a categorical answer, and requests counsel for complainant to instruct the witness to so answer his question.

Same objection. Counsel for complainant replies that the witness has already specifically and definitely answered counsel's question, and in view of that fact he declines to give the witness any instruction such as called for.

Counsel for defendant requests counsel for complainant to state whether he regards the witness as having answered question 829, yes or no.

Counsel replies that he undestands the answer of the witness to be in the affirmative as far as his then experience had enabled him to decide.

A. Yes, so far as I then knew. I have no recollection further, as I have stated before as my answer.

X Q. 831. Have you changed or altered your opinion since?

1270 Same objection and notice.

A. My opinion of that time has been brought in question to my mind several times since. It is now with me, with the further knowledge I have obtained, an undecided question whether carbon made from fibrous or textile material, or carbon made from material not textile or fibrous is the best, with a preference for that made from fibrous or textile material.

X Q. 832. I want to know whether since the application was filed, you have altered your opinion; I wish you to answer me yes or no.

Same objection and notice.

A. I have stated the facts in regard to my present opinion, and the fact in regard to my opinion at the time of the application for the patent, and the fact that at present I was unable to form a definite opinion, and I am unable therefore to answer directly yes or no.

X Q. 833. When, if at all, did you alter your opinion which you had at the time the application was filed that fibrous was superior to non-fibrous material?

Same objection and notice as last but one before.

A. I have not stated that I altered it.

X Q. 834. Have you since the application was filed altered your then opinion that fibrous was superior to non-fibrous material?

Same objection and notice.

Counsel for defendant asks counsel for complainant to instruct the witness to answer the question categorically.

Counsel for complainant understands from the witness' last answer that the question may not be properly susceptible of a categorical answer, but he instructs the witness to give a categorical answer if he can do so without misleading the court.

A. The trouble is that the counsel for defendant insists 1271 upon stating the opinion given by the witness differently from the statement of the witness as to his opinion at the time the application for the patent was made. My statement was that my opinion was at the time, that carbon made from fibrous or textile material was better than any other that I knew of. The question states that I had the opinion that carbon made from fibrous or textile material was better than carbon not made from fibrous or textile material, as I understand the question, my opinion being that it was better so far as I knew, but not an absolute opinion that it was positively better.

X Q. 835. Well, have you or have you not altered that opinion since?

Counsel for defendant requests a categorical answer. Objection and notice same as last.

A. I think I have, in the respect only, that I am not so confident that my opinion is right as I was at the time of the application for this patent.

X Q. 836. I do not understand your answer; do you know whether you have altered your opinion or not since the application was filed?

Same objection and notice, and on the further ground that the witness has very fully and specifically testified on this matter, and that the object of the question appears to be merely to anney and harass the witness.

A. My opinion is the same in kind now as then, less strong now than it was then, it is an alteration in opinion only as regards strength of opinion; so far as I know my opinion is altered.

X Q. 837. Do you mean that you have not altered your opinion, but that your opinion is not as strong now as then?

Same objection and notice as to question next before the last.

A. I mean that my opinion is not altered in kind, but is in strength.

1272 X Q. 838. I understand that you are of the same opinion but it is less strong?

Same objection and notice.

A. That very nearly expresses my opinion if you insist upon it; it is not a perfectly accurate statement.

X Q. 839. Have you ever testified under oath since this application was filed, that you preferred and always did prefer a carbon of non-fibrous origin to any other carbon used by Sawyer & Man?

Same objection and notice.

A. I do not remember to have ever done so.

X Q. 840. Do you think it possible that you could have done so and forgotten it?

Same objection and notice.

A. It does not seem to me so intentionally; my recollection of past events may have been different at some time from what it is now, and I may have given such recollection different from my present recollection, but I do not think it.

X Q. 841. I call your attention to the following answer and question given by you on April 15th, 1879, in the interference between Sawyer and Man, Kieth and Maxim. Q. "After the carbon has been heated as you describe, how does it compare in color and density with the same carbon and its utility as an electrode in electric lighting." A. "The original strip of carbon is deprived of its impurities which — driven off. The poles are filled with a dense deposit of pure carbon and its outside coated with the same; it appears more uniform and its outside has a bright silvery lustre, instead of being black; it is much stronger and less liable to fracture and almost indestruct*a*ble by combustion, uniting with very great difficulty, if at all, with any other substance under the influence of heat or electricity, and, therefore, a much better substance for the electrodes of incandescent parts of electric lights and the deposited carbon when separated from ths original pencil is a better article still for these purposes."

1273 —. Do you remember giving this testimony?

Same objection and notice.

A. Yes, I think that is correct.

X Q. 842. Is it true?

Same objection and notice.

A. Yes, in the sense and in the connection in which it was used there then.

X Q. 843. Did you then consider carbon deposited by electric action and cut so as to make an incandescent conductor, as a better article for the electrodes or incandescent parts of electric lights, than a slip of carbon upon which carbon had been deposited according to the Sawyer and Man process?

Same objection and notice.

A. Yes, intrinsically.

X Q. 844. How do you reconcile this testimony given in April, 1879, with your testimony in this suit?

Same objection and notice.

A. They are both perfectly reconcilable, and in the one case the question in my mind, and to which I made answer, was one in regard to the intrinsic character of carbon, in the other it is a question solely of the practicability and usefulness of an incandescent conductor and of its character; you have endeavored to force me to say that I considered carbon made from fibrous or textile material, aside from its practicability and facility for making and usefulness in incandescent electric lighting, superior to all other carbons; I have endeavored to keep out that exact statement and to state my own views in regard to it. A fair construction of my language, and the whole of my testimony, will not exclude the idea, nor have I intended to do so, that carbon deposited by electric action aside from the practicability of manufacture and only considering its intrinsic character, is the ideal carbon for the incandescent conductor of an electric lamp, and you will remember my statement while giving this testimony that I considered the carbon conductor made 1274 from fibrous or textile material to be improved by treatment after the manner referred to in my testimony to which you have called my attention. The difficulty is solely that you leave out of view the context of my statements and if in your bulldozing and insisting upon categorical answers, you have obtained anything from me that would imply that my statement in the testimony you have referred to is not true, I withdraw it, because it was my opinion then, and it is my opinion now, that the incandescent conductor of an electric lamp formed from carbonized fibrous or textile material and treated after the manner of our patents, all things considered, is the best conductor I know of, though in regard to the textile or fibrous carbon being the best substratum conductor, my opinion at the present time is not so strong as it was at the time of the application for this patent. By substratum, I mean, the form, shape, and size of the conductor for an incandescent lamp, having in mind its subsequent treatment after the patented processes of Sawyer & Man, and having in mind the facilities for obtaining such a conductor in proper size and shape, its cheapness of construction, its good qualities and availability. It is for such purposes the best carbon I know of, in my opinion. If, however, the same carbon could be cheaply obtained, put in size and shape reduced to size and required no more skill in making than the fibrous carbon, it is my opinion now, and it was then, that the deposit carbon would be the ideal best carbon for the incandescent conductor of an electric lamp.

X Q. 845. Aside from the difficulty of making, do you now, and have you always considered, that as between two conductors of the same shape and size, one being of carbonized fibrous or textile material and the other being of carbon obtained by electric action pure and simple, that the carbon obtained by electric action would be the superior?

Same objection and notice.

A. I do now consider that the carbon obtained by electric 1275 action is the purer, and therefore, the better carbon intrinsically. I do not remember all my phases of opinion in the past, but I do not remember to have had a different opinion after the discovery by us of the deposit carbons.

X Q. 846. This discovery you claim to have been made, do you not, in March, 1878?

Same objection and notice.

A. About that time.

X Q. 847. Then, is this and has it always been your opinion, that of two conductors of the same shape and size, one of carbonized fibrous material and the other of carbon obtained by electric action, pure and simple, that the latter would be the better, and the former the easier to make?

Same objection and notice.

A. I think that would be true, limiting the one to intrinsic character and the other to the facility of formation and that both would be good conductors. I repeat that I cannot remember all my phases of opinion in the past but I do not recollect having any other opinion.

X Q. 848. Did you in the year 1879, or have you at any time since, considered that it was impractical to make incandescent conductors for electric lamps from carbon obtained from electric action, pure and simple?

Same objection and notice.

A. Not, I think, in the sense that it could not be done. My views of the practicability of manufacturing such conductors have varied from time to time, considering as a practicability the relative cheapness of manufacturing competing incandescent conductors.

Adjourned till Friday, the 29th inst., at 10½ a. m.

1276 FRIDAY, *July* 29, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN proceeded as follows:

X Q. 849. If you desired to make two incandescent conductors of the same size and shape, would it be more difficult to make from a piece of carbon obtained by electric action, pure and simple, such a conductor, than it would be to make it from a block of gas-retort carbon?

Same objection and notice.

A. On the contrary it would be easier to make it from the electric deposit carbon.

X Q. 850. Did Sawyer and Man regard it as impractical to make the incandescent conductors of their lamps from gas-retort carbon?

Same objection and notice.

A. No, I think they could be made from, and we did make them from gas-retort carbon. I am not speaking of the qualities of the conductors when made, but of the making of them.

X Q. 851. If you considered it practical to make conductors from gas-retort carbon, and if, as you say, of two conductors of the same size and shape it would be less difficult to make a conductor from electro-deposit carbon, pure and simple, explain why you considered it impractical to make conductors from carbon obtained by electric action?

Same objection and notice.

A. I have not intended to be so understood, but only to speak of the difficulties of doing it, and the nice work required, and the spoiling of many in manufacture, and as compared with another carbon of most excellent character for the conductor of an electric lamp and which was easily and cheaply made.

1277 X Q. 852. Let me ask you again: Of two conductors of the same size and shape, leaving out of consideration the difficulty or cost of manufacture, am I correct in understanding that you considered a conductor composed of carbon obtained by electric action, pure and simple, as superior to one of carbonized fibrous material?

Same objection and notice.

A. As to the material of which the conductor in each case was made, considering it after carbonization and not before, I mean as carbon, we considered electro-deposit carbon, the purest carbon, and, therefore, the best as carbon. Pure carbon and unadulterated was considered the ideal substance for the conductor of an electric lamp, because carbon, of all substances which are conductors of electricity to any considerable extent, such as to be called conductor, is the only substance that will endure the heat and strain due to the current of electricity used in an incandescent electric lamp. The admixture of any other substance would detract, as I thought then and think now, from this quality of enduring the heat and strain. In this sense we considered the deposit carbon the ideal substance for the conductor of an electric lamp. In obtaining such a pure carbon by electro-deposit it was necessarily made dense and solid throughout the mass of the conductor. Now, in the use of such a conductor, dense and solid throughout its mass, and, perhaps, and probably cystalline in structure, there were difficulties. These difficulties were mainly want of flexibility, as I call it (I don't know as I correctly describe it), and a consequent danger of a liability to breaking, fracture, bursting, flying to pieces of the conductor when heated up. The conductor formed from it alone was a difficult and expensive conductor to make. When fully going and standing in the lamp undisturbed and unjarred in any way, and after the dangers of fracture, bursting and heating up, etc., were passed, it was the best conductor that we knew of, and would stand more heat, and endure longer at an extremely high incandescence, than any
1278 conductor which I knew. Now, in this sense, we considered it the best conductor for an incandescent electric lamp; but electric lamps had to endure jar, shaking, etc., in transportation and use, and the conductors had to be heated up. We found it more advantageous, or thought so, to use a means of gradually heating up with such conductors. The conductor made of carbonized fibrous material retained the structure of the material after it had been carbonized. That structure being open and porous before carbonization, and in its fibres of very small mass and extremely tenuous, considering the fibres separately. In carbonization there was great facility for the escape of impurities and of all substances other than carbon, and for the driving off of such impurities and other substances in carbonization at a high heat, thus producing an extremely pure carbon by reason of the structure of the material from which it is produced. Again, there was great facility of selecting before carbonization, pure and homogeneous material from which there would not need to be driven out so great a number of impuri-

ties as in case such selection could not be made. The material before carbonization was flexible and tough, and therefore capable of being cut to size and shape with facility and without danger of fracture before carbonization. Its mass, by such cutting, was reduced substantially to the mass of the conductor required as a whole, and it therefore furnished facilities for better and more equal carbonization than large masses, and at the same time furnished facilities from its small mass for the escape in the act of carbonization, or the driving out of the substances other than carbon. From its structure it was not very liable to fracture in carbonization, retaining after carbonization the fibrous or textile structure possessed before carbonization, it retained, in large measure, the qualities due to fibrous or textile structure, to wit, flexibility, toughness. It was, therefore, not so liable to fracture by a jar or accident, nor so liable
to breakage, fracture and bursting to pieces in heating up as
1279 the deposit carbon. I have said that it was cheaply
manufactured. Taking, therefore, all the qualities I have enumerated, and the others mentioned in the patent, convenience of making of the required size and form, susceptibility to tempering, both as to hardness and resistance, toughness and durability, it possessed a practical durability, and I considered, although in my experience it would not endure so high incandescence nor so powerful a current of electricity as deposit carbon, under the circumstances I have stated, would endure. I considered that it was the best practical conductor for an incandescent electric lamp that I knew of, taken as a whole.

Answer objected to as irresponsive and argumentative, and as containing many facts concerning which the witness was not interrogated and as stating many conclusions of fact, the facts upon which such conclusions were based not having been asked of the witness and as immaterial.

X Q. 853. Question repeated.

Same objection and notice.

A. Yes, in some respects, but not as a whole as I endeavored to explain in my last answer.

X Q. 854. Leaving out of consideration the cost or ease of manufacture, which did you consider as best on the whole?

Same objection and notice.

A. The conductor made from textile or fibrous material.

X Q. 855. Please tell me which of your two answers is true, and which you desire to be believed by the court, your answer to question 847, or your answer to my last question?

Same objection and notice.

A. Both my answers are true, and I do not wish to be relieved by the court from either.

X Q. 856. Since the hearing of yesterday, have you con-
1280 versed with counsel for complainant in regard to your ex-
amination?

Same objection and notice.

A. I have.

X Q. 857. Did you and he discuss the testimony given by you in the Sawyer & Man, Keith & Maxim interference, or at all consider it; and did you and he at all discuss or consider what your testimony should be if interrogated further as to your preference for carbon of fibrous material or carbon obtained by electric action?

Same objection and notice.

A. We did not at all discuss my testimony given in that interference, nor at all consider it further than this, that I remarked to the counsel that I considered my testimony in that interference entirely consistent with my testimony in this case, in which the counsel agreed with me. We did not at all discuss what my testimony should be in regard to any matter further than this; that the counsel said to me that he thought the word substratum used by me might be liable to misconstruction or convey some false idea, to which I replied that in the connection in which it was used, and with the explanation given, I did not think it could be, to which he said that he would think of it, and we would ask the counsel for defendant to strike out the word substratum, and the words defining its meaning, and it would then leave the sense clear; we read over and examined the matter to make sure to both of us that such would be the fact, and I agreed to ask to have the emendation made. This was the whole substance of our discussion.

X Q. 858. How do you reconcile your answer to cross-question 847 with your answer to cross-question 854?

Same objection and notice.

A. I do not think that an explanation is necessary, or that the answers to these two questions are conflicting; but if explanation
were necessary it will be found in my answer to cross-ques-
1281 tion 852, in which I explained, or endeavored to, the respect
in which I considered the pure deposit carbon conductor superior, but on the whole preferred as a conductor that made from carbonized fibrous or textile material with the reasons for each. I answer, therefore, that if explanation is necessary, I explained by my answer to cross-question 852.

X Q. 859. How does it happen that in answer to a question where you are asked to make no explanation you claim now to have explained what appears to be a discrepancy between your testimony at the last sitting and your answer to a question in effect the same as that asked you at the last sitting?

Same objection and notice.

A. It happens in this wise. You asked me a question, No. 852, which I could not truthfully, fully and completely answer, as it seemed to me, without making the statement I did in respons*ive* to that question, and that statement repeated would be a full and complete explanation, as it happens, of any inconsistency between my two answers, though I deny that there is any actual inconsistency therein; if there is any want of clearness of my intention and meaning in the two answers it will be removed by reading that explanation.

X Q. 860. I repeat now and desire you to answer this question: Do you now, and have you always considered that of two conductors of the same shape and size, one of carbonized fibrous material and the other of carbon obtained by electric action, pure and simple, that the latter would be better, and the former easier to make?

Same objection and notice.

A. Yes, with the explanation I have given in respect to the things in which the latter, the deposit carbon, would be the better, the fibre carbon being the better on the whole, excluding the advantages of cutting, from consideration, and that the former, that is, the fibrous conductor, would be the easier to make.

1282 X Q. 861. Do you consider your answer intelligible?

Same objection and notice.

A. I do.

X Q. 862. Excluding from consideration the cost or difficulty of making, which of the two conductors do you consider the best?

Same objection and notice.

The witness desires to state that his last answer is not what he intended to say in respect to his thoughts or opinions in the past, and has only reference to the present; that he desires to say in this connection that he cannot remember, and will not attempt to state, whether he has "always" thought so, but he does not recollect having any different opinion.

A. I have answered that question over and over again. I repeat it. I prefer, on the whole the conductor made from carbonized fibrous material, and on the whole think it the best. In the respect which I have stated in particular the deposit carbon is, in my opinion, the best.

X Q. 863. Leaving out of consideration the cost or ease of manufacture, please tell me of two carbons of the same size and shape, one made from carbon obtained by electric action, pure and simple, and the other from carbonized fibrous material, which do you consider the best?

Same objection and notice, and further counsel for complainant objects to the question on the ground that the witness has fully and fairly answered the question more than once, and while he does not wish to obstruct the free course of this cross-examination, he most emphatically protests against the obvious effort of counsel to compel the witness to make answers which he has expressed his unwillingness to do, and because this cross-examination appears to be prolonged beyond all reason, merely to waste time and to postpone the judicial determination of the cause.

1283 Witness requests counsel for defendant to permit him to see the answer to the question yesterday No. —. It occurs to witness that he may have answered with reference to "former" when he meant "latter." The question had reference to which I considered the better—the conductor I made from the deposit carbon or the conductor made from fibre carbon in which I used the word "intrinsically" having reference to, as I understood, deposit carbon.

Complainant's counsel explains, on behalf of witness, that the witness off the record courteously requested defendant's counsel, as between gentlemen, to permit him to read the answer referred to, to see if his recollection of it was correct, and defendant's counsel refused to do so.

Defendant's counsel requests the writer to state on the record whether the statement of counsel as to what occurred is correct, and if not, that the writer state in the record what he considers was correct.

The writer says that in the confusion that has recently attended this stage of the examination and *and* the pressure on him to keep up the record, his recollection may be erroneous, but that his understanding was that the request of the witness was declined by counsel.

Witness states, that I have seen the answer and my recollection of it is confirmed.

Defendant's counsel withdraws for the moment the last question and asks the witness the following:

X Q. 864. What do you mean to be understood from your statement on the record, "it occurs to the witness that he may have answered former when he meant latter"?

Same objection and notice as to last but two.

A. I referred to question 847, without knowing its number, 1284 in which the words "latter" and "former" are used; not having it before me, I did not have it distinct and did not know but that I had confounded the one with the other.

Adjourned till Monday, August the 1st, 1887.

MONDAY, *August* 1, 1887.

Met. Present—counsel as before, and the cross-examination of Mr. MAN continued, as follows:

X Q. 865. Do you wish to be understood as having confounded the one with the other?

Same objection and notice.

A. No, I have not.

X Q. 866. Counsel repeats cross-question 863.

Same objection and notice.

A. For practical use as the incandescent conductor of an electric lamp, the one made from carbonized, fibrous or textile material.

X Q. 867. Has this been your opinion since the spring of 1878?

Same objection and notice.

A. I cannot undertake to remember all the phases of opinion I may have had since the spring of 1878, but I — no recollection of having had any other opinion.

X Q. 868. At the time of testifying in the Sawyer and Man, Keith, Maxim interference in 1879, was your recollection of the experiments of Sawyer and Man as clear as it is now?

Same objection and notice on the ground further that the subject-matter in the interference between Sawyer and Man on one side, and Maxim and Keith on the other, was wholly different from the subject-matter in the patent in suit; anything that the witness may have sworn to in that case is utterly immaterial in this.

A. It is fair to assume, I think, that it was.

1285 X Q. 869. Do you remember what the invention of Sawyer and Man was in interference and concerning which you were testifying?

A. Not with particularity, only generally.

X Q. 870. Was it not the application which resulted in letters patent No. 211,262 and 229,335, the application for the former being filed in October, 1878, and of the latter November 29, 1878?

Same objection and notice.

A. I think it had no reference to patent 211,262, dated January 7th, 1879, but had reference to the application filed by Sawyer and Man November 29th, 1878, resulting in letters patent No. 229,335, dated June 29th, 1880, in which the claim in the patent was carbon consolidated and purified by electrically treating it in combination with a carbonaceous substance for the production of electric burners.

X Q. 871. If in 1879 you considered your treated carbon better than untreated carbon, and if you considered a pencil cut from the deposited carbon as a better substance than either for the incandescent parts of electric lights, as testified by you in that interference, how do you reconcile that testimony with your present statement that you have always preferred carbon from fibrous material?

Same objection and notice.

A. Your question states what I have not said, that "I have always preferred carbon from fibrous material." You undertake, without making the distinction as to what I did say, to make me attempt to reconcile something that I have not said with something I have said. I have said that as carbon, pure and simple, the deposit carbon is a purer and better article of carbon than the carbon made from fibrous or textile material, and I have stated the advantages of such a carbon and its disadvantages, and I have further said

that for reasons given by me I preferred and deemed it best
1286 on the whole, the incandescent conductor on an electric lamp made from fibrous or textile material.

X Q. 872. Which do you now consider the better substance for the incandescent parts of electric lights, deposited carbon, pure and simple, or carbonized fibrous material?

Same objection and notice.

A. In the carbons of arc lamps, I now prefer the deposit carbon; for the incandescent portion of an incandescent lamp, I now prefer carbons made from fibrous or textile material. I mean after both are manufactured.

X Q. 873. Do you now, and, so far as your recollection goes, have you always considered that for the incandescent parts of incandescent electric lights you considered carbonized fibrous material as a better substance for such incandescent parts than carbon obtained by electric action, pure and simple?

Same objection and notice.

A. I consider that, for the incandescent parts of incandescent electric lights, carbonized fibrous or textile material is a better substance, all things considered, than carbon obtained by electric action, pure and simple. I do not pretend to remember all my different phases of opinion in regard to such conductors since we first got practically good conductors in the spring of 1878 from carbonized fibrous or textile material, but I have no recollection of having had any other preference in the matter than that I have now.

X Q. 874. What, then, did you mean by your answer 10, in the Keith interference, which I have quoted?

Same objection and notice.

A. Just what I said (to the writer). Copy my words. They are (speaking of the deposit carbon, I say) "the original slip of carbon is deprived of its impurities, which are driven off. The pores are filled with a dense deposit of fine carbon and its outside coated with the same. It appears more uniform, and its outside has a brighter, silvery lustre, instead of being black. It is much stronger,
1287 and less liable to fracture, and almost indestructible by combustion, uniting with very great difficulty, if at all, with any other substance under the influence of heat or electricity, and therefore a much better substance for the electrodes, or incandescent parts of electric lights, and the deposited carbon, when separated from the original pencil, is a better article still for these purposes." I was describing the good qualities of electro-deposited carbon as such, to wit, as carbon, and the question required me to answer in regard to these particulars, and I did so, not, however, confining it to incandescent electric lighting, and I was not comparing a conductor made of such deposit pure and simple for an incandescent lamp with a conductor of carbonized fibrous or textile material, nor with an electrode or electrodes made respectively of the two materials pure and simple.

X Q. 875. This answer says that a treated carbon was "a much better substance for the electrodes, or incandescent parts of an electric light." Were you referring to arc lights or incandescent lights?

Same objection and notice.

A. I cannot remember; but, if I recollect correctly, the interference was declared between Sawyer and Man on the one side, and parties who were claiming to make the electrodes of arc lights in a similar manner on the other side.

X Q. 876. You then go on to say: "And the deposited carbon, when separated from the original pencil, is a better article still for these purposes." By "these purposes," were you referring to the "electrodes, or incandescent parts of electric lights"?

Same objection and notice.

A. I seem to have done so; "electrodes" referring to arc lights, and "incandescent parts" to incandescent lights.

X Q. 877. Did you mean by this answer to say that you 1288 considered a treated carbon as a better substance for the incandescent parts of incandescent electric lights than an untreated carbon, and that the deposited carbon was a better article still for such incandescent parts?

Same objection and notice.

A. I think there is no question that I meant that the incandescing portions of incandescent lights were improved by the treatment. By the latter part of the answer it would seem to me now that I was speaking simply of the quality of the carbon itself, and I was certainly not making any comparison between such conductor of pure deposit carbon only, for an incandescent electric lamp and a conductor made purely from carbonized fibrous or textile material. At that time we were not publishing, so far as I could prevent it, what we had done, and for which we had not applied for patents, and we had not applied for the patent for the incandescent conductor made from fibrous or textile material, and I do not remember to have had in mind, and don't believe that I had in mind, in making that answer, a conductor formed from carbonized fibrous or textile material.

X Q. 888. Now, did you, in fact, at the time this testimony was given, consider that for the incandescent part of incandescent electric lights, the deposited carbon, when separated from the original pencil, was a better article than a treated carbon?

Same objection and notice.

A. I think you take the language too strongly there. I think there should be added to the answer the words "in some respects or for some uses," so that it would read "and the deposited carbon, when separated from the original pencil, is a better article still for these purposes in some respects or for some uses." If you would confine it simply to conductors, and not also to the qualities of deposited carbon, as carbon, which is the sense in which I think it was mainly intended.

Answer objected to as irresponsive.

X Q. 889. Question repeated.

1289 Same objection and notice.

A. In some respects I most certainly did.

X Q. 890. Did you consider it on the whole as a better article?

Same objection and notice.

A. I cannot recollect what I had in mind in making answer to the question, but, according to the best of my judgment, I did not think it a fair in*ter*ference from my answer that I did so in all respects.

X Q. 891. I am not asking you about any answer. I merely wish to know whether you in fact considered at the time of giving the testimony, that for the incandescent parts of incandescent lights, the deposited carbon, pure and simple, was, on the whole, a better article than a treated carbon?

Same objection and notice and not cross-examination; immaterial, incompetent and irrelevant.

A. As to some treated carbons, yes. As to all possible treated carbons I don't think that I so considered or intended to state in my answer.

X Q. 892. Don't you know whether you did or did not consider this a better article than any or all treated carbons?

Same objection and notice and that it is impossible for the witness to state what he had in mind seven or eight years ago when he answered that question, and for the purposes of this case it is not material what he had in his mind or what he thought.

A. I do know that I considered the deposit carbon in and of itself a better article, and I think I knew that I considered then, as I do now, a conductor for the incandescent parts of an electric lamp made from carbonized fibrous or textile material and treated, a better conductor for the incandescent portion of an incandescent lamp that one made purely from deposit carbon, by reason of the greater facilities of making the fibrous conductor and the
1290 properties which it possessed other than mere purity, but I cannot pretend to, nor do not remember, what I had in mind at the time referred to, when I made the answer to the question, as a matter of mere recollection.

X Q. 893. Now aside from the cost or cheapness of manufacture, did you, in fact, consider at this time that for the incandescent part of an electric light a fibrous carbon treated was a better article than the deposited carbon, pure and simple?

Same objection and notice and that the witness has fully answered the question, and he is instructed that he need not answer further unless he chooses.

A. I have already said that I do not recollect to have had the subject in mind at that time or to have considered it at that time.

Counsel for complainant says to the witness, "There, that is an answer to the question," and counsel for defendant insists that what counsel for complainants said to be put down on the record. (Witness says:) "I had said all I was going to."

X Q. 894. By "at this time" in my question I did not refer to the exact date of your testimony, but to the general period of the spring of 1879, I have understood that you have no recollection of your opinions having changed since the conclusion of the Sawyer and Man experiments; with this explanation I repeat my question?

Same objection and notice.

A. You are right in stating that I have no recollection of having changed my opinion that the incandescent conductor of an electric lamp made from carbonized fibrous or textile material was, on the whole, better than one made from deposit carbon, pure and simple, neither have I at present any recollection of having considered the subject-matter, though I may have done so.

1291 X Q. 895. Then it is not true, so far as your recollection goes, that you considered "the deposited carbon, when separated from the original pencil, is a better article for the incandescent parts of incandescent electric lights than a deposited carbon, but what is true is that you considered it better than some deposited carbons, but not as good as others"?

Same objection and notice.

A. I have given no such intimation at all.

Witness here said something about "treated carbons," and counsel for defendant says, "Didn't I say treated carbons? I meant to," when witness insists that the present question and answer shall stand.

X Q. 896. Then it is not true, so far as your recollection goes, that you considered "the deposited carbon when separated from the original pencil as a better article" for "the incandescent parts of an incandescent electric light, than a treated carbon," but what is true is that you considered it better than some treated carbons but not as good as others?

Same objections and notice.

A. I understand the question as referring to my interpretation of my answer in the Keith interference to which you have referred: am I right?

Counsel says, "You are not right."
Then you ask the question without reference to my answer in that case.
Counsel says, "I want to get the fact."

A. I have recollection in regard to it, but it seems improbable to my mind. If I considered it at all that I considered it in any other light than I have heretofore stated it.

X Q. 897. Do you now consider the deposited carbon, pure and simple, as a better article for the incandescent part of an incandescent lamp, than some treated carbons, but not as good as some other treated carbons? I am leaving out of consideration the cost or facility of manufacture.

Same objections and notice.

1292 A. Yes, having reference to the quality of the carbon treated, and character, extent and manner of treatment. Some treated carbons might be good for nothing, by reason of the bad quality of the carbon treated. Some treated carbons might be spoiled for the use intended by either the character or extent of the treatment.

Adjourned subject to notice.

NEW YORK, *Oct. 4th*, 1887—1 p. m.

Met pursuant to arrangement of counsel.

Present: Counsel as before, and the cross-examination of Mr. ALBON MAN was continued as follows:

X Q. 898. Do you recognize the difference between a carbon which is heated by having a carbon deposited upon it for the purpose of making its resistance conform to a given standard, and the case of a carbon upon which a shell of carbon is deposited, the original piece or stick of carbon being a core?

A. I recognize no distinction except in the amount of carbon deposited. The process is the same in both cases, and the effect upon the original stick or piece of carbon the same.

X Q. 899. If a given carbon conductor with a given current have a resistance of, say, a hundred and fifty ohms, caused by the carbon being smaller at one point than its general mass, what amount of treatment would be required to reduce the resistance of the carbon to one hundred and twenty-five ohms, and what effect would such treatment have upon the carbon?

Objected to on the ground that it is immaterial, there being no question in this case as to high or low resistance, or as to treatment of carbon in the manufacture of illuminating conductors.

1293 A. I do not understand what you mean by "treatment." The question does not contain data sufficient to answer specifically. I can answer the question generally. Shall I do so?

X Q. 900. I understand you to have testified that you, in your experiment, used carbons that had not been treated, carbons that had been treated and pencils cut from deposited carbon. By "treated carbons," I refer to such carbons as have deposited upon and in them carbon. Now, where a pencil of carbon had deposited upon it a layer or shell of deposited carbon, how thick was this layer or shell?

Same objection.

A. In our work the shell deposited was sometimes almost inappreciable upon the outside of the carbon. As a whole the main work of deposit being done within the pores of the carbon and at the points of highest resistance in the length of the carbon. In other cases, and in most cases, it was of extreme tenuity, barely visible upon the outside of the carbon; but in cases where we desired to cut it to pieces after treatment, I think the treatment was carried to the extent of depositing from a thirty-second to a sixty-fourth of an inch, or to one one-hundredth of an inch. The thick deposits were only made by us for the purpose of cutting to pieces lengthwise, or removal of the original slip of carbon on which the deposit was made, as I recollect it now.

X Q. 901. Do you remember testifying in an interference between Edward Weston and William E. Sawyer & Albon Man, wherein the invention in issue was "the improvement in the art of manufacturing carbon conductors for incandescent lamps, which consist in building up on a carbon core or base the body of the conductor with carbon obtained and deposited upon the carbon core while surrounded by or saturated with a carbonaceous liquid"?

Same objection.

A. I do.

1294 X Q. 902. I call your attention to the 69th question, and your answer thereto, of your deposition in that interference, as follows:

"R. D. Q. 65. Please state whether all the carbons used by you and your assignees in electric lighting by incandescence so far as you know have been treated according to the process of the invention involved in this interference?

"A. They have (and I think I know in regard to all of them), except so far as mere experiment for testing the quality of carbon went; we tested in lamps experimentally a great many kinds of carbon; but for practical use, made use only of the carbons treated according to this invention."

Is your statement in the testimony I have quoted correct?

Same objection.

A. I think my statement is correct. I think we believed, as I do now, that all the carbons were improved by treatment, and so in our practical work we were in the habit of treating them.

X Q. 903. I call your attention to the following question and answer submitted to and made by you in the Sawyer & Man, Keith & Maxim interference, to which reference has been already made.

"Q. State whether you are one of the parties to the application for a patent by William E. Sawyer & Albon Man for a joint invention of an improvement in carbons for electric lighting, making part of the subject-matter of this interference?

"Same objection.

"A. I am.

"Q. Please to state what that joint invention is?

"A. The production of a dense, homogeneous, pure carbon by electric action and the action of heat, by decomposition and deposit of carbon from hydocarbon gases and fluids. The object being to produce such carbon for subsequent use, principally for electric lighting purposes." 1295

In the deposition from which I have quoted, after describing the apparatus used in depositing the carbon and the manner of depositing the same, you say:

"The result was that the slip or pencil of carbon was heated up to a most intense degree of heat, decomposition of the hydrocarbon gas took place, and pure carbon, very dense, and hard, and homogeneous, was deposited upon the slip or pencil of carbon. After this deposit had gone on until the slip or pencil became of the size we desired we ceased the operation, took out the slip or pencil thus prepared and used it in an electric lamp. * * *

"We cut up the carbons so produced and took out all the original slips, leaving only the prepared carbon precipitated or deposited by the action of heat and electricity."

At the conclusion of your deposition you were asked:

"Q. Since you have commenced to treat carbon as you have described how much of the time have you used it for electrodes, or the incandescent parts of your electric lamps?"

"A. Constantly. Ever since we first began."

It is true that from the beginning of your experiment on treating carbons by deposition, as described in the testimony referred to, up to April 15th, 1879, you constantly used such carbons as the incandescent parts of your electric lamps?

Same objection; and counsel for defendant is requested to state upon the record how the question or answer is material upon any issue in this case, and upon the further ground that the question contains a garbled statement of the testimony quoted from.

Counsel for defendant makes no response to the request.

1296 A. The interference between Keith and Sawyer and Man, as I recollect it, had reference to deposited carbon; my attention in giving my testimony in that case I assume to have been directed to the point at issue and not to matters not at issue, and my answers in that case are to be taken with this in view. I do not recollect of course, at this time the words of my answer; I do recollect that up to the time of this interference we did use treated carbons as the incandescent conductors of an electric lamp, some with the original carbons on which the deposit was made remaining and some of pure-deposit carbon cut from, or separated from the original carbon on which the deposit was made. I also remember that we used carbon for the incandescent portion of the electric lamp on which no deposit was made and to which no treatment was given, and also carbons treated only in the slightest degree, and from that to carbons treated heavily. We were in the habit of generally treating our carbons in some degree. But in this interference the subject-matter, as I recollect, was the deposit carbon, and I do not think my attention was directed to the other things that we had done.

X Q. 904. Mr. Sawyer in that interference, was asked and testified as follows:

"Please to state whether, in the practice of this invention, you build upon the original carbon a consolidated pure carbon which you separate from the original carbons and use as electrodes in electric lighting.

"A. In some cases we do, and in others we allow the original carbon and the shell deposited to remain together.

"Q. Please to state how much of the time you have used this joint invention; since it was first made?

"A. Hardly a week has passed that we have not made a number of these carbons and used them. We never use anything else.

1297 "Q. Have you used, or attempted to use in your electric lamps, carbon pencils of different manufacture, and if yes, please to state what carbons you have used, or attempted to use?

"A. We have not used anything else in our regular lamps but the deposit carbon, but have experimented with several kinds of willow charcoal, with gas-retort carbon and the best French artificial carbons such as Du Bosgas, Grandison and Cane, all infinitely inferior to our invention."

Is it true, as there stated by Mr. Sawyer, that up to April 21st, 1879, the date at which the testimony quoted was given, Sawyer and Man had not used anything else in their regular lamps but the deposit carbon?

Same objection and request repeated. Counsel for defendant is silent.

A. No; and in the alleged testimony you have read Mr. Sawyer does not say so. I understand Mr. Sawyer to say that he used carbons; that is, carbons on which a deposit, more or less, had been made. And he also said that he has used carbons made wholly from the deposit carbon.

X Q. 905. Do you understand from the testimony quoted, him to say that in your regular lamps none but carbon upon which a shell had been deposited and carbon cut from deposited carbon were used by Sawyer and Man?

Same objection and request; no response.

A. Mr. Sawyer, by the testimony quoted, seems to have so stated; nevertheless, I think that his statement should be taken, if at all, as made with reference to the question at issue and that his answer is broader than he intended, and had his attention been called at the time to specific facts and instances, the exceptions would have been made by him in regard to the use of other carbons which actually existed in regular lamps used *used* by us; and I think in answer to the last question quoted that Mr. Sawyer must be 1298 taken as speaking of carbons, not treated, and not of carbons treated, and to have had in mind our general practice of treating our carbons, and the fact of the issue being the ownership of the invention deposit of carbon. I think he did not mean deposit carbon, pure and simple, by reason of his previously quoted answer and because of the fact.

X Q. 906. Now, is it true, that in your regular lamps and for practical use, Sawyer and Man used only carbons made from deposit carbons, pure and simple, or carbons which had been treated by depositing carbon upon them according to the inventions involved in the Sawyer-Man, Keith and Maxim interference, and Weston and Sawyer and Man interference; in the first of said interferences the application of Sawyer and Man, filed November 22, 1878, being involved, and in the latter the Sawyer and Man patent No. 211,262, the application for which was filed, October 15, 1878?

Objection and request repeated; no response.

A. No, it is not true, the difference being in the understanding of the words "regular" and "practical." To the extent that we preferred, and mainly used, treated carbons in our lamps which we exhibited and used for illuminating purposes in our workshops, it is true, because we thought our carbons were improved by treatment according to the process of these patents and applications; but it is not true, if it were intended to say, that we did not use for illuminating purposes in our workshops or exhibit any lamps in which the carbons had not been treated, nor any deposits made in or upon them, because we did use and did exhibit such lamps with untreated carbons; but we did avoid the exhibiting of such lamps when we had those with carbons that had been treated, because we preferred the latter; we thought the treated carbons were better; we were in the habit of running all our lamps for lighting our workshops until they gave out.

X Q. 907. The expressions "regular lamps" and "for 1299 practical use" are not my terms, but were respectively used by Sawyer and yourself in the testimony quoted. According to your present recollection, is it true that, "except so far as mere experiment for testing the quality of carbon went," all the carbon used by you and your assignees (up to Nov. 22, 1882,) an electric lighting by incandescence, so far as you know, have been treated according to the process of the invention involved in this interference—meaning the invention involved in the Weston and Sawyer and Man interference; that "for practical use you made use only of the carbons treated according to that invention"?

Objection and request repeated; no response.

A. In the sense of the matter at issue when that testimony was given, as a general statement and not going into particulars, it would be true, because it was our purpose, finding it advantageous to treat all our carbons, in the sense of the present issue, as to whether we use lamps in which the carbons were not treated, which were practical lamps, if there be such an issue in this case, it would not be true, because we did in running our lamps with carbons before treatment find some that were good. Nevertheless, it was our purpose when putting up the same kind of carbons in our lamps which we designed for practical use, to have them treated before being put into the lamps.

Defendant's counsel requests examiner to note that complainant's counsel here says to witness, "Would you like to refer to any of those lamp globes"?

A. I have recently refreshed my recollection by reference to old lamps and parts or lamps with tickets upon them, stating whether the carbons were treated or not treated, used by Sawyer and Man in the fall of 1878, and the winter following, 1879.

X Q. 908. I am anxious simply to ascertain what the fact 1300 was. Does your answer to R. D. Q. 65 in the Weston-Sawyer and Man interference state what is true?

Objection and request continued; no response.

A. In the sense of that interference I think it is true; so far as the question at issue in that case is concerned, it is true.

X Q. 909. The answers, as I understand you, contain a truthful statement of what the fact really was?

Objection and request continued; no response.

A. It is, but it does not state all the fact, that some of the lamps with carbons not treated were good lamps.

X Q. 910. The fact I am interested in ascertaining is, whether it is true that for practical use you made use only of the carbons treated according to the invention in that interference involved?

Objection and request continued; no response.

A. If you mean by that, that we did not make any lamps which we practically used in which the carbons were not treated, it is not true, because we did light up our shops in whole or part with lamps in which the carbons were not treated, and they were good lamps, but in the sense that the best lamps that we made, and which were our pattern lamps, and to which we desire to conform the lamps which we should make, these being called our practical lamps and in which the carbons were treated, it is true. In other words, we did not mean to stop with the invention at issue in this case, but intended, and almost always did add to our lamps the invention of treatment.

X Q. 911. At the time of the conclusion of the Sawyer and Man experiments in March, 1879, had Sawyer and Man decided upon a lamp, which could be correctly described as their "regular" lamp, and which they designed for practical use?

A. I think they had upon several.

X Q. 912. Do you mean to be understood that they had 1301 not decided upon any one lamp, but that they had several lamps which they considered equally good?

A. They had several lamps which they considered good and practical.

X Q. 913. What I wish to know is whether they had decided upon any one lamp as being the best and the one they intended to introduce for practical use?

A. They had decided upon several different lamps which they thought were best for use in different places and under different circumstances.

X Q. 914. And had not, as I understand you, determined finally upon any one type or character of lamp?

A. They had, in a certain sense, determined upon one type or character of lamp, that is, the incandescent lamp, for most uses and most purposes; but of this incandescent lamp they had decided that one kind was best for use in one place and for one purpose, and other kinds for use in other places and for other purposes.

It is proper to add that in addition to this Mr. Sawyer had of himself made up his mind in regard to some arc lamps in which he alone took part, and in a semi-incandescent lamp, which he called a feeder lamp, in which I think we both took part, but in regard to which I do not think I had come to a favorable conclusion.

X Q. 915. You have said that when you left Centre street you had a practical and successful lamp. Had you then decided upon any one type of lamp as your standard lamp, or did you have several standard lamps of different types and constructions?

A. We had several lamps of different types or constructions, all of which we thought were practical lamps. One we considered then the best kind of lamp which we had made, so far as we knew.

X Q. 916. Was there any one type of lamp which you 1302 considered best, and which you designed to introduce commercially?

A. Yes, and we also intended to introduce commercially all the types which we considered good.

X Q. 917. You had not then, as I understand, determined upon any one type of lamp, but you had several lamps of different types, all of which you intended to introduce?

A. We had decided upon a type of lamp which we thought would be most useful for most purposes, and which we considered the best that we had so far made, and we had decided upon other types of lamps, all incandescent, which we intended to introduce for some purposes and some uses.

X Q. 918. Up to 1882, were any of your lamps used for "practical use"?

A. Yes, a great many of them.

X Q. 919. Did these lamps all have carbons made from deposit carbon, pure and simple, or carbons which had had carbon deposited upon them according to the invention of the patent of Sawyer and Man involved in the Sawyer and Man-Weston interference?

A. No; not all of them, but most of them.

X Q. 920. Then, the broad statement you made in the Sawyer-Man-Weston interference that for practical use the only carbons used were those of the kind mentioned in my question, was not true, was it?

A. Yes; in the sense of that interference it was true. In practice our carbons were treated; but some of the lamps we used for the illumination of our shop were not treated. We did not intend to put out for use by others any lamps in which the carbons were not either deposit carbons or carbons treated by deposition according to our invention, but we used for our own illumination and sometimes exhibited lamps in which the carbons were not treated; in other
words we intended to add to our other inventions in regard
1303 to carbon for electric lamps the invention in regard to treating the carbons before putting them out for use, and I do not remember that any lamps were put out in which the carbons were not treated, or of deposit carbon, pure and simple.

Adjourned till Wednesday, the 5th inst., at 1 p. m.

New York, *Oct. 5th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. Albon Man was continued as follows:

X Q. 921. Where we have been speaking of treated carbons or carbons made of deposit carbon, pure and simple, or carbons with carbon deposited on or in them, do you understand we have been referring to the carbons and the carbons with carbon deposited on or in them referred to and described in the Sawyer-Man patent No. 211,262, the application for which we filed October 15, 1878, and which was involved in an interference with Edward Weston and referred to and described in the Sawyer-Man application, filed November 22, 1878, and involved in an interference with Keith & Maxim?

Last objection and request continued. No response.

A. I assume that your reference- to patents and applications are correct. If so, yes; I mean carbons produced or improved according to our patents for those purposes.

X Q. 922. Did you consider carbons made from willow charcoal, gas-retort carbon, and the best French artificial carbons inferior as incandescent conductors to the deposit carbon or carbons that had carbon deposited on or in them?

Objection and request continued. No response.

A. As to the French carbons and gas-retort carbons, yes;
1304 as to the carbons made from willow, I do not think so; certainly not after treatment. I am not certain, however, in regard to my recollection of my thought at the time of giving tes-

timony in those cases, and I may have thought, while testifying, that the deposit carbon, pure and simple, was better for an incandescent conductor than the willow carbon alone and before treatment.

X Q. 923. Do you know what Mr. Sawyer's opinion was?

Objection and request continued. No response.

A. I do not recollect, if I knew at the time.

Adjourned till Friday, the 7th inst., at 1 p. m.

NEW YORK, *Oct. 7th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 924. In the testimony from the Sawyer-Man-Keith-Weston interference, Mr. Sawyer testified that Sawyer and Man had experimented with several kinds of willow charcoal, with gas-retort carbon and the best French artificial carbons, but that all were "infinitely inferior to our invention," referring to carbons made from deposit carbons or carbons which had had carbon deposited upon or in them according to the process of your patents. Do you know, of your own knowledge, whether such was Mr. Sawyer's opinion?

Question objected to on the ground of incompetency, immateriality, and irrelevancy, and as not cross-examination, there being no question in this case respecting the comparative merits of different kinds of carbon.

1305 Counsel for the plaintiff, or complainant, requests defendant's counsel to state upon the record how the question is material upon any issue in the case

No response from defendant's counsel.

A. I understood Mr. Sawyer, by the word carbon in the testimony spoken of by you, to mean the illuminating conductor of an incandescent electric light. I think I know of my own knowledge that he considered such conductors made from the carbon he mentioned without treatment to be inferior to such conductors made of the same material and treated after the manner of our patents. I think, also, I know that as the matter of carbon, referring to its quality for the purposes of an incandescent electric lamp, he considered the quality of the deposit carbon, pure and simple, superior to that of any other carbon, but that at the same time, by reason of the difficulty and expense of making certain kinds of conductor from that carbon, and its liability to fracture, he did not consider the conductor made wholly of that kind of carbon the best conductor.

X Q. 925. At the conclusion of the Sawyer-Man's experiment, did you and Mr. Sawyer agree as to what was the lamp and type of lamp you intended to introduce?

Same objection.

A. Yes, we agreed as to all the lamps and types of lamps which we intended to introduce except one, which was what he termed the feeder lamp, which was semi-incandescent and semi-arc lamp; but it is proper to say that in regard to these different types and kinds of lamps, other than a feeder lamp, my views and those of Mr. Sawyer at that time, were not entirely in accordance as to the comparative value of the different lamps which we considered good and intended to introduce.

X Q. 926. Among the patents applied for by Sawyer and Man prior to their separation, I find but two lamps shown and
1306 described, and these are the lamps described and shown in
patents No. 205,144 and 210,809; now did you regard the lamps shown and described in these patents as practical incandescent lamps for commercial purposes?

Objected to as incompetent, irrelevant and immaterial

A. Yes, we did consider them practical for commercial purposes and they were so at the time.

X Q. 927. Did you ever construct any lamps substantially like the lamps shown in these patents?

Same objection.

A. Yes, a great many.

X Q. 928. Do either of these patents represent in substance the type of lamp you had decided upon producing for commercial purposes?

Objected to as immaterial.

A. Yes, they both represent, in whole or in part, types of lamps which we intended to introduce.

X Q. 929. At the time you applied for these patents did you consider the lamps shown in them as the best lamps for commercial purposes that you had made?

Objected to as immaterial.

A. I cannot recollect as to the first one; as to both, we considered them good lamps. As to the second one, I think that at the time of the application for the patent for it, we had made a lamp which in some of its features we considered better than either of these.

X Q. 930. Did you ever apply for a patent for this lamp that you considered better, or show or describe it in any application?

A. Yes, before the application for the patent No. 210,809, which was filed November 5th, 1878, we had presented to Mr. Broadnax (counsel for the Electro Dynamic Light Company) the features or particulars of a lamp differing from this in some respects, and which we considered better than the one for which we were then ap-
1307 plying for patent, or the one which we had previously pat-
ented, and asked him to apply for patents for the same. Mr. Broadnax had the subject before him for this purpose up to the time of the separation of Sawyer and Man in March, 1879, and from that

time forward until an application was at last made for these features, or some of them, in the early part of January, 1880.

After the word "yes" the answer is objected to by defendant's counsel.

X Q. 931. Now taking these two patents, 205,144 and 210,809, and the application for the patent in suit as originally filed, did you consider that lamps constructed substantially according to the lamps shown and described in these patents and that application as the best lamps you had made and best adapted for commercial purposes?

Same objection.

A. No; the drawings and description in all these applications do not show the best lamps we made accurately; they only illustrate the invention sufficiently to obtain the patents for which we were applying.

X Q. 932. Did you intend, and do you think that the two patents as granted and the application for the patent in suit as originally filed, described the lamps sufficiently accurately to enable a person skilled in the art of incandescent lighting as it then existed, or in the art to which it was most nearly allied, to make and construct such lamps?

Same objection again as immaterial.

A. Yes, we so intended, and I think the illustrations and description sufficient for that purpose.

X Q. 933. I notice letters patent 210,809 refer to letters patent 205,144, and state that in letter-patent 205,144 you "have shown and described an electric lamp differing not essentially in so far as its main features are concerned from that of our present invention," and the object of the invention of patent 210,809 is stated to be "to produce a lamp more tasteful in appearance and better 1308 adapted to afford a successful electric light;" in the application for the patent in suit, as originally filed, the invention is stated as constituting an "improvement upon the apparatus shown in letters patent 205,144;" now if a person skilled in the art should take these two patents and this application, as originally filed, and construct a lamp according to the drawings and specifications of the two patents and the application for the patent in suit, as originally filed, would that lamp represent the type of lamp you considered as the best lamp you had made?

Objected to as immaterial and speculative.

A. It would doubtless be of the general type of our best lamps, but would not be the same as our best lamps in all probability unless made by ourselves or our assistants.

X Q. 934. Did you consider that the size or resistance of the incandescent conductor as being of importance to the construction of the lamp, the arrangement of the lamps, or the kind of generators to be employed?

Same objection.

A. Yes.

X Q. 935. In lamps constructed according to patent 205,144, what was the resistance of the incandescent conductor?

A. The lowest resistance that I remember in any such conductor was a fraction of an ohm, it seems to me now about one-half an ohm; I cannot recollect the highest resistance; the nearest approximation I can now give was thirty or forty ohms; if they have been higher and could practically have been higher, a conductor for such a lamp could have any resistance between the resistances I have named, or up to a much higher resistance, and still be operative, if proportioned to the current used.

X Q. 936. You don't answer my question, as it seems to me; what I wish to know is what the resistance of an incandescent conductor would be in a lamp constructed according to patent 205,144.

Objected to as immaterial.

1309 A. It might be any resistance, if proportioned to the current used.

X Q. 937. What would be the length and diameter of the incandescent conductor of the lamp constructed according to this patent?

A. It might be of any length up to one inch and a half or two inches or longer; its diameter would have to be proportioned to the length in such manner as to give the resistance required for the current used.

X Q. 938. If you considered the resistance of the conductor, or its length or size as important, why did you make no mention of these things in the patent?

Same objection and request.

A. Because the resistance, length and size are of relative importance only within practical limits, and could be safely left to the electrical expert who should build lamps to estimate and proportion to the currents available to them for use; in this answer I am not to be understood as stating anything in regard to the advantages or disadvantages of using currents of higher or lower electro-motive force, but only as speaking of an operative lamp.

X Q. 939. Did you designedly omit in this patent any statement of what the resistance of the incandescent conductor was to be?

Same objection and request.

A. I do not think we had any such design; I suppose we did not think it was necessary.

X Q. 940. Now, turning to patent 210,809, what would the resistance of the incandescent conductor of a lamp constructed according to this patent be?

Same objection and request.

A. I answer the same as in regard to the previous lamp.

X Q. 941. Now, take the application for the patent in suit as

originally filed, what would the resistance of the incandes-
1310 cent conductor of a lamp constructed in accordance with the description therein contained be?

Same objection and request.

A. It might be anything from the fraction of one ohm up to one hundred and fifty ohms or more, if proportioned to the current available, and be an operative lamp.

X Q. 942. These two patents, and this application, as originally filed, being entirely silent as to what the resistance of the incandescent conductor should be, a person constructing a lamp under these patents and this application would be called upon to exercise his own judgment as to what the resistance, length and diameter of the conductor should be?

Same objection and request.

A. He would be at liberty to do so, I suppose, in accordance with the currents available to him; he must exercise the knowledge and intelligence of an expert having certain currents available to proportion his resistance to his currents, and also to proportion his conductors or leads to the incandescent portion of his lamp, so that the resistence of the conductors and leads would be so much less than that of his lamp that the work would be done where he wanted it, to wit: in the incandescent conductor of the lamp.

X Q. 943. At the time the application for the patent in suit was filed had Sawyer and Man determined upon what the resistance of the incandescent conductor of the lamps shown in the patents and in the application for the patent in suit should be?

Same objection and request.

A. They had not determined upon any fixed or given resistence for their lamps, to the best of my recollection. They had ascertained the advantages and disadvantages of higher and lower resistance in their lamps for the currents which they used.

1311 X Q. 944. Had they determined, at the time of filing the application for the patent in suit, how their lamps were to be arranged, whether in series or multiple arc?

Same objection and request.

A. They had determined that for some purposes and in some places lamps would be used singly and alone; and that in some places and for some purposes they would be arranged in series; in some, in multiple arc; and in some in multiple-arc series.

X Q. 945. Had they decided upon any one form of arrangement of lamp as being the best for general commercial purposes?

Same objection and request.

A. I do not remember that we had settled upon any one system to the exclusion of any or all others.

Adjourned till Saturday, the 8th inst., at 1 p. m.

New York, *October 8th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before and cross-examination of Mr. Man continued as follows:

X Q. 946. Was it the intention of Sawyer and Man to use the same lamp if arranged in series or in multiple arc?

Same objections and request.

A. That would depend on circumstances and the current available. The same types of lamps.

X Q. 947. You have repeatedly spoken of "currents available," was it your intention to make the lamps conform to such generators as might be possessed, and not to make the generators conform to the character of the lamp?

Same objection and request.

1312 A. It was our intention to make lamps suitable for different currents, and also to make or procure generators or sources of electricity, such as dynamos and batteries, to run a fixed number in each case of particular lamps, the lamps being in each such case of the same kind.

X Q. 948. In your answer to question 944 you say "Sawyer and Man had not determined upon any fixed or given resistance for their lamps," had they determined approximately what the resistance of the incandescent conductor should be?

Same objection and request.

A. They had determined what the resistance of lamps should be for different currents and different arrangements of lamps, as these resistances varied in most cases of actual use; they had not determined or fixed upon one certain resistance for all incandescent electric lamps, either approximately or positively.

X Q. 949. According to the art as it exists, do you know whether it is true that where the lamps are arranged in multiple arc the lamps are of higher resistance, one hundred ohms or more, and where they are arranged in series, they are of low resistance, less than ten ohms?

Same objection and request.

A. No; such is not the fact, without reference to other things which you do not state; a few lamps of low resistance, ten ohms or less, are frequently run in multiple arc; if very many lamps are to be used, or if the lamps are quite distant from the source of the electricity, to be run in multiple arc would require enormous quantity of current and expensive leads or conductors, where the lamps are distant from the source of electricity; for this reason and for others, lamps run in multiple arc are of high resistance. This matter is largely a question of distribution of currents and expense and of nothing inherent in the lamp. It is one of those questions of the currents available. Again, lamps run in series, 1313 each one in itself a resistance, add resistance to resistance for every lamp added to the series. It is evident that if higher-resistance lamps were used, in such cases the total resistance of a large number of lamps would become enormous, requiring currents of correspondingly high electro-motive force, soon reaching the limit of generators of electricity or passing beyond control and becoming dangerous. It is evident, therefore, that lamps in series should be of low resistance. This then is a question of currents available, but there is no such general practice as precludes the running lamps of low resistance in multiple arc or the running of lamps of high resistance in series, within the limits of practicability.

X Q. 950. Do you know how, in isolated and central station plant at the present time, the lamps are arranged?

Same objection and request.

A. I understand that they are usually arranged in series or multiple arc. I am not familiar with the details of recent work.

X Q. 951. Are you familiar with the incandescent lamps that had been patented prior to the labors of Sawyer and Man?

Same objection and request.

A. I have not them in mind at present.

X Q. 952. Would a lamp constructed under patent 210,809 be of higher resistance than one constructed under patent 205,144?

Same objection and request.

A. Not necessarily; it might be and it might not.

X Q. 953. I understand from your testimony it would depend upon the wish of the person constructing the lamp and upon anything contained in the patents?

Same objections and request.

A. I think largely so; a person could make a lamp of higher or lower resistance of either kind.

1314 X Q. 954. Now take the application for the patent in suit, as it was originally filed. I understand from your testimony that a person constructing a lamp following it and the patents to which it refers, is left in ignorance as to what the resistance of the lamp should be?

Same objection and request.

A. That depends upon whether he is an ignorant person, or an expert; he is left at liberty to adopt such resistance as he wants.

X Q. 955. Is it now your opinion that at the time letters patent 205,144 were granted, a person skilled in the art could construct a lamp according to that patent and make his lamp either a fraction of an ohm, or forty or fifty ohms resistance?

Same objection and request.

A. Yes.

X Q. 956. What change, if any, would have to be made in the lamp to make it in the one case the fraction of an ohm, and in the other, forty or fifty ohms resistance?

Same objection and request.

A. Simply to make the incandescent conductor of the resistance be required, and adapt the other portions of the lamp to this conductor.

X Q. 957. How could he make the resistance of the conductor in one case the fraction of an ohm, and in the other forty or fifty ohms?

Same objection and request.

A. By making the conductor of the resistance short and large and of carbon of high conductivity; in the case of high resistance, by making the carbons long and small and of carbon of high resistance.

X Q. 958. And this, you think, would be known to a person then skilled in the art?

Same objection and request.

A. Yes.

1315 X Q. 959. Well, what carbons were then known to be of high resistance and what of low?

Same objection and request.

A. The different qualities of French carbons, so called, were known to electricians to be of less resistance than the ordinary gas-retort carbons. They were also known to be of less resistance than charcoal and vegetable carbon. I think the resistances of different carbons were tested by electricians before that time.

X Q. 960. Was it then your opinion, that electricians knew that the resistance of the conductor would depend upon its length and cross-section and the kind of carbon of which it was to be made?

Same objection and request.

A. Yes, it was well known to electricians that increasing the length of a conductor increased its resistance and that increasing the size or section of a conductor diminished its resistance, and it was known that different carbons had different resistance of same size, section and length, and electricians knew how to test the resistance of carbon and other substances.

X Q. 961. Now I understand you to have made lamps shown in patent 205,144, where the resistance of the carbon of such a lamp was the fraction of an ohm. What was the length and cross-section of the incandescent conductor in drawing marked E′?

Same objection and request.

A. I do not know whether I can recollect with accuracy the size of those carbons; I can get an approximation. They were less than half an inch in length and more than a twentieth of an inch in cross-section; I should say between a twelfth and twentieth; I recollect one of a tenth of an inch cross-section.

X Q. 962. Are you answering my question with reference to an incandescent conductor having the resistance of a fraction of an ohm?

1316 Same objection and request.

A. Yes.

X Q. 963. What was the character of the carbon?

Same objection and request.

A. We used several kinds of carbon in those low resistances, some of them French carbons treated and untreated, some of them of deposit carbons pure and simple. I think some of gas-retort carbons and some of vegetable-fibre carbons, treated and untreated; with all these carbons it is my recollection we made lamps of less than one ohm resistance.

X Q. 964. Now, if a person wanted to make a lamp under this patent with an incandescent conductor of fifty ohms resistance, what would he have to make the length or cross-section of this carbon?

Same objection and request.

A. I cannot tell without knowing the carbon that he was using and its resistance, and then only by experiment.

X Q. 965. Cannot you tell me approximately; I understand you have made such lamps with such carbons?

Same objection and request.

A. Yes, we made lamps of forty or fifty ohms resistance. I cannot recollect the size and length of the carbon with accuracy.

X Q. 966. I don't ask you to tell me with accuracy, but approximately?

Same objection and request.

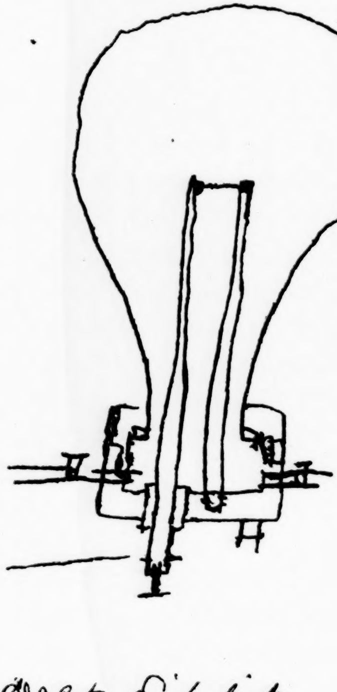
A. From general recollection only, which may be quite inaccurate, my impression is, two inches or more in length and less than a thirty-second of an inch in diameter.

X Q. 967. What was the total length of the conductor between D and *a*?

Same objection and request.

A. I mean by the length I have given, the length of the incandescent portion of the conductor; we did not make all our
1317 lamps under that patent with the clamp G, but omitted it in
many of the lamps as shown in Fig. 9 of that patent; the length was anything above the clamp G; a small fraction of an inch would be sufficient, but we used carbons of more than three inces total length including the incandescent portion and the portion above the clamp G, this total distance from D to *a*.

No. 286.
E. E. Light Co.
v.
McK. Light Co. } p 1318



Defts Exhibit
Man Sketch No 1
October 11 1887

X Q. 968. Now, this patent describes very minutely the lamp and its construction, and contains a drawing in illustration of the lamp. Do you think that following the patent a person could use an incandescent conductor two inches in length and a thirtieth of an inch cross-section in this lamp?

Same objection and request.

A. Yes, I think so, and my recollection is that we did so.

X Q. 969. In your patent 210,152, applied for October 19th, 1878, you state "we have found that the internal resistance of a lamp such as that of letters patent 205,144 is not far from six-tenths of an ohm." Was that statement true?

Same objection and request.

A. Yes, if it was made of that resistance. I do not think that we ever intended to say that it could not be made of higher resistance.

X Q. 970. Now you are one of the applicants for this patent, cannot you give me what the resistance of a lamp such as is here shown was?

Same objection and request.

A. I could only tell you by measuring it; if you desire to have me state what the ordinary resistances of lamps made by us was, I can tell you or approximate it.

X Q. 971. You cannot then say whether a lamp constructed in strict accordance with this patent would be a high or low resistance lamp?

Same objection and request.

(Here follows diagram marked p. 1318.)

1319 A. I can only say that they might be made of a resistance less than one ohm or of a resistance of forty ohms.

X Q. 972. Equally well?

Same objection and request.

A. There would be more difficulty in making the higher-resistance lamp.

X Q. 973. In making the higher-resistance lamp, would any alteration have to be made other than in the length, cross-section or material of the carbon?

Same objection and request.

A. No, only in proportioning the other parts of the lamp to the carbon used.

X Q. 974. Would the high-resistance lamp be as durable as the low-resistance lamp?

Same objections and request.

A. Probably not.

X Q. 975. All that you have said concerning the lamp of patent 205,144 is equally true, as I understand you, of the lamp constructed under patent 210,809?

Same objection and request.

A. Yes, I think so.

X Q. 976. A lamp under this patent could be made, and, as I understand you, was made of either less than an ohm or more than forty ohms resistance?

Same objection and request.

A. Yes, up to forty ohms.

X Q. 977. Now, did you ever make a completed lamp, such as shown in patent 205,144?

Same objection and request.

A. Yes, substantially.

X Q. 978. How many completed lamps?

Same objection and request.

A. I do not know.

X Q. 979. Before you left Centre street, how many?

Same objection and request.

1320 A. Several; I don't know how many.

X Q. 980. What is your best recollection?

Same objection and request.

A. My recollection is that we made a considerable number of lamps like that complete and entire; that we used the same parts of the lamp put in different conductors into the same globe, modifying the internal works of the lamp and using different conductors in the same lamp or globe a great many times. I cannot say how many.

X Q. 981. What is your best recollection as to the number of lamps substantially like that shown in patent No. 205,144, you made in Centre St.?

Same objections and request.

A. I have no recollection of it, other than I have stated.

X Q. 982. Can you not give me any idea whatever whether it was as many as a hundred, or as few as two or three?

Same objection and request.

A. It was not so few as two or three; I do not think it was a hundred.

X Q. 983. Do you think it was fifty?

Same objection and request.

A. I don't know.

X Q. 984. Do you think it was twenty-five?

Same objection and request.

A. I think it was more than twenty-five.
X Q. 985. As many as thirty, do you think?

Same objection and request.

A. Yes, I think it was more than fifty, but I don't know; I mean by this, not separate entire lamps, because the parts were used over and over again.
X Q. 986. What I want to get at is, your best recollection as to the number of separate and entire lamps, as shown in patent 205,144, were made by, or for, you and Mr. Sawyer while you were at 43 Centre St.?

1321 Same objection and request.

A. That I cannot give you.
X Q. 987. Can you not give me any approximate idea?

Same objection and request.

A. I can guess at it and that is all I can do.
X Q. 988. Can you not state between certain limits?

Same objection and request.

A. Yes, I can state to the best of my judgment within certain limits, and that is at present, and I might think differently upon calling to mind other circumstances, from fifteen to twenty-five separate and entire lamps of the kind shown in this patent, or similar to it, while we were at 43 Centre St., and perhaps a hundred separate and distinct lamps, counting those in which the parts were used over.
X Q. 989. Now, what is your best recollection as to the number of separate and entire lamps of the kind shown in letters patent 210,809 made by you while at 43 Centre St.?

Same objection and request.

A. I don't remember.
X Q. 990. Tell me your best recollection.

Same objection and request.

A. We made some, I don't remember how many, perhaps as many as of the other, but I could not say, nor could I say that they were exactly like those shown in that patent; they were similar.

Adjourned till Monday, the 10th inst., at 1 p. m.

1322 Monday, *October 10th*, 1887.

Met pursuant to adjournment.
Present: Counsel as before, and the cross-examination of Mr. Man was continued as follows:

X Q. 991. Do you mean to be understood, that according to your best recollection at the present time, you made about fifteen to twenty-five separate and entire lamps of the kind shown in letters patent 210,809, while at 43 Centre street?

Objected to as irrelevant and immaterial and counsel is requested to state upon the record how this line of examination is either competent or material for cross-examination. No response.

A. While at 43 Centre street, yes; but I mean to be understood at the same time, that I do not know the number, and that is a mere impression left on my mind. It is between eight and nine years since we made them.

X Q. 992. Now, of the kind of lamps shown in patent 205,144, were the conductors of about the same resistance in these complete and entire lamps?

Same objections and request; no response.

A. No; I should think not.

X Q. 993. Were they of the same general length and diameter?

Same objection and request; no response.

A. No; I should think not.

X Q. 994. Do you remember between what limits the resistance varied, and the length and diameter of the conductor varied?

Same objection and request; no response.

A. No; I do not, to state it with accuracy.

X Q. 995. Do you remember approximately?

Same objection and request; no response.

1323 A. Yes, I think so; that is to say, I have an impression in regard to it in my mind.

X Q. 996. If you have, state it.

Same objection and request; no response.

A. The resistance from the fraction of one ohm up to forty ohms, or possibly fifty or more; the size from less than ha*ve* an inch in length to two or three inches in length; the diameter from a tenth of an inch or more to a thirty-second of an inch or less.

X Q. 997. As I understand you, you had not determined upon any standard size or resistance for the conductors of these lamps.

Same objection and request; no response.

A. I have testified fully in regard to that matter. Your generalization is too large. We had not determined to make any one of the lamps to the seclusion of another.

X Q. 998. Well, you did think that the lamp of this patent would be a practical lamp for commercial purposes, with either a comparatively short, thick, low-resistance conductor, or a long, thin, high-resistance conductor?

Same objection and request; no response.

A. Yes; and we had most urgent requests, or demands, to sell lamps of both kinds.

X Q. 999. What we have been saying of the lamp under 205,144 is equally true of the lamps under 210,809?

Same objection and request; no response.

A. Yes.

X Q. 1000. Now, while you were at 43 Centre street, did you make any lamps in which the conductor was of paper, or carbonized fibrous or textile material?

A. Yes.

X Q. 1001. About how many complete and entire lamps were made having such conductors, at 43 Centre street?

A. That I can't say.

1324 X Q. 1002. According to your best recollection, about how many?

A. I have no distinct recollection in regard to the number. I have no record of them, and as we continually used over the parts of lamps with different carbons substituted in the same lamp, I do not think I could even approximate the number.

X Q. 1003. Can you give me no idea?

A. No, I can't, for the reason that we so often changed our lamps, and changed the internal works and carbons, using the same globes or glass envelope, that I cannot distinguish one from another.

X Q. 1004. Can you not give me some idea, whether as many as a hundred or as few as two?

A. We made more than two separate, distinct and complete lamps, and less than one hundred, in which this kind of carbon was employed.

X Q. 1005. Were as many as ten separate and distinct lamps in which this kind of carbon was employed made at 43 Centre street?

A. I cannot tell.

X Q. 1006. As many as twenty?

A. Same answer.

X Q. 1007. As many as fifty?

A. Same answer.

X Q. 1008. As many as seventy-five?

A. I should think not.

X Q. 1009. As many as sixty?

A. I should think not.

X Q. 1010. As many as fifty?

A. I think not, but I can't tell.

X Q. 1011. As many as forty?

A. Same answer.

X Q. 1012. As many as twenty?

A. I will tell you simply what I think, and my impression
1325 is based upon a review in my own mind of the work we did
at Centre street. I think we set up one or two complete sets of lamps, in which the vegetable-fibre carbon was employed, and in which the parts of the lamps had not been used with any other carbons. The sets were composed of from eight to twelve lamps. Now I may be mistaken in regard to all the parts of these lamps not having been used with other carbons, and it may be that we set up more entirely distinct lamps with these carbons, or less. I think we set up and ran of all kinds of lamps with these carbons, in

the neighborhood of fifty to a hundred lamps. It may have been more and it may have been less, while we were at 43 Centre street.

X Q. 1013. Are you confident that as many as ten lamps were run to incandescence in Centre street, which lamps had conductors of fibrous or textile material?

A. Yes, very many more than that; from fifty to a hundred.

X Q. 1014. Do you remember the first completed lamp made by you in Centre street which had a conductor of this kind?

A. No, I do not, as a separate and distinct lamp. I remember the form of the globe in which we first used conductors of that kind.

X Q. 1015. Do you remember — the first attempt to run to incandescence a conductor of carbonized, fibrous or textile material was *whether* in what might be called a lamp or in rude experimental apparatus?

A. I do remember it.

X Q. 1016. Now please to state what the first experiment was which you and Mr. Sawyer conducted at 43 Centre street on running to incandescence a conductor of carbonized, fibrous or textile material?

A. It was an attempt to pass the current through a piece of paper on Mr. Sawyer's desk.

X Q. 1017. What kind of paper?

1326 A. My impression is that it was a piece of blotting paper.

X Q. 1018. Had it been carbonized?

A. No.

X Q. 1019. What was its size and shape?

A. I should think about an eighth of an inch wide, more or less, and a couple of inches long, a long, narrow slip cut from a sheet of ordinary blotting paper.

X Q. 1020. How did you connect your conductors with this blotting paper?

A. It lay upon the table and we put the terminals down upon the paper as it lay there.

X Q. 1021. Well, what happened?

A. Nothing, no current passed.

X Q. 1022. Was the paper injured?

A. No, sir.

X Q. 1023. What was your object in trying this experiment?

A. I forgot what we had in view at the moment.

X Q. 1024. What information did you derive from it after it had been tried?

A. That the paper formed a good electrical resistance or insulator.

X Q. 1025. Didn't you know that before?

A. No, we did not know how good that particular kind of paper would be as an insulator.

X Q. 1026. Did you know what the electro-motive force of your generator was at the time?

A. I don't think we did.

X Q. 1027. Did you know about what it was?

A. No, I don't think we did; only that it was a considerable number — volts.

X Q. 1028. About how many?

A. I don't recollect that we thought of it at the time.

X Q. 1029. Which of the dynamos that you had in Centre street were you using at this time?

1327 A. I think the one in the basement, an arc lighting dynamo.

X Q. 1030. Do you remember what the next thing that was done by you and Mr. Sawyer at 43 Centre street was, in relation to the use of fibrous or textile material as an incandescent conductor?

A. Yes.

X Q. 1031. Please state.

A. We next drew a fine line with a piece of graphite on this same slip of paper or a similar one, put a little pile of graphite at each end of the line, pressed it down and placed the electrical terminals on the piles and endeavored to pass the current through it. Not succeeding, we increased the size of the line and approached the pile of graphite to each other at the extremities until the current finally passed along the line. We had made by repeated markings and indentation on the line which we filled up with graphite, increasing the size of the lines, and pressed it down. The current passed by a series of sparks along the line of graphite and the paper was burned along the line, and charred through to the under side of it.

X Q. 1032. With reference to the time of the first experiment, when was this done?

A. Immediately afterward, following at the same moment continuously.

X Q. 1033. What was your object in trying this experiment?

A. Mr. Sawyer had a theory somewhat similar to Mr. Edison's, as I have understood it, that a very high 'electrical resistance in the incandescent conductor would be highly advantageous and he was endeavoring to illustrate to me the effect of such a resistance by this crude experiment, and that was the object of the experiment.

X Q. 1034. I do not understand your answer. How did this experiment illustrate anything?

1328 A. Mr. Sawyer said that if he could get a conductor that would stand the "racket" as he called it, as fine as a hair or the smallest pencil line, it would be perfection for a conductor. I said to him that we could not get a current through it with any electro-motive force we had available or that would be safe. He insisted that it could be done and this led to the experiment.

X Q. 1035. Did he say what kind of a conductor?

A. I don't remember.

X Q. 1036. Was this experiment then merely to ascertain the electro-motive force of the machine?

A. No, it was to demonstrate that with the electro-motive force we had available and which was safe to use, we could send a current of sufficient strength through a very high resistance to heat it up to incandescence.

X Q. 1037. Did you expect to run this paper up to incandescence?

A. No, sir; Mr. Sawyer expected to run the plumbago up to incandescence.

X Q. 1038. Did he or you think that the first fine pencil line you made would become incandescent?

A. I don't know.

X Q. 1039. Now, as I understand, you kept adding plumbago to the paper and shortening the length of the line until you could get a current through; is that correct?

A. Yes.

X Q. 1040. Did you or he expect that when you reached a point where the current would pass through the plumbago it would become incandescent?

A. Yes.

X Q. 1041. What part did the paper play in this experiment, and would not any insulating substance, such as rubber, have answered the same purpose?

A. I think it would; the paper was a convenient article.

X Q. 1042. Was there then no special object in using the
1329 paper, other than as an insulating holder for the plumbago?

A. That was all.

X Q. 1043. Did this experiment inform you of anything or suggest anything?

A. Yes.

X Q. 1044. What?

A. It gave us some knowledge of the conductivity of the plumbago we were using, and we proceeded immediately to further experiments.

X Q. 1045. Was this the only suggestion or information you derived from this experiment?

A. Yes, I believe so. I don't recollect anything else.

X Q. 1046. How could you have learned of the conductivity of the plumbago you were using, without knowing the electro-motive force of your machine and the exact amount of plumbago placed upon the paper?

A. The only information we obtained was relative and not positive; we found that we could pass the current from that dynamo through a certain length and size of packed plumbago.

X Q. 1047. What now was the next thing that you did?

A. The paper being charred and burned in the last experiment and the line of plumbago broken so as to break electrical connection, we took a slip of paper, soft and porous, filled it with plumbago to the best extent we could, rubbed it with plumbago in a groove in a piece of iron with a burnisher, pressed it, put it on the desk with a sheet of mica underneath it and applied the electrical terminals.

X Q. 1048. What was your object in this?

A. We thought, in that way, possibly we might demonstrate what Mr. Sawyer had said in regard to high resistance, and that there was less liability of the breaking of the conductor and that we could continue to pass a current through it a longer time before it would be destroyed.

1330 X Q. 1049. What had Mr. Sawyer said in reference to high resistance that you expected this experiment would demonstrate?

A. I have already stated that before. I will repeat it if you desire; as I said, Mr. Sawyer had a theory that a very high-resistance conductor of small section, even as small as a hair or a pencil-mark would be highly advantageous if the conductor could be made to endure; on the other hand, I said that I did not think that such very high resistance would be advantageous and stated that no electro-motive force available to us or that would be safe, would pass a current of sufficient strength through such a conductor to make it incandescent; Mr. Sawyer contended to the contrary of my views and that a current could be passed through such a conductor to make it incandescent from the dynamo we were then using.

X Q. 1050. Now you could not have expected that this experiment could show anything in regard to the durability of such a conductor. I, therefore, infer that the object was to ascertain whether your machine would drive a current through it; am I correct?

A. Yes, a current of sufficient strength to make it incandescent.

X Q. 1051. In this experiment, as in the former was the paper used simply as a vehicle to hold the graphite?

A. Yes, as a holder of the graphite.

X Q. 1052. What information or suggestion did you gather from this experiment?

A. The conductor remained incandescent longer than we had anticipated, and when it finally broke, and broke the electrical connection, portions of the paper charred and condensed were left upon the mica, took fire and slowly burned up; we were in trouble about getting carbons for incandescent conductors and the thought occurred to both of us that we had possibly hit upon a way in which such carbons could be produced of the size and shape and 1331 resistance which we desired, if we could prevent the consumption of the paper; we therefore at once proceeded to further experiments.

X Q. 1053. In order that there may be no misunderstanding, had you at this time determined upon what size, shape and resistance of incandescent conductor you desired?

A. Only tentatively; we had been making conductors out of French carbons in straight pencils, working down the pencils to get them small; we had also been making carbons out of thin sheets of French carbon which we formed into an arch to rise above the holders of the lamps; we had great difficulty in working down these carbons to size and shape such as we were then trying to use.

X Q. 1054. I do not understand from your answer whether you had or had not determined what the size, shape and resistance of the incandescent conductor should be?

A. I have answered your question, it seems to me, as fully as I can; perhaps I should add that we were endeavoring to make our conductors as small as possible in section in accordance with Mr. Sawyer's theory of the advantages of high resistance; we certainly had not determined on any fixed resistance or any fixed size of conductor, and we were trying different shapes of conductors.

X Q. 1055. Am I then to understand that you saw in this way a possibility of overcoming the mechanical difficulty of getting a carbon of small size and of any desired shape?

A. Yes, that is what I mean to be understood; that is, we would avoid the difficult operation of shaping carbons, and sizing them, by shaping and sizing the material from which they were made.

X Q. 1056. Now at the time of these experiments, for I understand they were all on the same day, had you as yet made what you would call a lamp; I do not refer to rude experimental apparatus, such as chemical flasks with improvised holders and carbons, but a lamp mechanically constructed. 1332

A. I say yes. We had before then made some lamps, which, considering their cheapness and practicability, would be useful today, if the present improved lamps could not be obtained and in places where those lamps were not at hand for use.

X Q. 1057. If then you had at this time made lamps as you say, in view of your statement that you then "were in trouble about getting carbons for incandescent conductors," and "had been making conductors out of French carbons in straight pencils, working down the pencils to get them small," and "had also been making carbons out of thin sheets of French carbon," I infer that these experiments must have been made some time after you had been at work in Centre street. Am I correct?

A. We had been there for a little time, I cannot now remember how long, but it was after we had set up and tried a good many lamps.

X Q. 1058. Now let me recall your attention to the fact that you did not go to Centre street until the 7th of March, 1878, that no experiments had been conducted before you went to Centre street except the one at the coal and iron exchange. That when you went to Centre street you had no facilities, apparatus or tools for experimentation, but had to get them, that your working force in Centre street was limited to Sawyers, the elder and junior, to Kaeting and Sharp, that the working down of carbons or the making of lamps must have taken considerable time, and that the lighting machine which you say you used was in the basement of the building, and, if you remember, was only open to your use for a day or two after you went to Centre street. I call your attention to these facts with the view of refreshing your recollection as to the time of these experiments, for it seems to me that if the experiments which your answers would imply had been conducted, these particular experiments must have been made at a comparatively late day, or if they were performed immediately on your arrival they could not have been preceded by the amount of work your answers import? 1333

A. In answering at this day in regard to events taking place between eight and nine years since, I cannot hope to reach positive accuracy. My recollection accords with yours in regard to all the matters testified to, except the length of time during which Arnoux & Hochausen's lighting machine was in the basement. I think it was certainly while that machine was there that we tried the experiments I have related, and reviewing the subject in my own mind I cannot fix the time of these experiments within a few days after our going to Centre street, and before making these experiments we had certainly made a large number of conductors from the French carbon, and experienced the difficulty of which I spoke in their manufacture, and had exhausted, as I think now, all the stock of that kind of carbon, or nearly all, that we could get hold of. Therefore, I think that it was the fact that before these experiments we had made the lamps of which I have spoken. From other circumstances, it seems to me that these experiments took place soon after the agreement of the 19th of March, between Mr. Sawyer and myself. It may be that I am wrong in regard to the time of the arc-light machine being there, or it may have been that Arnoux & Hochausen, who were continually experimenting, took out the first machine and were experimenting with another one, or, they may have cut us off from the use of that machine for a while and then subsequently we used it, or it is barely possible, though I think it highly improbable, that these experiments took place earlier than I think.

Adjourned till Tuesday, 11th inst., at 1 p. m.

1334 TUESDAY, *Oct. 11th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

Witness says: I wish in this connection to call attention to my answers to cross-question 332 and cross-questions following to 400, in which it will appear that I had not endeavored to fix with any certainty the time during which the arc-lighting machine remained in ths basement.

X Q. 1059. Are you positive, however, that it was while the arc-lighting machine was in the basement and you had a current from it, that these experiments were performed?

A. No.

X Q. 1060. Are you positive that prior to the conduct of these particular experiments you had been making the carbons mentioned in your 1055th answer and had made lamps as stated in your 1058th answer?

A. I am as positive in regard to the carbons as I can be at this length of time and I am confident, but not positive, as to the lamps. It seems to me that I cannot be mistaken in regard to it; nevertheless, it is too long a time since then, unless some positive fact in regard to which the date could be definitely fixed should be brought to my attention, that I should be absolutely positive.

X Q. 1061. Can you remember what the first lamp was which was made in Centre St. By "lamp" I do not mean rude experimental apparatus, such as chemical flasks or a globe with improvised carbon supports and stoppers, but a mechanically and completely constructed lamp?

A. I do not recollect any one in particular, but of types of lamps I recollect the earlier or first ones. The globes were made 1335 of Florence flasks. The second kind, as I recollect it, were globes like Florence flasks with wider mouths and flanges which I got blown at the glass factory.

X Q. 1062. I want to make myself clearly understood. I assume that at some time there was made in Centre St. a lamp complete and mechanically constructed. If such a lamp was made, I assume it must have been made by some one, proper tools must have been employed, and as the making of this lamp must have necessitated the construction of special parts, few of which existed in trade and most of which must have been specially constructed, which parts must afterwards have been put together, and the lamp must have been either exhausted or charged, the entire work being done, I assume, under intelligent direction; moreover, for the making of these parts instructions, drawings and the like, must have been given. Now, do you not remember whether such a lamp was made, what its character and construction was, and by whom and where it was made?

A. The difficulty of your question is that you do not distinguish by proper words what you mean. The first lamps we made or caused to be made during the first week we were in Centre St. answered the description you give. They were intelligently planned by Mr. Sawyer and myself. We procured the glasses and caused the metal parts to be mechanically made, caused them to be set up or set them up ourselves and run. From that time forward, we made other and different lamps continuously, which answer your description, up to the time when we left 43 Centre St. in May or June. I cannot distinguish or tell the time, nor positively describe with accuracy the different kind of lamps nor the time of their production. You will see them pictured, or some of them, rudely, in the testimony of Mr. Church and possibly of Mr. Sawyer in the interference case. You have endeavored in this case to obtain an acquiescence from me, in the limiting of the number of persons engaged on the work of the lamps or their construction in 1336 parts to certain persons you have named, omitting all work done out of the shop by other parties, of which a large amount was done by different parties.

Answer objected to as irresponsive.

X Q. 1063. I am anxious to learn the facts in regard to the making of lamps in Centre street, by whom they were made, what their constructions were, where they were made, or your best recollection in regard to these things. Now, I have endeavored to explain what I meant by a lamp, and I shall endeavor to make myself clear. A Florence flask filled with an inert gas, with an improvised stopper, with rude conductors and carbon, I do not understand to be anything but experimental apparatus. A lamp could not have been a simple thing to make. The question of globe, base, holders for the carbon, connection of the carbon to the holders, adaptability for charging or exhausting, must have all entered into the construction of a lamp. If, in point of fact, such a lamp was made in Centre street, the first lamp, or if more than one were made, set of lamps, must have been the subject of discussion and explanation. Now, can you not remember the circumstances surrounding the making of such a lamp, or set of lamps, what its general character was, and what its parts were?

A. The very first lamps we made in Centre street with Florence flasks for globes answer your description of a lamp. They were intelligently planned for lamps, their parts adapted for all the purposes of which you speak, and more. They were lighted up and run as lamps. In answer to your desire expressed in the first part of your question, their parts were gathered together by purchase of the glasses, manufacture of the bases, cast and worked up at places and nicely finished with conductors insulated through the bases by appropriate insulation, with platinum tips for the holders of the carbon, and with an inert or carbon preservative gas as an atmosphere; part of the work being done by jewelers, part by instrument-makers, part in our own shops, part by Mr. Keating, 1337 part by Mr. Sharp, perhaps (I don't recollect whether he was there at first), and very probably parts by other parties assembled and put together in our shop, or in Mr. Sharp's place in Brooklyn, the whole being run by Mr. Sawyer and myself as electric lights, from that time forward; lamps, each perhaps an improvement in some particulars upon the other that had gone before it, were certainly made by and for us while at 43 Centre street, until we reached lamps that were satisfactory to us for the time being. Now, I have to say that I cannot give the time of any of these steps with any considerable degree of accuracy. I can give you the impression that remains in my mind, as to the time when we got lamps that were satisfactory to me and that I considered practical lamps.

Answer objected to as irresponsive.

X Q. 1064. As near as you now recollect you went to Centre street on the 7th of March, did you not?

A. 6th or 7th of March.

X Q. 1065. Do you bear in mind your testimony in regard to the fitting up of the rooms?

A. Generally; not in particular.

X Q. 1066. Do you remember the first time in 43 Centre street you ran a conductor to incandescence, the conductor being in a glass globe of some kind?

A. Yes.

X Q. 1067. Do you remember generally what the conductor was, what the globe was, and how the conductor was placed upon the conducting wires?

A. Yes.

X Q. 1068. You say you remember; now tell me what the incandescent conductor was; what the globe was and how the incandescent conductor was fastened to the wires.

A. The incandescent conductor was a pencil of gas-retort carbon or of French carbon; the glass was a Florence flask. The incandescent conductor was held between two metal supports in depressions made in the support by the pressure of the support against the ends of the conductor. 1338

X Q. 1069. Please make a drawing illustrative of the apparatus you have just described.

(Witness makes a sketch.) Same offered in evidence and marked Defendant's Exhibit "Man Sketch, October 11th, 1887."

X Q. 1070. What was the atmosphere in the flask?

A. Ordinary illuminating gas.

X Q. 1071. Who constructed this apparatus?

A. I don't recollect.

X Q. 1072. Was it constructed in your presence?

A. It was put together in my presence and Mr. Sawyer and I together bought the flasks.

X Q. 1073. What was the base of this apparatus?

A. It was of cast brass, one ring cemented to the Florence flask, and the other screwed upon that with an insulation through the base for one of the holders.

X Q. 1074. There appears to be two holders. Please state how these holders passed through or were attached to the base.

A. One of the holders was simply screwed down into the bottom of the base or cup on the inside; the other passed through a piece of hard rubber, screwed into the base and thus insulated from it, terminating in a binding screw. The other binding screw was fastened to the outside of the base. There were orifices in the base, with stop-cocks for passing the gas in and out of the lamp in charging it.

X Q. 1075. Now, who made this base with its binding posts and stop-cocks?

A. I don't know. Mr. Sawyer got it done. I presume I knew at the time.

X Q. 1076. Who furnished the instructions by which the mechanic made this base and its parts?

A. Mr. Sawyer had talked it over, made some rude sketches, Sawyer made more perfect ones, gave the instructions and employed the people to do the work. 1339

X Q. 1077. How long after the mechanic had the drawings, &c., did it take before the base and its parts were delivered to you?

A. I don't know. It was done before we went to Centre street.

X Q. 1078. About how long do you think it took to make?

A. I have no recollection definitely.

X Q. 1079. Well, with reference to the 6th or 7th of March, the time you went to Centre street, when was this base delivered to you and Mr. Sawyer.

A. Well, I think Mr. Sawyer had them. They had been delivered to him before we went to Centre street, or the evening before. A day or two before that, I bought the platinum for facing the holders.

X Q. 1080. You say "them;" was more than one base and its parts ordered?

A. There were six or eight of them.

X Q. 1081. The same in design and construction?

A. Yes, nearly, if not quite.

X Q. 1082. If they differed at all, do you now remember what the difference was?

A. Some one or two of these bases were not like the rest and were, I think, got up by old Mr. Sawyer; whether they were in addition to the six or eight that Mr. Wm. E. Sawyer got manufactured, or a part of them, I can't recollect.

X Q. 1083. You don't tell me that for which I inquire, to wit: the point of difference?

A. That I don't recollect. I don't know they were different.

X Q. 1084. You don't remember who made them; do you remember who paid for them?

1340 A. Yes, I paid for them, or gave the money to Mr. Sawyer to do so.

X Q. 1085. Well, which was it?

A. My impression is that I gave him the money to pay for them.

X Q. 1086. Now, have you any check, voucher, bill or memorandum of any kind that would show who made these bases and their parts, or which would aid you in remembering who made them?

A. No, sir.

X Q. 1087. You have spoken of platinum for facing the holders in your 1079th answer, which you say you bought; where did you buy it?

A. I don't recollect.

X Q. 1088. Now, platinum is not on sale everywhere and not an easy thing to purchase; does nothing occur to you that would enable you to remember where you bought it?

A. No; and, on the contrary, it is an easy thing to *thing to* purchase; it may be bought of almost any dealer in precious metals, and at almost any jeweler's shop.

X Q. 1089. Have you ever bought any before?

A. Yes.

X Q. 1090. More than one?

A. Yes, I think so.

X Q. 1091. Do you remember where you bought it?

A. No.

X Q. 1092. Do you remember whether you bought the platinum for facing the holders at the same place as you had bought the platinum previously?

A. No, I do not recollect.

X Q. 1093. Did you buy it in New York or Brooklyn?

A. I think I bought it in New York, but I don't recollect.

1341 X Q. 1094. Did you buy it personally or send some one for it?

A. I bought it personally.

X Q. 1095. Was it delivered to you personally at the place where you bought it, or was it sent to you?

A. It was delivered to me personally at the place where I bought it, and I gave it to Mr. Sawyer.

X Q. 1096. Do you remember what you paid for it?

A. I do not.

X Q. 1097. Can't you tell me about how much?

A. I cannot.

X Q. 1098. How much did you buy?

A. That I don't recollect.

X Q. 1099. Can't you tell about how much?

A. No.

X Q. 1100. Can't you give me any idea whatever as to how much you bought and how much you paid for it.

A. No, only that it was a very small quantity.

X Q. 1101. Well, did you pay as much as a thousand dollars or as little as ten dollars for it?

A. I did not pay either sum.

X Q. 1102. Do you think it was less than ten, or more?

A. If you ask my judgment of the amount I will give it to you.

X Q. 1103. Well, do so.

A. I should think two, three, or four dollars, possibly five.

X Q. 1104. What kind of store did you buy it in?

A. I don't recollect where I bought it, probably at a goldsmith's, or goldsmith supplies.

1342 X Q. 1105. Now, I understand you are positive that these metal bases and their parts were delivered before you went to Centre street, or on the first day you were there?

A. Yes, I think the day before; perhaps not all of them the day before.

X Q. 1106. What use was made of the platinum in these bases and their parts?

A. It was not used on the bases; it was cut up into small pieces, a little less than an eighth of an inch square or round, brazed to the inside face of the holders at their top end, and a small hole drilled or punched not quite through the platinum, to receive the ends of the carbon conductors.

X Q. 1107. Who did this work—the mechanic that made the bases?

A. No, I do not know the individual who did it, but some jeweler brazed the pieces to the copper holders.

X Q. 1108. Who was the jeweler?

A. I don't know; Mr. Sawyer got it done.

X Q. 1109. Were the holders taken to the jeweler before the entire base was made, or afterwards?

A. I do not know; it was probably after they were fitted to the bases.

X Q. 1110. Did you ever see the jeweler, or give him any instruction?

A. No, sir.

X Q. 1111. Who paid the jeweler?

A. I paid out for all the work.

X Q. 1112. Now, have you any bill, check, voucher, or memorandum that would either enable you to state who the jeweler was, or refresh your recollection as to who he the jeweler was, or refresh your recollection as to who he was?

A. I have lost my memoranda of those payments, or mislaid them so that I cannot find them.

X Q. 1113. Do you remember about what the bases and holders cost?

1343 A. I do not.

X Q. 1114. Now, I understand it was with these bases and holders, and with a Florence flask as a globe, that you ran your first conductor to incandescence in Centre street; am I right?

A. Yes.

X Q. 1115. How long was it before you either had made, or made other bases or holders than these?

A. I cannot recollect, but it was within a week, I think.

X Q. 1116. Then you think you used these, and only these, during the first week you were in Centre street?

A. No.

X Q. 1117. Defendant's Exhibit Man sketch shows a distinct type of apparatus with very carefully prepared base and holders, and this, I understand, was the first apparatus you used. Now, when did the first modification of, or departure from this apparatus take place, and what was the modification and departure?

A. Instead of the Florence flask we used a straight glass tube with a metal cap at either end, the conductors screwed into the metal caps on the inside, the caps cemented to the tube and the incandescent conductors extending from the end of one holder to the end of another.

X Q. 1118. Please illustrate by a sketch.

(Witness makes a sketch.) Same offered in evidence and marked Defendant's Exhibit Man Sketch No. 2, Oct. 11, 1887.

Adjourned till Wednesday, 12th inst., at 1 p. m.

1344 WEDNESDAY, *Oct. 12th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination — Mr. MAN proceeded as follows:

X Q. 1118½. In this sketch No. 2, how was the incandescent conductor attached to its supports?

A. It was stuck into one end of one support and the other support was pressed up against the other end, small holes or depressions being made in the ends of the supports to receive the ends of the carbons.

X Q. 1119. Were the brass caps used in this second apparatus, parts of the brass bases to which you have referred, or were they made specially for this second apparatus?

A. I think they were made specially.

X Q. 1120. When were they made—before you went to Centre street, or after?

A. I think afterwards.

X Q. 1121. Were they colored afterwards or before?

A. I cannot say.

X Q. 1122. Were they ordered after the first apparatus had been tried?

A. My impression is they were. I cannot positively say.

X Q. 1123. Is it then your best belief that they were ordered after the Exhibit No. 1 had been tried?

A. Yes.

X Q. 1124. In the apparatus shown in Exhibit No. 1 did you try other atmosphere than illuminating gas?

A. Yes.

X Q. 1125. Did you try a vacuum?

A. My impression is that we did; I am not positive.

X Q. 1126. Was it after you had experimented with the
1345 apparatus of Exhibit No. 1, employing as its atmosphere
something other than illuminating gas for exhausting chamber, that you ordered the parts for apparatus No. 2?

A. No, I should think not.

X Q. 1127. Do you — that the parts for Exhibit No. 2 were ordered before you had tried the apparatus of Exhibit No. 1 with an atmosphere other than illuminating gas?

A. Yes, I think they were.

X Q. 1128. What was the object, or what suggested the making of this apparatus in Exhibit No. 2?

A. I have no recollection, but from the difference between the two apparatus, it is evident that the second apparatus was made to avoid any insulation of the leads and conductors other than the glass of the tube or globe.

All after "recollection" defendant's counsel will move to strike out as incompetent.

X Q. 1129. I understand you then to argue that the object of making this second apparatus, as you state, was that you have no recollection now as to why you made it?

A. I make no argument upon the matter. I simply state that the apparatus itself shows the object sought in its construction.

X Q. 1130. The trouble is we have not got the apparatus; I understand you to remember what the apparatus was, but to have entirely forgotten why you made it?

A. My sketch shows the apparatus, and illustrates the point of avoidance of insulation of the conductors, or either of them, by any means other than the glass tube or globe.

X Q. 1131. And you therefore think this must have been its sole object, and you now have no recollection of its having been made for any other purpose?

A. That, I think, is correct.

X Q. 1132. Who made the brass caps and holders for this apparatus?

A. That I don't know.

1346 X Q. 1133. Were they made in the shop, No. 43 Centre street?

A. No, I think not.

X Q. 1134. Have you no recollection whatever as to who made them, or where they were made?

A. No.

X Q. 1135. Who gave the order or instructions to the mechanic who made them?.

A. I believe Mr. Sawyer did.

X Q. 1136. Who paid for them?

A. I paid for everything.

X Q. 1137. Did you pay directly or give Sawyer the money?

A. I don't know. The manner of payment of things was, either to hand Mr. Sawyer the money when he showed me the bills, or to send the money by a messenger with the bills to make payment. Sometimes and frequently Mr. Sawyer paid bills as the things were sent into the shop, made memorandum of the payments he made, and afterwards I gave him the money for them.

X Q. 1138. Have you any voucher, paper, receipt, check, or anything that would show or aid you in remembering by whom or where the caps and holders of the apparatus shown in this exhibit were made?

A. No.

X Q. 1139. Did these holders have platinum tips?

A. I think they did, but I am not certain.

X Q. 1140. The holders used in this apparatus were not, or were they, the holders of the first apparatus altered?

A. They were not, I think.

X Q. 1141. Who made the holders and put the platinum tips upon them?

A. I don't know; my impression is they were made at the shop.

1347 X Q. 1142. Now, as the caps and holders had to be specially made from drawings or instructions, can you tell me how long it was after they were ordered before they were delivered?

A. No; a very short time, however.

X Q. 1143. When you say "a very short time," what do you mean?

A. A day or two; or two or three days.

X Q. 1144. When did you get the glass tubes that were used in this exhibit?

A. My recollection is that it was a piece of a large glass tube about an inch and a quarter in diameter, which I had at my house: we cut it into two pieces, I think, at the shop.

X Q. 1145. The cap must have been made with reference to the size of the tube, must it not?

A. Yes, I think they were.

X Q. 1146. Was more than one apparatus of this kind made or did you order the parts for more than one?

A. Yes, we had two sets, but I don't think we ever used or set up but one.

X Q. 1147. What was the next departure or modification in the way of apparatus in which a conductor was run to incandescence?

A. I cannot pretend at this time to give the order with exactness in which different things were done. I remember getting from Haggarty Brothers in Platt street, some glass globes with a neck and flange at the bottom end, and with stoppers in them level with the flange, ground and fitted. These glass stoppers we ground or had ground more nicely by a glass-cutter in Chambers street, and I took them to a diamond-cutter in Ann street and had them perforated for the conductors. I think that this was the next thing after the Florence flasks and tube—I have mentioned calling the globes which I had blown over in Brooklyn in the shape of Florence flasks substantially, Florence flasks.

1348 X Q. 1148. You speak of globes you had blown over in Brooklyn. To what are you referring, globes used in Exhibit No. 1?

A. Yes, I have spoken of them before in this examination.

X Q. 1149. I was not aware that you had had special globes blown for the apparatus in Exhibit No. 1. Were these globes ordered before you went to Centre street?

A. No, I think not.

X Q. 1150. Were they ordered before or after the metallic bases of Exhibit No. 1 were ordered?

A. After.

X Q. 1151. After they were delivered?

A. Yes, after they had been delivered, and the lamps run.

X Q. 1152. These globes must have been made with reference to the size of the base, must they not?

A. Yes.

X Q. 1153. Did you take the base over to the glass-blower?

A. Yes; the ring of one of the bases.

X Q. 1154. Who was the glass-blower from whom you ordered these globes?

A. I can't remember his name. The factory was in First street, or the continuation of First street, east of South Fourth street; I may not get the names of the streets right, but that indicates the location; three or four blocks to the right, as you cross from New York, by South Seventh-street ferry.

X Q. 1155. Can you ascertain the exact situation of such factory, and if you can will you do so?

A. I cannot do so without going there specially. The factory is there; anybody can find it. It is or was a large glass factory.

1350 X Q. 1156. In your 1147th answer you have described the third form of apparatus used. Please illustrate the same by a sketch.

No 286.
E. Light Co.
v.
McK. Light Co.
p. 1349

(Witness makes a sketch.) Same offered in evidence, and marked Defendant's Exhibit Man Sketch No. 3, October 12, 1887.

(Here follows diagram marked p. 1349.)

X Q. 1157. Did you order from Haggarty Bros. more than one globe and stopper as shown in this Exhibit No. 3?

A. I bought them ready made.

X Q. 1158. Do I understand that they were articles in stock?

A. I found them there and bought them.

X Q. 1159. Do you know whether they were articles in stock or had been ordered for some special purpose?

A. I assume that they were articles in stock or articles like some that had been ordered from them. They were articles such as are used in the windows of shops to exhibit oils, seeds and chemicals.

X Q. 1160. Were they then like bottles that could stand on their ends and had a glass stopper fitted into a flange and which could be inserted and removed?

A. Yes; except that I don't know that they had glass stoppers fitted to them; I think they had not when I bought them.

X Q. 1161. How many did you buy?

A. Three or four.

X Q. 1162. In your 1148th answer you say you ground or had ground the glass stoppers more nicely by a glass-cutter in Chambers street. What is your recollection, that they were ground by you in Centre street, or had them ground by the glass-cutter in Chambers street?

A. We had them ground by the glass-cutter I have mentioned.

X Q. 1163. So as to make a better fit?

A. Yes.

1351 X Q. 1164. Who was the glass-cutter?

A. I don't know his name. His place was on the right side of Chambers street going east, a little way from Chatham street—a block or two.

X Q. 1165. Did you take them to the glass-cutter?

A. Yes.

X Q. 1166. How did you find him, by looking up at the signs, or were you sent to him?

A. No; somebody told me of him.

X Q. 1167. Do you remember who told you about him?

A. No.

X Q. 1168. Who was the diamond-cutter in Ann street?

A. I don't know his name.

X Q. 1169. Whereabouts in Ann street was his place?

A. On the right-hand side going from Nassau to William, up four or five flights of stairs.

X Q. 1170. How did you find this diamond-cutter? By looking at signs, or were you sent to him?

A. I found him out by inquiring among the jewelers.

X Q. 1171. Did you buy these bottles and stoppers, take them to the glass-cutter and have them cut by the diamond-cutter the same day?

A. No, I think not. I bought them and took them to the glass-cutter, I think, in the afternoon of one day, and the next morning took the stoppers to the diamond-cutter and got the stoppers from the diamond-cutter the same day I took them there. The diamond-cutter had done work for me before. I did not find him out for this work.

X Q. 1172. You say this diamond-cutter had worked for you before. Now can't you tell me his name?

A. No; he was perhaps more properly a lapidary than a diamond-cutter.

1352 X Q. 1173. I presume you must have had the holes cut through the base with reference to the size of the tubes or conductors passing through the base?

A. No; I think we adapted the conductors to the holes, the holes being all of one size and about three-thirty-seconds of an inch, as I recollect it. The leading-in conductors were hollow.

X Q. 1174. What supports for the carbons did you use in this apparatus? and who made the tubes and stop-cocks?

A. I don't remember any stop-cocks in connection with it. The conductors were tubular, flattened together at the upper end and brazed, with an orifice below the flattened portion. We may have had stop-cocks on them, but I think not. I think we pressed them together and soldered them up. The carbons were held at first, as in the first lamp I mentioned, by the spring of the conductors. We bought pieces of tubing, threaded them, put nuts on them, and did the work in the shop. We afterwards modified the manner of holding of carbons, both in these lamps and in the ones I first described.

X Q. 1175. Do I understand that all the metallic work of this apparatus was made in 43 Centre street?

A. Yes, I think so; there was not much of it.

X Q. 1176. Who did the mechanical work?

A. I think old Mr. Sawyer did it.

X Q. 1177. Where did you get the tubing?

A. At Frasse's, I think. He has two places. I cannot tell which it was; we bought things at both. One was in Fulton street, the other was in Chatham.

X Q. 1178. What kind of tubing was it?

A. Brass tubing in stock, all sizes.

X Q. 1179. Now, in apparatus No. 3, none of the parts of the previous apparatus, as I understand, were used?

A. None, unless the carbons.

1353 X Q. 1180. What was the object or design of this third form of apparatus?

A. To obtain a better sealed chamber of glass than with the brass caps, and avoid insulating either of the leading-in conductors otherwise than by the glass through which they passed. The form of the stopper and neck, in which it was placed, enabled us to cover the whole with sealing wax, which we did. Another object was to avoid separation of the parts by unequal contraction or expansion by heat, by making them all of glass.

X Q. 1181. What was the next form of apparatus used in your experiments at 43 Centre street?

A. A slight modification of this by closing up one of the tubes of the leading-in conductors at the lower end, leaving only one opening into the lamp. This was to enable us to charge the lamp by first exhausting and then allowing the gas to flow into the exhausting lamp, the open tube being branched outside of the lamp and fitted with stop-cocks for that purpose.

X Q. 1182. How many separate and entire apparatus of the kind shown in Exhibit No. 3 were made?

A. I think, of that exact kind, only three or four.

X Q. 1183. What was the next apparatus in which a conductor was run to incande*n*scence at No. 43 Centre street?

A. Another modification of this last, which consisted in using iron wire for conductors, with a shoulder coming down upon the glass stopper inside the lamp, accurately fitted to the hole in the stopper, and with nuts at the lower side of the stopper, and one of the conductors was drilled out at the lower end to make it a tube opening to the air, and a hole drilled into this tube on the side of the conductor in the lamp.

X Q. 1184. Did you use for this modification globes and stoppers bought at Haggerty's?

1354 A. Some of them, and some of them we broke and bought others.

X Q. 1185. Were the others of the same kind, and procured at the same place?

A. No; I think I bought all Haggerty had the first time, and I got others, but I don't remember where.

X Q. 1186. Did you have the stoppers for these new bottles reground and holes drilled in them?

A. No; I think they were of smaller size in the neck and we had the same stoppers, so far as they were not broken, reground into the new bottles.

X Q. 1187. Who did this regrinding?

A. This same man in Chambers street. I also got new stoppers for some that were broken and had them perforated by the same lapidary.

X Q. 1188. Who did the work in the metallic work on this modification?

A. I think old Mr. Sawyer. I have no definite recollection. It might have been he or Mr. Sharp.

X Q. 1189. What was the next form of apparatus?

A. Still another modification of this, in having the glass stoppers shouldered so that the shoulder would rest on the end of the neck of the bottle, so that atmospheric pressure when the atmosphere was exhausted from the bottle or globe would not force in the stopper and split the neck of the bottle.

X Q. 1190. These stoppers with shoulders must have, as I infer, been specially made. Who made them?

A. The same glass grinder or cutter in Chambers street.

X Q. 1191. You must also, I take it, have bought new stoppers?

A. We only made one of them, as I recollect; it may have been two, at most three.

X Q. 1192. These stoppers must also have had holes cut in them for the leading-in tubes; who cut them?

1355 A. The same lapidary perforated this stopper.

X Q. 1193. What was the next modification?

A. To use a plate of glass perforated for the conductors and ground and fitted to the flange of the globe, or bottle as you call it, instead of the stopper.

X Q. 1194. Was the plate of glass especially made and ground?

A. No, not at first; we used pieces of plate glass for the purpose, and ground them with the flange until they were fitted tight.

X Q. 1195. Who made the perforations in the plate glass for the conductors?

A. We made them ourselves.

X Q. 1196. In what way?

A. In a lathe revolving a drill made of a copper tube, and using emery.

X Q. 1197. Who did this work?

A. Some Mr. Sharp did, and some old Mr. Sawyer did; some of it I did myself.

Adjourned until Thursday, the 13th inst., at 1 p. m.

1356 THURSDAY, *13th October*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1198. Was this work done in your shop at 43 Centre street?

A. Yes.

X Q. 1199. How many of such pieces of plate glass were so ground and perforated?

A. I think all our bases which we used on our lamps at 43 Centre street were made of plate glass, but I may be mistaken in this, and it may be that some of them were blown in moulds while we were there. My recollection in regard to the matter is not distinct, and, therefore, I cannot state the number; we had several dozens of them perforated by Mr. Sharp at his shop in Brooklyn; they were of different sizes.

X Q. 1200. You have not understood my question; in Exhibit No. 3, as one of its modifications, you have said the glass globe or bottle was placed upon a piece of plate glass, holes or perforations being made in the plate glass; what I wish to know is, how many pieces of plate glass were perforated for this specific modification of the apparatus referred to?

A. I think only three, or at most four.

X Q. 1201. Have you described all the modifications made up to this time, in the apparatus referred to in Exhibit- 1, 2, and 3?

A. No, I have latterly followed out the modifications in the glass simultaneously, and other modifications were made in the holders of the incandescent burners.

X Q. 1202. Well, what were those modifications?

1357 A. The metal tops of the holders were cut off and pieces of carbon rod, in some cases square, and in some round, were substituted for the metal tops of the holders; at first these were fastened to the leading-in conductors by being wired to them, afterwards by drilling the metal tops of the holders and inserting the rods of carbon into the hole thus drilled in the metal, so that the carbon tops of the holders extended above the metal of the leads or leading-in conductors. At first the carbons of the incandescent conductor were inserted at their ends in pits drilled in the carbon-holder, that is, the opposing faces of the carbon-holders had depressions in them in which the ends of the incandescent conductor which extended between them were inserted, thus supporting the incandescent conductors. Afterwards a groove was made across the top of the carbon-holders sufficiently deep to receive the incandescent conductor, which was laid in this groove across the tops of the two holders and packed in with powdered carbon; with this form of holders carbons of an arch shape were used, rising above the tops of the holders; a modification of the tops of the holders was also made, omitting the grooves just mentioned and making grooves in the tops of the holders at right angles to those last mentioned, to receive the ends of flat arch-shaped conductors.

Another modification was made in the tops of the conductors by omitting the grooves and filing notches out of the inside tops of the opposing conductors to receive flat arch-shaped conductors.

Another modification was to split the tops of the carbon-conductors to a depth of about three-quarters of an inch, more or less, cut off one side of the top of each conductor, drill through the remaining portion of the top and the piece cut off, insert in the drill-hole a small bolt with a nut, so that the piece cut off could be used with a bolt and nut as a clamp for holding the ends of the conductors.

Where straight round pencils of carbon were used for the
1358 incandescent conductor, the parts were clamped together and
holes drilled in the slit close to the tops of the conductors a little less in diameter than the carbon pencils, so that they could be clamped in the conductors by tightening the screw-bolts, thus, as shown by Fig. 4 and Fig. 4 (A) of Exhibit 3, which figures I have just drawn on said exhibit.

Another modification, where other than ordinary illuminating gas was used as an atmosphere, was to first run the incandescent conductors after being placed in the holders, and after the whole interior works of the lamp were set upon the plate-glass base—was to run these conductors up to the high incandescence in an atmosphere of hydrocarbon, usually illuminating gas, first to heat the conductors, and second, by deposit of carbon, to perfect their electrical connection with the holders, then to take off the globe of the lamp, leaving the works all attached to the glass base, and cleanse and purify all the parts, including the globe, set them up in the globe again and charge the lamps with the atmosphere or vacuum we wished to use.

Still another modification was the introduction of spirally wound leading-in conductors, the convolutions of one conductor laying between the convolutions of the other conductor, making a double spiral tube, with short, straight ends to the conductors, which passed through the glass bases of the lamp, and short, straight ends at the tops electrically connected with the carbon holders of the incandescent conductors, the tops of the spiral conductors being held in place by a clamp electrically insulated from them. Following this clamp was the diaphragm of soapstone or other insulating material shown in our first lamp patent, at first used for the same purpose of supporting and clamping the spirally formed leading-in conductors. At the same time that we were using and setting up the Florence flask and seed vessels, or sample holders for globes I procured from Mr. Hahn, a glass-blower in North William street, near Chatham, several straight glass tubes closed at one end and 1359 open and with flanges at the other end. These were used simultaneously as globes for our lamps with the Florence flasks and with the seed bottles or sample holders, using with them plate-glass bottoms perforated as I have described. Simultaneously with the introduction of the plate-glass bottoms, were introduced metal clamps to fasten the globes and plate-glass bottoms together. Several modifications of these clamps were used, finally resulting in metal rings, one above the flange of the globe and one below the plate-glass bottom, through which screws were passed outside of the flanges and plate glass, to fasten them together. In cases where the tops of the globes were larger than the diameter of their flanges, the upper ring above the flange was made in two parts overlapping one another and halved together, so that they could be put upon the flanges and make one continuous ring, when applied and screwed down to the lower ring. Now, I have spoken only of the apparatus of the lamp.

X Q. 1203. Were all those modifications which you have rehearsed at such length performed with the Florence flasks, purchased on the day you went to Centre street, and the three or four seed bottles purchased at the time you have mentioned?

A. All the apparatus which I have mentioned was made and modified, as I have stated, while we had in use Florence flasks and seed bottles, so-called, as globes for our lamps, and while we had in use at the same time we had in use for globes for our lamps the tubular globes which I bought from Mr. Hahn, as I have stated, and while we had in use globes which I procured to be blown at two glass factories in Williamsburg, Brooklyn. We had all four kinds of globes, which I have mentioned, and also Florence flask globes, or globes of the general shape of Florence flasks which I had blown at the glass factory I have mentioned in Brooklyn, all at the same time.

1360 X Q. 1204. When we adjourned yesterday, as I understood, the only globes you had referred to were the Florence flasks, bought by you on the day you went to Centre street, the piece of tubing you brought over from your house, which was used in the second exhibit, the three or four seed bottles that you bought at Haggerty's, and the others referred to in your 1188th answer, and a few globes like Florence flasks, which you had made at the glass-house in Williamsburg the only stoppers, were those ground by the glass grinder or cutter, whose name and place of business you have forgotten, and which were perforated by the diamond-cutter or lapidary to whom you referred. You also mentioned that you yourselves cut holes in a piece of plate glass as a base. The only metal parts you had got were those bases and parts you had ordered before you went to Centre street, and the caps and holders for the apparatus of the second exhibit which were made for you. Now, in the numerous experiments to which you have referred in your answer to the 1202nd cross-question, were none other than these globes and bases or caps used?

A. I have already stated that glass bases were used. No other metal bases like those we ordered before we went to Centre street were used, at least not to my present recollection; but other globes than those that I mentioned yesterday, and other than any I have mentioned to-day, were used by us while the modifications and changes I have mentioned were being made, and while still the Florence flask lamps and the seed-vessel globes were being made by us.

X Q. 1205. What I would like to know is, whether any metal base other than those made by you before you went to Centre street, or made after you went there for the apparatus of the second exhibit, were used in the series of experiments mentioned in your answer to the 1202nd question?

1361 A. I do not recollect any others until outside metal covers, spun caps, for the whole base of the lamp were used by us, and these were later on.

X Q. 1206. Did you use other glass stoppers or bases than these few you have described? I understood you only to have referred up to the present to the stoppers ground by the glass-cutter in Chambers street, and perforated by the lapidary in Ann street, on the one occasion you went to these places, some pieces of glass perforated by Mr. Sharp, and the pieces of plate glass which you yourselves perforated and ground, by rubbing the flask or bottle upon the glass, it first being powdered with emery?

A. I will state the fact, and if I have not stated it before, or have not made myself clear, this will be a correction. At first we got a few pieces of plate glass, some of them cut in circles, and some square. We perforated, or got perforated for the conductors, one of these. We ground the face of the flange on one of the seed bottles, on a lap or face plate, with emery, to make it level and true, until we got it substantially polished. The plate glass was already true and polished. We then ground the flange and plate glass together until their junction was air-tight. We then set up a lamp upon it—the internal parts of a lamp. After this we got more pieces of plate glass at different times. We perforated and ground some of them ourselves, and Mr. Sharp perforated and ground a large number of them at different times for us. There were only comparatively a few of them used upon the seed-vessel lamps, so called; a much larger number being used upon globes of other forms, such as the tubes I got from Mr. Hahn, like big test tubes, and other globes of which I have not yet given an enumeration.

Adjourned till Friday, the 14th inst., at 10 a. m.

1362 FRIDAY, *Oct. 14th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN proceeded as follows:

X Q. 1207. What are the globes to which you last referred and where were they bought?

A. I got them blown at two glass factories I have mentioned in the eastern district of Brooklyn, Williamsburg. They were like the tubes I bought of Hahn with a flange at the bottom, open at the bottom, parallel sides rising from the flange and a bulb blown at the upper end which was closed. They were similar in shape to a broken globe, an exhibit in this case heretofore introduced and marked "Exhibit No. 29, globe of lamp produced by Albon Man, April 15th, 1887."

X Q. 1208. How many about of these were bought?

A. I can't tell; I have no distinct recollection in regard to numbers. It was a large number, I think more than a hundred; I can't be certain. At first, a few only, and afterwards more and more.

X Q. 1209. These were specially ordered, as I understand?

A. Yes, and they were of varying proportions and sizes and shapes, but the Exhibit Broken Globe is a type of them.

X Q. 1210 Am I correct in understanding, that in all the apparatus to which we have been referring the incandescent conductor extended across, from or near the tops of two parallel supports or leads, running perpendicular to the base of the lamp, as shown in substance in Exhibit No. 3?

1363 A. Yes, as shown in substance in Exhibit No. 3, but in this exhibit the incandescent conductor is shown as extending straight across from one holder to the other; in some of our lamps of this type this conductor was of an arched or circular form rising above the tops of the holders.

X Q. 1211. Now as I understand, before you went to Centre street you ordered in the neighborhood of ten metal bases which had been delivered on the 6th or 7th of March, and that you, on the same day or evening of the day previous, bought between half a dozen and a dozen Florence flasks to use as globes with these caps, and that you also had had made the supports or holders for the conductor, so that on the first day or two after going to Centre street you had these parts ready to assemble?

A. Yes, we bought the globes on the evening previous and we had the parts all ready to assemble when we went there.

X Q. 1212. Did you have any carbon conductors ready to put in these parts?

A. Yes.

X Q. 1213. Conductors made previously to going to Centre street, or after you were there?

A. I think the conductors were bought by Mr. Sawyer before we went to Centre street, but it may have been on the morning of the day we went there.

X Q. 1214. Did you put these parts together on the first day and run the conductors to incandescence?

A. Yes, Mr. Sawyer and his father did, and I was present when the current was turned on to the lamps.

X Q. 1215. Was more than one so-called lamp made that day and run to incandescence?

A. Yes, six or eight of them; as many as Mr. Sawyer and his father could get ready were lighted up.

X Q. 1216. What atmosphere was used on this day?

A. Simply illuminating gas.

X Q. 1217. What was the kind of carbon used on this first day?

1364 A. Small pencils cut from rods of French carbon about the diameter of the smallest knitting needles, perhaps less than that; rods of that diameter.

X Q. 1218. And these, as I understand, had been cut to the desired size so as to be adapted to the other parts of the lamp which had been previously ordered, and that all that you had to do on this day was to put the parts together?

A. The carbons were already of the desired diameter and only required to be cut off of the length we wished to use; and the ends were cut, smoothed off. I think this cutting off was done by Mr. Sawyer as the lamps were set up.

X Q. 1219. Will you please describe the construction and material for the supports for the carbons? I mean the leads in this apparatus.

A. They were made of copper rods, screw-threaded at the lower end; were attached to the base and hammered out flat at the upper ends and filed off to be of the same width after hammering flat as the diameter of the copper rods. One was simply screwed into the inside of the base, the other passed through an insulation in the base, had a hole through it in which to insert the electrical connecting wire outside the base with, I think, a binding screw to hold the wire. They were between a quarter of an inch and half an inch in diameter and the flattened part at the upper ends was about an eighth of an inch or less in thickness; I have mentioned the facing of these leading-in conductors with platinum at the points where they held the ends of the incandescent conductors; I think this platinum facing was not on the first holders that we used, but was put on almost immediately after first using them; these leading-in conductors or holders were about six inches in length inside the globe.

X Q. 1220. How long did you use these apparatus before any change whatever was made in the construction of the caps, carbons or holders?

A. I cannot recollect how long; I think the first change 1365 we introduced in that kind of apparatus was the facing of holders with platinum; this was done almost immediately, in a day or two.

X Q. 1221. With the exception of the facing the supports with platinum, did you try these apparatus without change of any kind for two or three days?

A. Yes, I think so, and longer, but am not certain.

X Q. 1222. In running these conductors to incandescence did you use the arc-light machine in the basement?

A. Yes.

X Q 1223. What trials, tests or experiments did you make to ascertain the efficiency of these apparatus and their parts, and what did you conclude from these tests?

A. We lighted them up and at first the carbons soon fell out of the holders. We discovered that the copper holder was fused where it touched the incandescent conductor. We, therefore, faced them with platinum which only melts at a very high heat. After we had done so, we discovered that a deposit of carbon was being made upon the incandescent conductors from the hydrocarbon gas, at first hard and dense, and as the deposit went on and the incandescent conductors increased in size their resistance was decreased, and the deposit became sooty and loose, and grew rapidly to such a size that the carbons were no longer luminous. We coupled them up in series, and in single multiple arc and in multiple-arc series, to see which was the best method of coupling with the current we were using. I do not now recollect anything else. Yes, I do recollect something else. The dynamo was run from an engine, driving all the machinery in a very large building. It was driven faster or slower, as more or less work was done in different parts of the building, and we discovered that its electro-motive force was very variable, and that some regulation was needed. We discovered that the electrical connection between the holders and the incandescent carbons was not suitable, and that with the variable electro-
1366 motive force of the dynamo machine an electric arc was liable to form at the points of junction between the incandescent conductors and the holders, by which the holders were fused and the carbons dropped out.

X Q. 1224. Was this last before you had the holders faced with platinum?

A. Both before and after.

X Q. 1225. Do I understand then that the first defect in the construction of the apparatus you ascertained was the heating of the copper holders at the point where the carbon was inserted in them?

A. Yes, that was the first, I think.

X Q. 1226. And to obviate that you had the holders faced with platinum?

A. Yes.

X Q. 1227. Now, about how long from the time you first run the lamp did you notice this defect and determine to try the facing of the holders with platinum?

A. I think it was the first day we run them. It was almost immediately, I think, after we commenced lighting the lamps.

X Q. 1228. As I understand you, then you went out and got some platinum and had the holders faced. Did you use the same holders as had held the conductor when incandescent, or did you get new ones made?

A. Used the same holders.

X Q. 1229. Who was it that faced the holders with platinum?

A. I have already told you that I don't know.

X Q. 1230. In what form did you buy the platinum?

A. I do not remember; either in wire or a straight flat strip, I think.

X Q. 1231. About how long was it before you received the holders, tipped with the platinum, and put them in the apparatus?

A. I cannot tell. My best judgment in regard to the
1367 thing is, that perhaps only one pair of holders was first tipped
with platinum, and afterwards the others. Looking back upon the matter now, I should think that we had one or more pairs of holders tipped and put to use the next day after we got there, but it would not surprise me if told by some one who absolutely knew, that it was several day- or a week; I do not think it was as long.

X Q. 1232. It was Sawyer that got the holders tipped with platinum, was it not, or was it yourself?

A. I think it was Sawyer.

X Q. 1233. As I understand, you found that the platinum also heated and fused?

A. Yes.

X Q. 1234. What did you then do to correct this defect?

A. We introduced a side circuit, or circuits with a switch, to turn more or less resistance into the side circuit, so as to turn more or less of the current into the lamps, and in some measure compensate for, or regulate the variable current coming from the dynamo, so that we would not get in the lamps at any time a current sufficient to fuse the platinum of the holders, or establish electric arcs between the holders and the carbon.

X Q. 1235. Did this have the desired effect?

A. Only partially, as it was not automatic.

X Q. 1236. This endeavor was not in improvement of the apparatus, but in the regulation of current; what did you next do in the way of alteration of parts, or modification of parts, to overcome the arc of heating at points of contact between the carbon and the holders?

A. I cannot at this length of time pretend to give with accuracy in their regular order of series, the different things that we did, and I wish to be understood in all my answers in that way. I give the next thing that now occurs to my mind. We cut off the metal tops of the holders, and substituted for the metal, carbon tops

1368 X Q. 1237. Were the lamps required to be run any time
to ascertain this heating of the holder at the points of contact with the carbon?

A. I think we discovered it almost at first.

X Q. 1238. Was a day, or two or three days required to convince you?

A. I think it was the first day.

X Q. 1239. As near as you now remember, how many days was it after going to Centre street that you tried putting carbon tops on the supports?

A. I can't tell.

X Q. 1240. Can't you tell me about?

A. I can only guess at it; I guess, a week, or more.

X Q. 1241. During the time that you were trying this first apparatus, and endeavoring to overcome the heating of the points of contact of the carbon at the holders, by trying platinum, and before trying the carbon tops, were you experimenting with other parts of the apparatus, the globes, bases, atmospheres or carbon?

A. Yes, I think we were.

X Q. 1242. Please tell me what parts you were experimenting with, what defects you had noticed, and how you endeavored to overcome them. I am referring to a period anterior to the time of the carbon tops.

A. We discovered in a day or two that the sealing of the lamps was defective. Leaving them standing over night charged with illuminating gas or hydrogen gas, I forget which, the current was turned on the next day upon one of the lamps, or more, and they exploded, showing plainly that they had taken in atmospheric air, which mixed with the atmosphere with which the lamp was charged, formed an explosive mixture, showing that the lamps leaked. This necessitated our frequently and continually renewing the atmosphere of the lamp, recharging it. The Florence flasks were too thin at their necks to be ground for stoppers; we
therefore got the seed vessels of which I have spoken,
1369 which were thick enough to be ground for glass stoppers,
as I have already described; we endeavored to remedy the production of the arc by inserting the ends of the carbon more deeply in the holders, and we endeavored to form a deposit of carbon at the ends of the incandescent conductors, to make better electrical connection between them and the holders. We packed around the ends of the incandescent conductors in the holders powdered carbon in a paste to make better connection; we enlarged the ends of the incandescent conductors by using larger carbon rods to make them, and working them down small between the enlarged ends; it is impossible for me to distinguish the globes or vessels in which these things were first done. I know we did them in the Florence flask which we first had and afterwards bought, or in some of the Florence flask-shaped globes which I had blown in the glass factory in Brooklyn, a sample of which I now produce; it is altogether probable, too, that some of these things were done, and I think they were, in the seed vessel globes I have mentioned. In this period anterior to the carbon tops we were endeavoring to get a better sealed lamp in the manner I have described; we were also endeavoring at the same time to get a better atmosphere for our lamps; we first used hydrogen for this purpose and next nitrogen;

we also pumped the lamps out before sealing them when filled with hydrocarbon or illuminating gas, to prevent the rapid deposit upon the incandescent carbons.

Adjourned till Monday, the 17th inst., at 1 p. m.

1370 MONDAY, *Oct. 17th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAX was continued as follows:

X Q. 1243. Is it your present recollection that while using the metal caps and apparatus of Exhibit No. 1, and before the glass stoppers were tried, instead of the caps, you deposited carbon around the ends of the incandescent conductor, or packed powdered carbon in a paste around the ends, or enlarged the ends of the carbon, as described in your last answer?

A. I think so, but at this length of time I cannot be positive in regard — it, except as to the deposit and enlarged ends; I feel confident that those things were done in the Florence flask lamps with the metal bases.

X Q. 1244. Is it also your recollection that while using the flasks and metal bases of Exhibit No. 1, and before the use of the glass stoppers, you had tried in the lamps of the flasks and metal bases, atmospheres of nitrogen and hydrogen and had also exhausted them with an air pump?

A. It is, according to the best of my recollection in regard to the matter, and I cannot pretend to be positive in regard to it at such a length of time, that before getting globes with glass stoppers we had exhausted the lamps, or partially so, by an air pump and had used the atmosphere of hydrogen. I cannot remember the order of events well enough to say whether or not we used nitrogen up to the time we got the lamps with glass stoppers.

X Q. 1245. Then while still using the Florence flasks and metal bases of Exhibit No. 1, and before trying the glass stoppers, it is your present recollection that you had an air pump, or the use of one, and had obtained or made hydrogen?

1371 A. Yes.

X Q. 1246. With these flasks and metal bases and before glass stoppers were used or tried, did you try different kinds of carbon?

A. I don't recollect any; we may have done so; I think only the one kind of carbon; I recollect we used more than one kind with the first apparatus; we got some lead-pencil leads and baked them, and used, or tried to use, some of them.

X Q. 1247. Was the object of trying the glass stoppers, instead of the metallic bases, to obtain an apparatus which would better preserve the atmosphere of the lamp?

A. Yes; it could be better sealed up and better insulation of the wires from each other was obtained for the leading-in conductors.

X Q. 1248. When these glass stoppers were tried I also understand the supports or leads, as you call them, were made hollow and were used for exhausting or charging the globes?

A. Yes, with various modifications; this was first done in globes of that kind.

X Q. 1249. With the use, then, of the glass stoppers, I understand, three objects were had in view: one an apparatus better adapted for the preservation of the atmosphere within the chamber; two, the insulation from each other by the structure of the apparatus itself of the leads or supports; three, the use of these leads or supports in charging or filling the globe by having them hollow?

A. Yes, those are the salient points.

X Q. 1250. So far as the carbon itself was concerned, or the means of attaching the carbon to the supports, these points were independent of the other features of the apparatus of either Exhibit 1 or 3?

A. Yes, we might improve the interior works of the lamp and the incandescent conductor, using either.

1372 X Q. 1251. Do you remember whether you had succeeded in so attaching the incandescent conductor to the leads as that an arc would be prevented in the flask and metal base lamps, and before trying the glass stoppers?

A. You refer to the arcs at the ends of the incandescent conductors. Both kinds of these lamps were being run while this matter still troubled us. We did not consider it altogether due to the lamps, but to the want of regularity in the currents, and we had not got, up to the time of getting the glass stoppers, a regular current or a means of regulation sufficient to prevent this trouble; nor had we remedied it completely in any other way.

X Q. 1252. In the lamp of Exhibit No. 1 of the flasks and metal bases, had you found difficulty in insulating or preserving the insulation between the supports and the metal base?

A. Only mechanical, and the difficulty of sealing up due to the construction. It was a complexity of structure which we desired to avoid.

X Q. 1253. Now, in this apparatus of Exhibit No. 1 of the flasks and metal bases, you discovered, as I understand, two defects—one. the arcing at the point of contact of the carbons and the holders; and two, the difficulty to preserve an atmosphere. Was this apparatus sufficiently good as a lamp to enable you to make any tests of the relative efficiency of different gases as an atmosphere or the use of a vacuum?

A. Yes.

X Q. 1254. Did you make such tests?

A. Yes.

X Q. 1255. What were the tests?

A. We first used hydrocarbon gas—ordinary illuminating gas from the gas main. With such gas, I have explained that the deposit of carbon soon prevented the incandescence of the incandescent carbon. By pumping them out or exhausting them, we 1373 found that the incandescence was much longer preserved, but that with the vacuum we got, the atmosphere was still not appropriate. We next used hydrogen gas, because we had not nitrogen, and found it better than the hydrocarbon gas. We next, in these lamps, used nitrogen gas, and found it the best. We exhausted our lamps with all three kinds of the gas. We found that there was danger of explosion with the hydrogen and hydrocarbon gas. Perhaps it would be better to say that we knew this before, and found that there was danger of leaking, by which the explosive mixture would be formed. This, of course, did not exist with the nitrogen gas.

X Q. 1256. Did you ascertain these results by taking different apparatus of the character of Exhibit No. 1 and running them under the same conditions—that is, the same current, same carbons, same methods of attachment between carbons and leads, same leads, same forms of globes and bases, same methods of attachment between globes and bases, but different atmospheres or gases, including a vacuum?

A. With the hydrocarbon gas we set up all the lamps; charged them all with hydrocarbon gas; exhausted some; we run them all with the same current. The test for hydrogen gas was made by charging the same lamp with hydrogen instead of hydrocarbon and running them by the current and observing that no deposit was formed; the same with the nitrogen. I don't think we discovered any particular difference in these lamps charged with a hydrogen or nitrogen atmosphere, whether they were exhausted or not. We may have done so; but if so, I do not recollect it.

X Q. 1257. While, then, you did not determine in this apparatus what the most efficient atmosphere was, you did ascertain that these metal bases were not adapted to the preservation of any atmosphere?

A. We discovered that the construction was not suitable
1374 to the permanent preservation of any atmosphere, and we
proved that certain atmospheres were unsuitable, to wit,
hydrocarbon.

X Q. 1258. What was the longest time you succeeded in running at continuous incandescence a conductor in the apparatus of Exhibit No. 1?

A. That I cannot recollect; I kept no memoranda of it. I can only say that people came in to see the lamps, stopped there and watched their running as long as they wanted to, and then the lamps were put out.

X Q. 1259. Do you know of one ever having run at continuous incandescence as long as ten minutes?

A. Yes, and very much longer.

X Q. 1260. As long as an hour?

A. Yes; I think longer than two or three hours.

X Q. 1261. Did you ever make, while at 43 Centre street, a lamp containing the different parts described and shown in letters patent 205,144?

A. In detail exactly like that?

X Q. 1262. Yes.

A. I do not know; in detail similar to that, yes.

X Q. 1263. What parts in this lamp are you doubtful about being in the lamp substantially like the description in this patent?

A. I do not know that any part was omitted; if any, the part G, and I know that lamps were built by us there with the part G in them, in which the construction was not in all respects like this lamp.

X Q. 1264. In what respects did it differ?

A. At this length of time I cannot tell in what minute respects differences occurred in our lamps. In one lamp that I recollect, in which the part G was included, the leading-in conductors, instead of being separate spirals, were concentric spirals. In another, I remember straight leading-in conductors were used; in another, I remember conductors of flat metal, folded upon themselves. In another, I remember a spring used as a substitute for the 1375 weight of the part F. In a great many lamps I remember the omission entirely of G; some with springs substituted for the weight of F, and some in which the weight F was used. I remember a number in which neither springs nor weights were used as a substitute for weight F, in which the leading-in conductor with which F connects was made sufficiently flexible to allow the insertion of the incandescent carbon. So that it was held, you may say, by the spring of the whole leading-in conductor.

X Q. 1265. In the lamp of this patent, several differences and additions appear to have been made from the apparatus or lamps of Exhibits 1 and 3. The conductor is straight and perpendicular to the base of the lamp instead of being supported between two parallel leads. The leads are made spiral so as to give greater length. A soapstone disk to prevent downward radiation of the heat is introduced in the centre of the lamp and the base consists of several parts fitted elaborately together. Why were these modifications made?

A. They grew up through a long series of modifications from Exhibit 1, as you call it, for different purposes, and I doubt whether I can now recollect or recall all these changes, or the reasons for them moving us to make them. In fact, I know I cannot remember all. If you desire I will go on to state some of them; I have already mentioned how the diaphragm arose. I have also mentioned the substitution of carbon for metal in the connections with the incandescent conductor. I have also mentioned the clamping of the carbons of incandescent conductors in straight carbon holders, some straight and some arched, so as to rise above the ends of the holders. The arrangement in this lamp is evidently intended to allow for expansion and contraction of the incandescent conductor. The upright position of the incandescent conductor is evidently more favorable to the radiation of light from it in a horizontal direction than a horizontal position of a straight 1376 incandescent conductor, with its holders preventing radiation of light at the ends of such conductors in two directions, casting upright shadows. The diaphragm introduced first for support was supposed to prevent radiation of heat also from the base of the lamp where it was sealed up and where, by expansion and contraction, leaks were most likely to occur. The extended lengths obtained by convolution of the leads was intended to prevent conduction of heat to the glass base where it was sealed in the same. The construction of the base was intended to obtain perfect hermetical sealing of the lamp, so as to preserve its atmosphere uncontaminated.

X Q. 1266. This patent was applied for on the 16th of May, 1878. At this date you and Mr. Sawyer had about completed your experimental work at 43 Centre street, had you not?

A. I do not remember whether we had or not. We did some work there, how much I don't know, according to the best of my recollection, after the application for that patent; the great majority of the work we did was done before this time.

X Q. 1267. When you filed this application I understand you to have considered the lamp described in this patent an incandescent lamp adapted for use?

A. We considered that the lamp there described contained the elements of a practical electric lamp.

X Q. 1268. The lamp of this patent shows a straight carbon fed down upon the block D to compensate for fracture or slight consumption of the carbon. Had you found in your experiments with the apparatus of Exhibit 3, where the carbon was supported between parallel leads, that fracture or consumption of the carbon occurred?

A. In a great many cases the carbons were fractured, and in others some consumption at the ends occurred. In a great many other cases neither fracture nor consumption occurred in the incandescent carbons; the fracture and consumption were considered accidental by us, and it was to compensate, as far as possible, or provide against accident, that this provision in the lamp was made, and also to cover it, this feature, in a patent for a lamp. 1377

X Q. 1269. When you say in your last answer that you consider the fracture and consumption accidental, what do you mean?

A. That it ought not to occur in a well-constructed lamp, properly used and run, but that it was possible that it — occur through faulty construction or charging or accidental use of currents of too great a strengh, as happens to-day in incandescent electric lamps in both respects.

X Q. 1270. Were your lamps well constructed?

A. Yes.

X Q. 1271. Am I to understand then, that if the lamps were properly constructed, charged and run, as yours were, this fracture and consumption would not occur, but that if the lamps were improperly constructed, charged and run, it would occur?

A. I mean that it might occur with all the care that would be ordinarily bestowed in careful manufacture and charging of the lamps and in ordinarily careful use of the same, as it occurs to-day in the incandescent lamps now manufactured, and I mean in this to make a distinct admission that as much was not known then in regard to the manufacture of incandescent lamps as is to-day, nor of the life of a lamp which would render it commercially acceptable. We meant to provide against possible contingencies.

Adjourned till Tuesday, the 18th inst., at 10 a. m.

1378 NEW YORK, *Oct.* 18*th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN continued as follows:

X Q. 1272. I do not quite understand from your previous answers whether, prior to May 16th, in lamps where the carbon conductor was supported by parallel leads, you had or had not been able to prevent fracture or consumption of the carbon conductor at the point of contact between the conductor and the leads?

A. In some case we had, and in some cases there was fracture, and in some cases consumption.

X Q. 1273. You say that in some cases fracture and consumption did occur and in others not. Had you found any means by which sufficient good contact could be obtained to prevent fracture and consumption?

A. Yes; we did not attribute the fracture to the points of contact; nor did it frequently occur there; nor did we attribute the consumption to the points of contact, but to impurity of the atmosphere of the lamps ordinarily; or, in cases other than that, in using too great current, so as to cause arcs where they would not occur with a proper current. In other cases, fracture occurred by the putting of too great tension, or pressure, upon small carbons.

X Q. 1274. I do not as yet understand you. When you began your experiments, one of the first difficulties you encountered was destruction of your carbons, by consumption or fracture, at the points of contact between the carbons and the holders. In your first patent for a lamp, filed May 16th, in enumerating the reasons why, up to your time, no lamp had as yet been devised which would be practically operative, you say:

1379 "Third. The unequal expansion of the carbon and its holders has resulted in fractures of the former, so that, however perfect the atmosphere in the globe, the lamp has never been permanent."

To obviate this defect, you describe in the patent a rod of carbon resting upon a block of carbon D, so held and arranged that as fracture or consumption occurs at the point of contact between D and A^1, the carbon is fed downward. This arrangement does not appear to be to prevent fracture or consumption, but to prevent the disastrous effects of such fracture and consumption, the patent seeming to state that fracture and consumption, by unequal expansion of the carbon and holders, cannot be prevented. Now, was it true, at the time you filed the application for the patent, that you had been unable to devise a method of rigidly holding the carbon conductors and of so connecting them as to prevent fracture and consumption?

A. You cannot expect me to answer yes or no, and so adopt your answer as my testimony in cases like this. You confound two separate and entirely distinct things and apply the wording of the patent to a matter to which it does not refer and then ask me to adopt your question and answer yes or no. I referred in my previous testimony, to which you refer in your question, to the imperfect electrical connections between the holders and the incandescent carbons the consequent formation of electric arcs, the consumption of the ends of the carbons, and melting away of the metal points of contact. Now, you confound this matter with a breakage expressed to be due, not at all to the difficulty to which I referred, but to the unequal expansions of the incandescent conductors and the leading-in conductors and to compensations for this latter difficulty, of which I have not before spoken at all. Again, you confound the kind of destruction or consumption at the ends of the incandescent conductors by the electric arc, of which I have spoken, with 1380 consumption, wearing away or oxidization of the substance of the conductor itself by reason of an imperfect atmosphere, of which I have not spoken. If you ask me the question without your premise, to which I am expected to assent in my answer, I will answer it.

X Q. 1275. Whatever the cause of fracture or consumption may have been—whether due to an arc resulting from imperfect contact, and thus consuming the carbon or metal, or a break or fracture due to unequal expansion or contraction of the carbon and holders—the result would be, would it not, the destruction of the lamp?

A. Yes, if the fracture occurred or the consumption took place, and if, also, there was no automatic compensation provided in the lamp by which the fracture or consumption could be remedied.

X Q. 1276. Now, in order then to rigidly connect the incandescent conductor to its supports and make this connection practical and durable, you would have to so connect them as to prevent fracture or consumption, whatever the cause might be, would you not?

A. Yes, so far as fracture or consumption are influenced by or depend upon the connections.

X Q. 1277. In patent 205,144 you state: "At the present day it is not new to produce a light by causing the electric current to heat a carbon conductor to incandesence in a vacu-m, or in nitrogen, or in other gas; but no lamp has yet been devised which would be practically operative, and for these reasons." You then enumerated as your reasons the following:

"First. The methods that have been employed for charging the lamp with the artificial atmosphere * * * are imperfect.

"Second. It has been found practically impossible, under the varying degrees of heat and pressure, to maintain perfect joints, and the result is that expansion of the artificial atmosphere by the heat from the luminous conductor expels a portion of the same, and 1381 the contraction of the atmosphere, upon cooling, causes a portion of the external air to penetrate the globe." * * *

The third reason you give, why no lamps has as yet been devised which had been practically operative, is that "the unequal expansion of the carbon and its holders, has resulted in fractures of the former, so that however perfect the atmosphere in the globe, the lamp has never been permanent."

Later on you say: "Our arrangement for avoiding fracture of the carbon will be fully described hereinafter."

The patent then describes a structure wherein the incandescent conductor is not final nor rigidly attached to, but rests and is held by pressure upon a carbon, block D, "with a mechanism by which, in the language of the patent, should fracture or slight consumption of the carbon occur at the first lighting, or any subsequent lighting of the lamp, the necessity of taking down the same, renewing the carbon, and recharging the globe, is obviated inasmuch as the weight of rod F gently forces the carbon through the clamp G until a new contact between E and D is established."

As this patent states, that however perfect the atmosphere in the globe, one of the reasons why a practical operative lamp has never been devised, is that unequal expansion of the carbon and its holders has resulted in fractures of the former and shows and describes no method by which a rigid or firm attachment between the incandescent carbon and its support can be made so as to avoid this fracture or consumption, but on the contrary describes an arrangement by which fracture or consumption is not prevented, but the destructive consequences are compensated for by new contact being made, I desire to know whether, at the time you filed this application, you had found a means of firmly and rigidly uniting the incandescent carbon conductor to its electrodes or supports, so that fracture or consumption would not occur?

1382 A. Up to the present time, so far as I know, no positively permanent incandescent electric lamp has ever yet been made. Among the reasons for this are those given in this patent. In answering this question, then, I must be understood as speaking relatively and use the word "permanent" in a relative sense. Using it in such sense, and meaning it permanent, I answer the question, yes, in at least two forms, one of which was intended to be shown in figure 8 of the patent, employing a straight pencil, and the other of which employed an arch form of incandescent conductors held between clamps and rising above the holders, in each of which the connections were rigid and packed with carbon or united to the holders by a deposit of carbon. It will be observed that in figure 8, by description, the clamp G is omitted.

X Q. 1278. You do not mean in your last answer to say that figure 8 of the patent shows a permanent attachment of the carbon E to the block D, or that the patent describes such a connection?

A. No, I do not know that it does. I referred in that figure merely to the form.

X Q. 1279. Do you mean by your 1277th answer to be understood as saying that at the time of the filing of this application, May 12th, 1878, you had devised a means of attaching the carbon conductor to its supports or holders so that fracture or consumption of the carbon would not occur?

A. Yes, any fracture or consumption due to imperfect connection between the incandescent carbon and its holders, or due to unequal expansion and contraction between the carbon and its holders to a practical extent.

X Q. 1280. If that be so, was not such a construction much simpler than the one shown in patent 205,144?

A. Yes, but it did not serve the same purpose as that described in the patent, and perhaps it was nothing new, except possibly the deposit carbon.

1383 X Q. 1281. Do you mean by your last answer that at the time you filed the application, means were known by which a rigid and firm attachment could be made between the carbon and its holders or supports, so that fracture or consumption would not occur by reason of defects in the joint?

A. Yes; or at least they were so simple that we supposed they must have been used.

X Q. 1282. Was it then true, as stated in the patent, that one of the reasons why no practically operative lamp had been devised, was fracture due to unequal expansion or contraction of the carbon in its holders?

A. Yes.

X Q. 1283. Was this statement in the patent intended as a historical statement of fact, or a statement that no fixed joint could be made in which fracture could not occur?

A. It was a statement simply of our views as to the cause of previous failures and in explanation of what we desired to remedy.

X Q. 1284. What made you think that one of the reasons of previous failures was due to fracture at the joint, if, as you have said in your answer to 1281st question, means were known by which a rigid and firm attachment could be made between the carbon and its supports, so that fracture or consumption could not occur by reason of defects in the joint, or were so simple that you supposed they must have been known?

A. I call your attention to the fact that the patent does not state that the fracture is due to unequal expansion of the carbon and its holders at the joint, but simply states that "the unequal expansion of the carbon and its holders has resulted in fracture of the former," omitting "joints." Answering your question directly, I have already stated in my testimony that we found that electric arcs were formed at the joints by reason of imperfect electrical connec-
1384 tion, resulting in the consumption or wearing away of the carbons at those joints. It was so obvious, I suppose, that we assumed that others had observed the same thing, if we did, but we do not state so in the patent, and I do not remember to have so testified.

X Q. 1285. You do state in the patent, do you not, as one of the reasons why no lamp had yet been devised which would be practically operative, that unequal expansion of the carbon and its holders has resulted in fracture of the former, so that, however perfect the atmosphere in the globe, the lamp has never been permanent?

A. Yes, and we show a means of counteracting the injurious effects of this unequal expansion and contraction.

X Q. 1286. In your 1283d answer you say this statement was a statement of your views as to the cause of previous failures and an explanation of what you desired to remedy. In your 1281st answer you say that at the time you filed the application you thought means were known, or they were so simple you thought they must have been known, by which a rigid and firm attachment could be made between the carbon and its holders, so that fracture or consumption would not occur by reason of defects in the joint. If, then, it was so easy to connect the carbons and holders so that fracture would not occur, why did you think that previous failures had been due to imperfect union?

A. I do not know that I have anywhere testified, and have not intended to do so, that previous failures had been due to imperfect union, and the patent does not so state, but that it is due to unequal expansion between the carbon and its holders, to wit, the carbon expanded more or less than its holders and was broken thereby, and not by imperfect connection.

Adjourned till Monday, the 24th inst., at 1 p. m.

1385 MONDAY, *24th October*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1287. Do I understand from your last answer that you mean to say, not that a fracture occurs at the joint necessarily by reason of the unequal expansion and contraction of the carbon and its holder, but that from this cause a fracture is liable to occur in any part of the carbon unless prevented by some proper means?

A. That is what I mean, especially if the carbon is rigidly held by the holders.

X Q. 1288. In the case of a carbon rigidly held by the holders, there are, as I understand you, two elements of danger to be guarded against: first, consumption of the carbon at the ends by the formation of an arc due to imperfect electrical connection or contact, and, second, fracture of the carbon at any point due to inequality of expansion and contraction of the carbon and its holders?

A. Yes, those dangers exist.

X Q. 1289. Now, this patent 205,144, in describing the device or mechanism for feeding the carbon rod down upon the carbon block, states "thus should fracture or a slight consumption of the carbon occur * * * the necessity of taking down the same, renewing the carbon and recharging the globe is obviated." Had you found, at the time of the application for this patent, that consumption of the carbon at the point of contact with the holders, had occurred in practice?

A. Yes, it did sometimes occur in some of our lamps, not always or usually.

X Q. 1290. Would the feeding mechanism of this lamp be
1386 effective in compensating for the fracture of the carbon pencil
at any point other than at the point of contact between the
pencil and the block D, or immediately above it?

A. Yes, up to the part G, provided the pencil above was long enough to reach from G to the block below it.

X Q. 1291. Where, in actual practice did you find that such fracture usually occurred in such lamps as are shown in this patent?

A. At the block D, or at the part G, but fractures were very rare in this form of lamp.

X Q. 1292. If fracture or consumption occurred the pencil E slid down through the pencil G onto the carbon D, and new contact was made, was it not?

A. Yes.

X Q. 1293. Now the current came through the support G, did it not?

A. Mostly, but not entirely.

X Q. 1294. Now G was of metal, was it not?

A. No, I think it was of carbon usually, but I don't remember.

X Q. 1295. The pencil E, being adapted to slip through the support G, did you find in practice that an arc was likely to occur at this point?

A. It sometimes did occur at this point, but was not very likely to occur there, inasmuch as the pencil throughout its whole length was a conductor, and above G carried a portion of the current which caused the illumination of the pencil below G, through which the whole current passed.

X Q. 1296. Now, the pencil E rested upon the block D, being held in position by pressure. Did an arc usually occur at this point of contact?

A. No, it did not usually occur at any point, but in lamps in
which the carbon was not rigidly attached to D, it did sometimes
occur at that point, but rarely.

1387 X Q. 1297. Did D or G, or the part of the pencil which
was inserted in G, or passed above it, become incandescent
when the lamp was lighted?

A. No, it was not intended to do so, but in some of our lamps, before we got them adjusted, it sometimes happened that the upper part of the pencil above G was heated up to a dull red. This showed that the electrical contact at G was not sufficiently good, and the lamps were taken down and adjusted so that they would not heat above the piece G. I am confining my answers to lamps in which the part G was introduced, and have not referred to the other forms shown in the patent in which the part G was not used.

X Q. 1298. Now, a lamp which did not require this feeding mechanism, and in which the carbon conductor could be rigidly held without fracture or consumption form the causes mentioned, would be much simpler in construction and more economical to make than the lamp shown in this patent, would it not?

A. Yes, than the lamp shown in Fig. 1 of that patent, and such a lamp is shown in Fig. 8 of the patent, and we made other forms much more simple of this kind that you speak of.

X Q. 1299. Prior to filing the application for the patent?

A. Yes.

X Q. 1300. When you filed the application for this patent, had you made, or did you think there could be made, practically operative lamps employing a straight stick of carbon in which no feeding mechanism was required and where the carbon conductor was rigidly attached to its holders, and in which fracture of the carbon or consumption at the points of contact did not occur at so early a time as to make the lamp inoperative?

A. Yes, we had made such lamps, a good many of them, and of course I thought and knew they could be made.

1388 X Q. 1301. Why then did you in your first patent describe a lamp in which this more expensive and inferior mechanism was employed?

A. Because we thought that if we did not cover the device of a feeder lamp by our patent others would do so, and we thought it desirable to patent the feeding feature of a lamp.

X Q. 1302. If at the time you filed this application you had, as you say, made lamps simpler and cheaper in construction, and equally efficient, and not having the defects which this feeding mechanism was designed to compensate for, why did you not patent them, or the inventions of such lamps?

A. We did, in this very patent, or intended to do so, so far as the straight pencils are concerned.

X Q. 1303. Please point out where in this patent you have described lamps not employing the feeding mechanism and not having the defects which the feeding mechanism was designed to compensate for.

A. Fig. 8 in the patent is an illustration of such lamp, and Fig. 8 is described in the patent.

X Q. 1304. Please read from the patent what you assert to be a description of a lamp not employing a feeding mechanism, and not having the defects which a feeding mechanism was designed to compensate for.

A. "In Fig. 8 we have indicated a modification of the single-carbon lamp, the clamp G being dispensed with and the bent rod F being provided like the rod I of Fig. 1 with a carbon piece X wired to it precisely as carbon D is wired to rod I," and the whole of the carbon E is rendered incandescent, no part of it being reserved for feeding down upon the block D.

X Q. 1305. And is what you have just read what you assert to be a description of lamps not employing the feeding mechanism and not having the defects which the feeding mechanism was designed to compensate for?

1389 A. Yes, taken in connection with the rest of the patent, it is an illustration and description of a lamp of that character, and is one form of lamps of that character which we made. In this case the part F simply acts as a compensating device for unequal expansion and contraction of the incandescent carbon and its holders.

X Q. 1306. Is there any statement in the patent that the modification in Fig. 8 does not employ the feeding mechanism which you have described in the patent?

A. There is an omission in Fig. 8 of any carbon to be fed and of any holder for a new carbon or part of a carbon to be fed (such as the part G), which amounts to the same thing. It would be unnecessary, it seems to me, to state that anything that was not a feeder lamp was not a feeder lamp; the drawing being part of the description.

X Q. 1307. All that I see in the patent concerning Fig. 8 is the statement that in Fig. 8 you have indicated a modification of the single-carbon lamp, the modification being stated to consist in the omission of the clamp G, and in such case providing the bent rod F with a carbon piece X wired to it as the carbon is wired to rod I. Now, the single-carbon lamp employed the feeding mechanism of the bent rod F sliding in the part H. Now, what is there to indicate that after you have performed the modification shown in Fig. 8 that the rod F does not still slide in the part H?

A. There is nothing, but the total omission of a carbon to be fed shows that it is not and cannot be a feeder lamp; again, the omission of any holder or receptacle for a carbon or part of a carbon to be fed, which is the office of the part G in Fig. 1, also shows that Fig. 8 is not an illustration of a feeder lamp. In Fig. 1 the part F exercises two functions, the first of which is to maintain electrical connection or contact between the carbon and its holders and compensate for unequal expansion and contraction between the incandescent carbon and its holders, the second of which functions
1390 is to feed a new part of the carbon down upon the block D
in case of fracture or consumption. In the illustration, Fig. 8, the rod F only serves in its function of maintaining contact and compensating for unequal expansion and contraction by the movement or sliding to which you refer.

X Q. 1308. You think then that Fig. 8, taken in connection with the description you have quoted, shows a lamp in which no feeding mechanism is employed?

A. Yes, and the absence of any method or attempt to introduce any compensation by which the electrical resistance of the lamp should be maintained the same or substantially the same, a function which the part G exercises in Fig. 1 further confirms me in that opinion.

X Q. 1309. Is there anything in the patent which states or indicates how in Fig. 8 the carbon E was held between the holders?

A. I think the illustrations, figures of the patent, show it. I don't remember whether it is referred to in the text or not.

X Q. 1310. Well, please tell me how you think the patent states that the carbon E in figure 8 is held?

A. Figure 8 shows that it is held between X and D. I don't know that there is anything further than that.

X Q. 1311. Is it rigidly and firmly held?

A. I do not know that there is anything in the patent to show whether it is rigidly held or simply kept in place by insertion into the parts D and A, and by the weight of F and X.

X Q. 1312. Now the feeding mechanism of the lamp was, as we agree, to compensate for fracture of the carbon or consumption at the points of contact between the carbon and its holders. What is there in the patent or in any of the drawings to show that in the modification of Fig 8 fracture or consumption would be avoided.

1391 A. The movability of the part F, and the fact of its weight, the movability of the part F being a compensation for unequal expansion of the incandescent carbon and its holders, and the gravity of F acting to maintain the electrical contact notwithstanding expansion or contraction in the length of the incandescent carbon, differing from the expansion or contraction in the length of its holders.

X Q. 1313. Then the part F, in the modification of Fig. 8, does slide in the part H?

A. It does, as shown in the patent.

X Q. 1314. If in this modification, consumption of the carbon at the points of contact with its holders should occur, F would also slide in the slot H and preserve the contact?

A. Yes, and the arc being established, the resistance of the incandescent carbon would be reduced as its length was diminished, and in all probability the arc re-established by a greater current due to diminished resistance, and this process would be continued and increased and the carbon consumed.

X Q. 1315. Would not that likewise occur in the lamp of Fig. 1?

A. Not to the same extent, the distance between G and D being maintained in the lamp of Fig. 1, the resistance of the lamp would remain more nearly constant and the arc would not be likely to be renewed, as the current mainly and almost entirely passes through G.

X Q. 1316. If, as you now say, the modification of Fig. 8 preserved the sliding of F in H, so that if there was consumption at the points of contact the carbon would be fed down, as would also occur if a fracture occurred in the carbon at or near the block D, how can it be true as stated in your 1302d answer that this patent, patented a lamp in which no feeding mechanism was employed and which did not contain the defects which feeding mechanism was designed to compensate for?

1392 A. I say so, because we made such lamps; they were practical lamps without any feeding, and they were not feeder lamps, in any practical sense. If the carbons broke, or if an arc occurred it was a practical end to the life of the lamp of that kind.

X Q. 1317. If, as stated in your 1300th answer, at the time the application for this patent was filed you made and thought there could be made practically operative lamps employing a straight stick of carbon in which no feeding mechanism was required, and where the carbon conductor was rigidly attached to its holders, and in which fracture of the carbon or consumption at the points of contact did not occur at so early a time as to make the lamp inoperative, and inasmuch as the modification of Fig. 8 still employs the sliding of F in H, what explanation, other than as given in your 1301st answer, have you to give for the description in this patent of this expensive and unnecessary construction?

A. I do not think any further explanation is required; I remark that if one's foresight were as good as his hindsight, you would not now be asking me this question: but again, if further explanation is required, it will be found in the fact that this art was then new and substantially unpracticed, nevertheless, incandescent lamps and semi-incandescent lamps or feeder lamps had been made, or tried to be made, before that time. We did not know which would prevail; the present state of the art has after years and years, as it appears at present, answered that question; we did a great many unnecessary things without doubt, which under the light of the present day we would not have done.

X Q. 1318. Why did you not at this time describe or patent the lamp employing a straight stick of carbon held rigidly between its supports which did not require this complicated, expensive and useless mechanism?

A. I do not know that we did not do so. I think that some of the elements of this lamp which we patented are in the incandescent lamps of to-day. If we did not patent anything that we
1393 ought to have patented, it was perhaps due to the fact that
my coworker, Mr. Sawyer, was to pay all the expenses of obtaining patents, and desired to avoid all expense that he could in that direction, and alleged that when the company was formed (that was to be formed), patents could be taken out for less and minor things and details; it was largely due to this fact that more patents were not taken out.

Adjourned till Tuesday, 25th inst., at 1 p. m.

TUESDAY, *25th October*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1319. The second patent granted to Sawyer and Man for an electric lamp is patent No. 210,809, the application for which was filed November 5, 1878. Does not the lamp of this patent employ a mechanism to provide against expansion or contraction of the carbon, and by which mechanism, if the carbon were consumed by arcs at the point of contact between the carbon and the holders, contact would still be preserved by the holders approaching each other through the action of a spring?

Objected to as incompetent, irrelevant, immaterial and not proper cross-examination; the patent referred to not being the patent in suit, and having nothing whatever to do with the issues in this controversy.

A. It contains the kind of mechanism which you mention, but not for all the purposes which you mention, nor would it practically so act; the object of the device referred to in the lamp was to provide for expansion and contraction, and make and keep good 1394 electrical connection between the incandescent carbon and its holders. It was not a feeling device; it would not practically so act, because when the electrical connections between the incandescent carbon and its holders were not sufficiently good to prevent an arc being formed between the carbon and its holders, the practical life of the lamp was ended.

X Q. 1320. In the lamp of this patent, was not the incandescent carbon held in position by the pressure of the spring W acting upon the stirrup V, and was not the operation of the mechanism as follows: Upon any expansion of the carbon additional pressure being exerted against L, the spring yielded before fracture of the carbon occurred; if the carbon contracted, contact was preserved by the spring pressing upon the holder L?

Same objection.

A. Your description of the working of the apparatus is substantially correct, but it does not wholly explain the working of this part of the apparatus. The ends of the incandescent carbon were in practice by us rigidly attached to the holders in most cases: where not so done, in the working of the lamp, they became so, soon after it was heated up. Now, if the holders were rigid and kept at a fixed distance from each other when the carbon was heated up it would be expanded in length, and if by compression at high heat it endured the strain of such expansion, when it was cooled off it would be shorter than the distance between the holders and would be pulled apart by contraction either at some point in its length or at its ends, breaking the electrical connection.

X Q. 1320½. Is there anything in this patent showing or stating that the incandescent carbon was rigidly attached to its holders?

Same objection.

A. No, but such was the fact of practice and such became the fact by use.

1395 X Q. 1321. Now, if an arc in such a lamp as is shown in this patent should form at the points of contact between the carbon and its holders and the carbon at this point begin to consume, would not the spring operate to bring the holders nearer together until the carbon was consumed?

Same objection.

A. Yes, until the carbon was consumed or fell out of the holders, which would soon take place; the practical life of the lamp would ordinarily be ended when the arc was formed.

X Q. 1322. Now, did not the strength of this spring have to be adjusted with reference to the size and strength of the carbon conductor?

Same objection.

A. It did.

X Q. 1323. In the lamp of patent 205,144 the sliding mechanism had to be adjusted with reference to the strength and size of the carbon conductor?

Same objection.

A. Yes.

X Q. 1324. Did you consider at the time you filed the application for patent 210,809 that the spring mechanism of this lamp was superior to the sliding mechanism of the lamp of patent 205,144 as avoiding fracture from expansion or contraction?

Same objection.

A. I cannot recollect, but I suppose that we did; I am confident of it so far as the lamp shown in Fig. 1 of patent No. 205,144 is concerned, and I believe we did so far as the device shown in Fig. 8 of that patent is concerned.

X Q. 1325. Now, if at the time you filed the application for the patent 205,144, some six months before this patent 210,809 was filed, as stated in your 1300th answer, you had made practically operative
lamps employing a straight stick of carbon in which no feed-
1396 ing mechanism was required, and where the carbon con-
ductor was rigidly attached to its holders and in which fracture of the carbon or consumption at the points of contact did not occur at so early a time as to make the lamp inoperative, what was your reason for describing and claiming in this patent this spring mechanism for preventing fracture of the carbon?

Same objection.

A. I have already explained the difference between a feeding device and a compensation for expansion and contraction, and although some parts of the one may be employed in the other, they are not employed as feeding devices, nor have I intended to state that no compensation was introduced into our lamps for expansion and contraction.

X Q. 1326. I do not wish any misunderstanding to occur. Now, in patent 205,144 is shown and described a sliding mechanism, which, as the carbon lengthens or shortens, either yields or follows the shortening; in patent 210,809 is shown a spring mechanism which gives as the carbon lengthens or follows it as it shortens; whatever other functions these devices may perform I understand we agree that they are intended to prevent or avoid fracture of the carbon due to its expansion or contraction. Now, please tell me whether prior to the filing of the application for the patent 205,144, on May 16th, 1878, you had made lamps and thought there could be made, lamps practically operative employing a straight stick of carbon in which no mechanism was required of the kind shown in either of these patents for providing against fracture of the carbon by its expansion or contraction, and where the carbon conductor was rigidly attached to its holders, and in which lamps fracture of the carbon or consumption at the point of contact, did not occur at so early a time as to make the lamps inoperative?

Same objection.

1397 A. In nearly all of our lamps, substantially all, some expedient was used to compensate for and prevent the injurious effects of expansion and contraction of the incandescent carbons, sometimes one device and sometimes another. The sliding device shown in patent 205,144, as applied to lamps of the form shown in Fig. 8 of that patent, relying simply upon gravity for that purpose, were deemed, at the time that patent was taken out, equivalent for all other forms, such as springs; we had made a few lamps at that time, and only a few, in which all the conditions existed which you state in your question; the carbons usually broke in these lamps at the second or third time they were lighted up; after that, some compensation was always introduced by us for contraction and expansion; I have reference now only to straight pencils, to which I understand your question to refer.

X Q. 1327. You say in your answer, that nearly all of your lamps employing a straight stick of carbon had some sliding or spring mechanism to compensate for expansion or contraction, and thus avoid fracture. You also say that you had made a few lamps having the conditions mentioned in my question, but that in these lamps the carbon usually broke at the second or third lighting. I do not understand from your answer whether at the time you filed your application for patent 205,144, you had made lamps which you considered practically operative, employing a straight stick of carbon rigidly held to its supports, and in which no spring or sliding mechanism was required to compensate for expansion or contraction of the carbon, and in which fracture did not so early occur as to render the lamp practically inoperative; please tell me whether you had or had not at that time made such lamps?

Same objection.

A. I have stated the facts in regard to the matter and I do not
desire in any way to seem by my answers to avoid explicitly
1398 answering your question; the few lamps to which I refer
were practically operative during their first lighting up,
some of them during their second and probably their third lighting up; beyond that the carbons broke, and they were not further practical lamps; they were practical lamps to the extent only that I have stated; they were not enduring lamps beyond that extent.

X Q. 1328. Did the fracture occur at so early a period in the life of the lamps as to render them, in your judgment, inoperative as lamps?

Same objection.

A. No; they were operative to a limited extent, such as I have stated.

X Q. 1329. I cannot yet understand from your answers whether you had made lamps of the kind mentioned in my question 1326 which you considered practically operative as lamps?

Same objection.

A. Yes, practically operative, so long as the carbons were not broken, but not enduringly operative.

X Q. 1330. What I want to know is whether the carbon broke at so early a stage in the life of the lamp as to make the lamp practically inoperative as an incandescent lamp?

Same objection.

A. Yes, for those purposes and uses where a lamp was required to be used with the same carbon and in the same atmosphere, beyond its first, second or third lighting up. No, for those lamps whose requirement in use was only to be lighted up once, or at most twice or thrice, without putting in a new carbon and recharging the lamp.

X Q. 1331. Now, a lamp which was so made that the straight carbon pencil did not break and have to be renewed was superior to a lamp the same in other respects in which the pencil would break and have to be renewed?

Same objection.

1399 A. Yes.

X Q. 1332. If such a lamp as is shown in patent 205,144, the carbon pencil would not break by reason of its expansion or contraction, and if an arc did not occur to consume it, the feeding or compensating mechanism would be entirely unnecessary and useless, would it not?

Same objection.

A. Yes; but it would fracture were it not for the compensating mechanism.

X Q. 1333. Did you then, at the time you filed the application for patent 205,144, believe, and had your experience taught you, that a straight pencil of carbon used as an incandescent conductor would fracture by reason of its expansion or contraction, and that a compensating mechanism was necessary?

Same objection.

A. Our experience was that straight carbons held rigidly without compensation for expansion and contraction—that is, some device allowing them to expand or contract in their length—would be broken soon after, but not at their first lighting up, and we thought some compensating device allowing for such expansion and contraction highly desirable.

X Q. 1334. Sufficiently desirable to justify the additional cost of the compensating mechanism?

Same objection.

A. We thought it might be, and, I believe, we thought it was.

X Q. 1335. You began your experiments, you have said, by holding the carbon between two parallel holders. Did you ever devise a compensating mechanism for a straight piece of carbon so held?

Same objection.

A. Yes.

X Q. 1336. When you filed the application for patent 205,144,
did you consider the apparatus there shown as the simplest
1400 and most efficient compensating mechanism you had then
made where a straight stick of carbon was employed?

Same objection.

A. No.

X Q. 1337. Why did you describe in the patent this, when you had a simpler and more efficient one?

Same objection.

A. Because Mr. Sawyer thought that the device shown in that patent was the equivalent of the other devices which we used, and we desired, or rather he did, to patent the feeder-lamp feature of that patent, which showed at the same time the compensation for expansion and contraction.

X Q. 1338. When you applied for patent 210,809 the spring mechanism there described the simplest and most efficient you had obtained for compensating for expansion and contraction where a straight stick of carbon was employed. This lamp, I understand you to have said, did not have the feeder principle?

Same objection.

A. At the time when the directions were given to the solicitor to apply for that patent, we deemed the compensating device shown in it the best, all things considered, and taken in connection with the other parts of the lamp for the purpose for which it was intended, not perhaps in all its details, but in its main features.

X Q. 1339. Did you at that time consider where a straight stick of carbon was employed a device compensating for the expansion and contraction of the carbon desirable?

Same objection.

A. Yes, I think that we did.

X Q. 1340. Sufficiently so to justify the expense of the compensating mechanism?

Same objection.

A. I think that we did.

Adjourned till Wednesday, the 26th inst., at 1 p. m.

1401 WEDNESDAY, *Oct.* 26, 1887.

Met pursuant to adjournment.

Present, counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1341. In view of the fact that a carbon conduc- of such a lamp as is shown in patent 205,144, had to support the weight of the sliding mechanism, and that the carbon conductor of lamp

210,809 had to resist the pressure of the springs, could a delicate, small carbon be used in lamps of the kind shown in these patents?

Same objection.

A. Not carbons of the smallest size in the first form 205,144. In 210,809, very thin and tenuous carbons could be used.

X Q. 1342. What was the weight of the sliding mechanism in 205,144?

Same objection.

A. I cannot state. We made them of various sizes and weights. The weight of all was slight, unless in lamps where large carbons — used.

X Q. 1343. What was the pressure upon the carbon rods exerted by this sliding mechanism?

Same objection.

A. Substantially the same as the weight of the sliding part F.

X Q. 1344. What was the lightest one you ever made or used in a lamp about?

Same objection.

A. I don't know, and I never weighed one. I can only express it by saying it was of very small weight.

X Q. 1345. Lighter than an ounce?

Same objection.

A. A very small fraction of an ounce, I should think.

X Q. 1346. As light as the tenth of an ounce?

1402 Same objection.

A. I don't know. I should think much less.

X Q. 1347. Less than the twentieth of an ounce, should you think?

Same objection.

A. I don't know.

X Q. 1348. Was it made of metal?

Same objection.

A. No, ordinarily we made them of carbon. Some were made of metal.

X Q. 1349. Now, where the carbon expanded the part F slid upward, pressed by the carbon, did it not?

Same objection.

A. Yes.

X Q. 1350. And when it contracted it slid down upon the carbon?

Same objection.

A. It slid down with the carbon, keeping in contact with it.

X Q. 1351. In view of these facts and in view of the fact that the pressure was not in the same line as the line of movement between the parts, but was exerted on a cross-piece at right angles to the line of movement, which would require a greater force to cause the parts to slide than if it were in the same line, can you not tell me what was the smallest carbon in length or cross-section which you used in an operative mechanism of this character?

Same objection.

A. Not from the data you give, but I can give my recollection in regard to the carbons that we did use. They were somewhat less than a twentieth of an inch in diameter ordinarily, and some of less diameter and of an ordinary length of about five-eighths of an inch in the incandescent portion, and some of slightly greater length.

X Q. 1352. What was the smallest carbon in cross-section 1403 you ever used in a mechanism of this character which would cause the parts to slide as it expanded or contracted?

Same objection.

A. The smallest carbons, to the best of my recollection, used in such a mechanism, were from a thirty-second to a fortieth of an inch in diameter. It would not be right to say that these carbons by their expansion or contraction moved the sliding parts upon each other, the sliding motion being due more to the expansion and contraction of the sliding parts themselves and that due to the expansion and contraction of the incandescent carbon was almost infinitesimal in amount.

X Q. 1353. Did not the carbon have to stand the strain necessary to cause movement of the parts, whether that movement was caused by the expansion and contraction of the holders or of the carbon?

Same objection.

A. Yes, in the one case as the fulcrum for the movement, in other case as causing the movement.

X Q. 1354. You have given the diameter of carbons that would stand this strain and operate this mechanism as from the thirty-second to the fortieth of an inch. Now of carbons of this small size what was the greatest length of the incandescent part of the carbon that would so operate and work this mechanism?

Same objection.

A. About half an inch, according to the best of my recollection. Some were perhaps longer, but I cannot be certain of it.

X Q. 1355. The thinner the carbon, the shorter it had to be to work this mechanism; as you increased the length of the carbon, you would have to proportionately increase its diameter?

Same objection.

A. Yes.

1404 X Q. 1356. In such a lamp as is shown in patent 210,809, what was the pressure of the spring there shown upon the holders?

Same objection.

A. Very slightly in excess of the weight of the lower block, which held the lower end of the carbon; as nearly the weight of that block as we could make it.

X Q. 1357. Now, what was the smallest carbon in cross-section and greatest in length, that you ever used in a lamp of this character, in which the spring mechanism operated as designed?

Same objection.

A. I cannot at this length of time remember exact dimensions. The best of my recollection is, that we used carbons in this form of lamp as small as a sixty-fourth of an inch in diameter, but they may have been larger; but less than those we used in the other form of lamp. In length the longest, I should think, that we used, was two inches. Whether this length was of the smallest size of carbons or not I cannot recollect. They were less in diameter than the ordinary carbons that we used, and I think the nearest approximation would be a thirty-second of an inch in diameter. I think we used carbons of this small diameter of two inches in length, but at this length of time I would be unwilling to swear that they were so long; our ordinary carbons of the smallest size that we used were from half to three-quarters of an inch long. I am referring in my testimony to straight pencils.

X Q. 1358. Did you think at the time the application for the patents No. 205,144 and 210,809 were respectively filed that they described operative mechanisms and practical lamps?

Same objection.

A. Yes, I knew they did.

1405 X Q. 1359. Now, on the 31st of March, 1880, you individually applied for a patent upon a lamp, upon which subsequently letters patent No. 227,118 were issued, a copy of which patent I hand you. In that patent you say, "Tension, torsion or compression upon the pencil acts in the end by continual repetition to destroy it." At the time you filed the application for this patent, were you still of opinion that a practical lamp could be made, in which tension, torsion or compression was exerted upon the incandescent carbon?

Same objection.

A. I do not recollect any impression in regard to it at the time. I think the statement in that patent is correct, that in the end tension, torsion or compression operate to destroy the carbon, if other causes do not destroy it before it is destroyed by those things. I knew before then that tension, torsion and compression had been so compensated for by us, that is, Sawyer and Man, that operative practical electrical lamps had been made and used by us.

Defendants' counsel offer in evidence U. S. letters patent to Albon Man for electric lamp, dated May 4th, 1880, No. 227,118 and the same is marked "Defendant's Exhibit Man Patent No. 227,118, October 26th, 1887."

Exhibit objected to as incompetent, irrelevant and immaterial, having nothing to do with patent in suit and having no reference to anything mentioned in the bill or answer, and notice of motion is given to strike it out.

X Q. 1360. Now, on such lamps as were shown in patents 205,144 and 210,809, tension, torsion or compression was exerted on the carbon pencil, was it not?

Same objection.

A. Compression was exerted in the lamp of the first patent to a very slight extent, but not tension or torsion. In the lamp of the second patent it might happen that tension or compression might take place to a very slight extent, and to this extent only, if the lamp was not in all respects properly adjusted. 1406 If properly adjusted, tension and compression were substantially eliminated, certainly sufficiently so to avoid any practically injurious effects therefrom. In neither form of the lamps was torsion exerted.

X Q. 1361. It would seem from this patent, that at the time you filed the application for the patent you regarded as a defect any tension, torsion or compression upon the incandescent conductor; was that your opinion?

Same objection.

A. Not as stated. My opinion is better expressed by saying that such tension, torsion or compression as would end the life of the lamp before it would otherwise naturally be ended, was to be avoided, if possible.

X Q. 1362. Well, you thought then, that these were defects, and that the extent of the defect was commensurate with the extent of the tension, torsion or compression; am I right?

Same objection.

A. I don't remember to have thought in that way. I did think, in all probability, that it was desirable to avoid tension, torsion or compression, especially excessive tension, torsion or compression.

X Q. 1363. If then, when you filed the application for patent 227,118 on March 31st, 1880, you regarded any tension, torsion or compression on the incandescent conductor as a defect, were not the lamps of patents 205,144 and 210,809 defective in so far as they by their structures exerted compression on the conductor, and if lamps could have been made in which the straight carbon pencil never had any such compression upon it, would it not have been desirable?

Same objection.

A. First, I did not, then, to the best of my judgment, regard or believe that suitable tension or compression, such as the carbons would endure throughout their life without being destroyed as injurious, because it had no practical effect upon the life of the 1407 lamp; excessive or unsuitable compression or extension, such as would interfere with the life of the lamp before it would be destroyed by other causes, I must have regarded as injurious. The lamp of the patent 205,144, I think, had not as good compensation as the lamp of the patent 210,809. Perhaps the lamp of the first patent might be considered defective in this particular, although we made many lamps of that kind that were good. The lamp of the patent 210,809 was not defective in my judgment by reason of any excessive pressure upon the carbons, and my patent 227,118 was taken out simply as another way, I thought, possibly, better and cheaper, to avoid pressure than the lamp 210,809. It is manifest that by removal of all pressure, tension and torsion, the danger of excessive pressure, tension and torsion is removed. It would, therefore, in that sense, be desirable to make lamps in which no tension, torsion or compression existed upon the straight pencil of the carbon. I am speaking here simply of tension, torsion and pressure in their effect upon the carbon, and not with reference to the use of pressure for any purpose in the lamp.

X Q. 1364. Now, let us see. Upon the carbon of patent 205,144 there was a pressure equal to the weight of the entire upper holder. On March 31st, 1880, you applied for a patent in which you say, among other things, compression upon the pencil acts in the end to destroy it. Now, when you filed this application on March 31st, had you any opinion as to whether the pressure on the carbon in a lamp like patent 205,144 was a defect which would destroy the pencil?

Same objection.

A. No, I don't remember to have had.

X Q. 1365. Then this defect of pressure on the pencil, which in this late application you say would destroy it was an imaginary conclusion of yours, and not the result of experience; or, in other words, you were speaking of a defect which you had not found to exist?

1408 Same objection.

A. No, that is not so. We had found that excessive pressure was injurious, and I was not speaking of any imaginary thing.

X Q. 1366. But you say excessive pressure did not exist in such a lamp as 205,144, and that a lamp like 210,809 was still better. Now, at the time you applied for this patent on March 31st, 1880, there had issued to Sawyer and Man two patents showing electric lamps. In each of these patents the lamps respectively shown are so constructed that there is pressure upon the straight carbon pencil, and it is by this pressure, or the removal of it, that the conductor is allowed to expand and contract, so as to avoid fracture. This patent of yours states that compression on the pencil will in the end destroy it. Now, I would like to know, whether at the time you filed this application, you considered the pressure necessarily exerted on the pencil in such a lamp as 205,144 a defect, and whether, if you so thought, your opinion was based on experience with such lamps? If you did so think, please tell me?

Same objection.

A. I do not remember to have thought anything about either of those lamps at the time of my applying for the patent 227,118, and don't think I did, and my patent was not applied for to remove or remedy any defect in either of those lamps peculiar to them or because it existed in them. It was applied for by me because it was my own invention, belonged to me, and I thought it was a simple way of avoiding tension, torsion or compression upon a straight pencil—things which I had before then discovered might be injurious if excessive. The patent has always remained mine, and is mine to-day. I have never assigned it.

Adjourned till Thursday, the 27th inst., at 1 p. m.

1409 THURSDAY, *Oct. 27th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN proceeded as follows:

X Q. 1367. Then, as I understand you, you have never thought that if the lamps of these patents were properly made, the compression or pressure on the conductors was sufficient to be a defect of the lamp?

Same objection.

A. No, not with carbons adapted to the lamps.

X Q. 1368. I understand the smallest carbons were not adapted to these lamps, or rather, these lamps to such carbons?

Same objection.

A. No; not well adapted to the smallest carbons.

X Q. 1369. Am I correct in understanding that, according to patent 205,144, the lamp of such patent had an atmosphere of nitrogen at ordinary atmospheric pressure?

Same objection.

A. The pressure of the gas in the lamp, as described in that patent, at the time of its sealing up was the same as that of the atmosphere, but as soon as it cooled off it was at less pressure than the atmosphere was, because in its passage through the heated tube for purifying it its temperature was raised and the gas in the lamp at the time of sealing up was hot, and at a higher temperature than after it had cooled off.

X Q. 1370. Was the heated gas passed through the lamp sufficiently long before sealing to heat the lamp to near the temperature of the gas?

Same objection.

A. Yes, the lamp itself became warm.

1410 X Q. 1371. As I read this patent, you state, that in a lamp containing an artificial atmosphere at atmospheric pressure, when the conductor was run to incandescence, the heat generated would cause expansion of the atmosphere tending to force it out of the lamp, and upon the current being turned off and the atmosphere cooling, air from the outside would rush in and therefore a tight seal would have to be made?

Same objection.

A. The statement contained in the patent, is a statement of what we understood the facts to be before our work. The inference which you draw from this statement is perhaps correct. The lamp should be tightly sealed.

X Q. 1372. Had you found that when the lamp was not tightly sealed the atmosphere would be forced out when the lamp was run to incandescence, and atmospheric air come in when the current was turned off?

Same objection.

A. I do not recollect any such finding. It is manifest that such would be the case if the atmosphere of the lamp were at atmospheric pressure and the same temperature as the air, before it was heated up by the current or incandescent carbon.

X Q. 1373. You say in this patent, "As a safeguard against an infinitesimal leakage we prefer to place in our lamps a small quantity of sodium, potassium or other agent having a great affinity for oxygen," and claim doing so in the 17th claim of the patent. At the time you filed the application for this patent, did you prefer placing in your lamps a small piece of sodium, potassium or other agent having a great affinity for oxygen?

Same objection.

A. Yes, I think so.

X Q. 1374. Was the object of this sodium or potassium to absorb any oxygen that remained or got into the lamp?

Same objection.

1411 A. It was.

X Q. 1375. Had you found that oxygen got into the lamps after their sealing?

Same objection.

A. Yes, I think we had in our earlier lamps, before the lamp of this patent, or rather before the method of sealing up the lamp described in this patent was adopted by us.

X Q. 1376. In lamps such as are shown in this patent, had you found, up to the time of filing the application, that oxygen got into the lamp chamber?

Same objection.

A. No, I do not remember that we did, other than oxygen or air set free in the lamp chamber after it was charged from the walls of the lamp and its interior work, and I do not remember any trouble from oxygen, so set free in lamps of the character of those in this patent; I think we had got rid of that difficulty before these lamps were made.

X Q. 1377. Then at the time you filed this application did you know that in a lamp, such as is described in this patent, and properly made, there was no necessity or use in placing sodium or potassium in the lamp?

Same objection.

A. No, I do not think we knew that there was no use in doing it. We introduced it as the patent says, as a safeguard in case the lamps were not properly sealed and the workmanship absolutely perfect, or nearly so, against, as we say, "infinitesimal leakage." I believe that we at times thought that it would not be necessary to put sodium or potassium in lamps well and perfectly made and sealed, but as absolute perfection of workmanship and manipulation could not be obtained, it was well to put it there, and we thought that its use might be valuable as an independent thing in lamps of any kind made by ourselves, or others, in which the construction was not so nearly perfect as to avoid infinitesimal 1412 leakage; we, therefore patented it as a precautionary expedient.

X Q. 1378. But you know that in a lamp made according to the description of this patent, where the best and most skillful workmanship was employed, this was entirely unnecessary?

Same objection.

A. I do not think, and I have said that I did not think, that at the time we knew "it was entirely unnecessary," but we believe it to be so; we believed that it was not necessary in such perfectly constructed lamps.

X Q. 1379. The patent also says "as an additional safeguard we prefer to place in our lamps a quantity of freshly burned lime" as an absorbent of carbonic acid gas, and in the 16th claim of the patent this idea is claimed; why was this lime put in the lamps?

Same objection.

A. By reason of its higher affinity for carbonic acid gas than sodium or potassium has.

X Q. 1380. What was the desirability of an absorbent of carbonic acid gas in the lamps?

Same objection.

A. To purify the atmosphere of the lamp from that gas and keep it pure.

X Q. 1381. Where did the carbonic acid gas come from?

Same objection.

A. It might come from two or three sources; it might be with the atmosphere with which the lamp was charged, or the interior walls and works of the lamp, and be gradually freed in the latter case by diffusion, or it might come from union of the oxygen of any infinitesimal portion of air that should get into the lamp, or be left in it, combining with the carbon of the incandescent conductor when highly heated up.

1413 X Q. 1382. At the time you filed this application what had been your experience; did these things, or any of them, occur which you mention, and have you found that carbonic acid gas was present in the lamp chamber?

Same objection.

A. Yes; prior to the filing of the application we had found carbonic acid gas in the chambers of our lamps and traced its source, as we thought, as I have stated in my last answer.

X Q. 1383. Did you, then, when you filed this application, consider it important to place lime in the lamp chamber?

Same objection.

A. I do not know that I could state it so strongly as that; we considered it sufficiently desirable as an expedient and precaution to patent it.

X Q. 1384. If, in practice, no carbonic acid gas was present in the lamp chamber this lime would perform no useful function; what I would like to know is whether, when you filed the application you believed carbonic acid gas would be developed in the chamber and, therefore, thought it would be useful; or whether you believed no such carbonic acid gas would be present and therefore thought it useless. Which was the case?

Same objection.

A. Neither; we knew that in all probability oxygen in some proportion would be in these lamps, as it is in those of to-day; that that oxygen would sooner or later unite with the carbon of the incandescent conductor and form carbonic oxide or carbonic acid gas, for which freshly burned quicklime would have a very high affinity and would take it out; now, the practicability of a lamp would depend upon the amount of this oxygen; lamps with an atmosphere containing so high a percentage of oxygen, or subsequently receiving it, as to be impracticable by reason of their short life might be rendered more practicable by the absorption of that oxygen and by the absorption of
1414 the carbonic acid formed from it, if the atmosphere of the
lamps was sufficiently good, no lime was needed; we, therefore, as I said, patented it as an expedient or precaution.

X Q. 1385. I am not asking about hypothetical lamps but lamps made in accordance with this patent. Now, when you filed this application did you think it was necessary to put lime in the lamps, or did you not think it was necessary, or had you no opinion whatever on the subject?

Same objection.

A. I have not talked of hypothetical lamps. I have spoken of the atmosphere of this lamp and all other lamps. I do not think that in a properly constructed lamp, made upon the plan of this patent, we, at the time, deemed it necessary to use quicklime in them; I believe that we thought and knew that in some lamps freshly burned quicklime was useful. The fact is, that we found quicklime useful in some lamps that we made before this form of lamp; we did not, to the best of my recollection and belief, find it necessary in this lamp when properly constructed and charged.

X Q. 1386. It is stated in the specification of this patent, 205,144:

"It has been found practically impossible, under the varying degrees of heat and pressure, to maintain perfect joints, and the result is that expansion of the artificial atmosphere by the heat from the luminous conductor expels a portion of the same, and construction of the atmosphere upon cooling off causes a portion of the external air to penetrate the globe, thus supplying oxygen, which at the next lighting feeds upon the carbon."

Later on the specification says:

"To guard against great heating and unequal expansion at the joints, which would imperil the lamp and soon render it useless, we isolate the incandescent carbon from the lower part of the 1415 globe where the joints are situated by a disk or diaphragm of some refractory substance, preferably soapstone or porcelain, whereby we prevent all downward radiation of the heat and keep the joints comparatively cool at the same time that the upper part of the globe may be very hot.

"Furthermore to prevent conduction of the heat from the incandescent carbon to the joints by the metallic connections communicating therewith, we arrange the two conductors leading upward from the base in a spiral volute, or fluting form, so that we obtain considerable length of conductor in a limited space and very little of the heat reaches the base."

Now, when you filed this application did you consider this soapstone disk necessary on such lamps as are shown in this patent?

Same objection and the further objection that it does not appear by the question what lamps are referred to as containing the defects mentioned in the first part of the matter quoted from the specification, whether of the lamp of the patent or lamps that had gone before.

A. The lamps constructed as those shown in this patent are, were run by us to an extremely high incandescence, much higher and giving much more light than the ordinary incandescent lamps of to-day—several times the candle power now ordinarily employed; we used the large currents and this high incandescence because at the time we considered it highly desirable in our incandescent electric lamp. In such lamps run to the high incandescence I have spoken of, much greater heat was developed than in the lamps of to-day. I believe that at the time we thought this high incandescence and great light necessary to the introduction of incandescent electric lighting. To provide against the effect of this large heat the devices of which you have spoken, were introduced by us into the lamp. I believe we considered them necessary under the circumstances of use which I have stated.

1416 X Q. 1387. You say you believe you considered them necessary. Was this opinion theoretical, or had you found that where the disk was not employed perfect joint could not be maintained. I am speaking, of course, of lamps of this patent?

Same objection.

A. We found that the use of the disk and of the long conductors, or conductors formed specially to radiate heat, prevented heating of the base of the lamp, and that perfect joints could be maintained by their use. In lamps where they were not used, the bottoms of the lamps became hot, and leakage did occur there sometimes, and sometimes breakage, when run up to high incandesence, as we ran the lamps.

Adjourned till Monday, the 31st inst., at 1 p. m.

New York, *Nov. 7th,* 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. Man proceeded as follows:

X Q. 1389. On May, 31st, 1878, you filed an application for an "improvement in electric lighting systems," which application resulted in letters patent No. 205,303. This patent was reissued on an application for reissue filed May 14th, 1881, and June 6th, 1882, and is reissued letters patent, 10134. These patents cover a device by which the current is gradually turned onto the lamps. Did you think it important to turn the current gradually onto your lamps?

Same objection.

A. With the larger-size carbons, yes; and where the lamps were filled with gas at atmospheric pressure, or near that with any sized carbon.

1417 X Q. 1390. In lamps such as are shown in patent 205,144, was it necessary to turn the current on gradually?

Same objection.

A. I can only give the same answer as I did before, and add that we did not endeavor to preserve a vacuum in those lamps that I remember, and finally sealed up for use while we were at 43 Centre St.

X Q. 1391. Question repeated.

Same objection.

A. I can only repeat the answer as I have given it to that question, and say that with the conditions under which the lamps were used at 43 Centre St., yes; when filled with nitrogen gas, yes.

X Q. 1392. Is this a correct statement?

"In lighting a lamp such as that shown and described in letters patent 205,144, we found it important to turn on the current gradually."

A. We did find it important to turn on the current gradually, because we were using a lamp filled with gas.

X Q. 1393. Why was it important?

Same objection.

A. Because the carbon was sometimes broken when the current was turned on full force suddenly.

X Q. 1394. At the time you applied for a patent on this switch patent 210,142, did you consider its use necessary for your lamps?

Same objection.

A. I do not remember. I knew we thought it important in this system of electric lighting.

X Q. 1395. You have been interrogated as to the very first experiments performed by you and Mr. Sawyer, with reference to paper and fibrous carbon. The last experiment you described was the taking of a slip of paper soft and porous, filling it with plumbago, pressing the plumbago into the paper and burnishing
1418 it, and then attempting to run a current through. What was the next experiment with paper or fibrous material?

A. The next experiment was filling the paper with graphite by soaking it in water in which graphite was suspended, drying it and repeating until it was well filled with the graphite or plumbago, rubbing it in the paper after dry, burnishing it and pressing it in and then using the slip of paper thus prepared in a lamp or the incandescent portion of an electric lamp, endeavoring to carbonize the paper by the heat produced by the current while in an inert atmosphere used to prevent consumption.

X Q. 1396. Do you remember the size or kind of paper used for that purpose?

A. I think in these first experiments we used ordinary white blotting paper, as to size I cannot recollect. I should think, however, perhaps an eighth or tenth of an inch in width, the thickness of from one to three sheets of the blotting paper, a total length of three-quarters of an inch to an inch between the holders when placed in the lamp about an half inch, perhaps more.

X Q. 1397. In this case was the paper merely used us a support or holder for the plumbago or graphite?

A. No, the intention was to carbonize the paper. We had used pencils of graphite before.

X Q. 1398. Did you get a current through this piece of paper?

A. Yes.

X Q. 1399. What happened?

A. It was heated up and carbonized and broken, as we thought, by the shrinkage due to carbonization.

X Q. 1400. What was the next experiment?

A. We soaked the same kind of paper in different mineral salts and partially reduced the salts, so as to make an electric conductor, using them in the same manner as we used those filled with
1419 plumbago. We heated them up by the passage of the current and carbonized them, but not with as good success as with the slips filled with plumbago. In neither case did the carbons produced last before breaking but a moment or two. Those filled with plumbago lasted the best, and the carbons aside from breakage seemed to be of good quality.

X Q. 1401. What were the mineral salts to which you refer, and how did you reduce the salts?

A. Two of the salts which we used, or tried to, were nitrate of silver and acetate of lead. Perhaps we used others—I don't recollect. I forgot what reaction we used to reduce the salts, probably in the case of the lead the reaction of sulphuretted hydrogen or hydrogen. We did very little of it, however.

X Q. 1402. As I understand you, after soaking, the paper was allowed to dry, and the object of this treatment was to have the paper absorb the mineral salt in order that its resistance might be reduced so as to enable you to force a current through?

A. Yes.

X Q. 1403. What was the next thing you did?

A. The next thing we did, that I recollect, was to carbonize the paper in a close vessel covered with powdered carbon or plumbago in a furnace.

X Q. 1404. Until you carbonized paper or fibrous material by the heat of a fire, do I understand that you had not succeeded in getting a conductor in which paper or fibrous material was employed that was good for anything?

A. No. Rather, up to the time when we carbonized the paper in a furnace in a closed box we had not succeeded in making a practical conductor for an incandescent electric lamp out of the *the* fibrous or textile material. We had only succeeded in producing a carbon suitable for the purpose of such a conductor, but which broke in the process of making it. We practically could not carbonize with the current as we used it. We thought, however, at the time,
1420 that holders might be devised by which the operation might be rendered practical, but we did not go further in that direction; at least I have no recollection of it. We simply succeeded in producing a good quality of carbon, not a good illuminating conductor; with the mineral salts we did not get a good carbon.

X Q. 1405. What information or suggestion had you derived from these experiments which induced you to try carbonizing by fire?

A. We had discovered that the paper made a good quality of carbon.

X Q. 1406. Had you discovered whether it would make a good incandescent conductor?

A. I don't know; we thought it might.

X Q. 1407. What is your best recollection as to how long it was after you went to Centre street that you first tried the carbonizing of fibrous material or paper by fire.

A. I cannot recollect; but taking everything into consideration, an approximation to it would be two or three weeks after we went there. It might have been earlier.

X Q. 1408. Please tell me where you got the iron box in which you did your first carbonization, what material you carbonized, what were the sizes and shapes of the material, where they were put into the box, and where the carbonization was done?

A. The iron box was one got by Mr. William Sawyer, father of William E. Sawyer. It was adapted to use from some piece of iron, I think, that he got from some of the shops at 43 Centre street. The material carbonized, to the best of my recollection, was ordinary blotting paper and card paper, or drawing paper. Some of the sheets cemented together in several thicknesses; the pieces carbonized first, I think, were flat sheets an inch or two square. The box was filled by old Mr. Sawyer and myself at 43 Centre street, and was clamped or wired up after being filled with the powdered carbon and the paper to be carbonized, and then taken by me to my house, 118 Putnam avenue, Brooklyn, and carbonized in my kitchen range. 1421

X Q. 1409. Now, first as to the size and character of the box. Please give me, as near as you now recollect, the dimensions of this box, stating the thickness of the iron, the kind of iron, and how the box was closed or fastened?

A. I think it was a piece of cast iron, with flat ends, with a hole through it lengthwise, from the best of my present recollection, about three inches in diameter. Its outside was, I think, irregular in shape, leaving the thickness of its walls uneven; I should say an average of about one-half or three-quarters of an inch. The ends were closed, making it a box by flat pieces of iron. My impression is that they were of wrought iron, but they may have been cast, and the ends in its first use were, I think, fastened on by wires around the whole thing. I don't pretend that I can recollect with accuracy with regard to this thing such details as you ask me. I simply give the best and only impressions I have in regard to it. I testified in regard to this matter in the interference case between Edison and Sawyer & Man several years ago, when my recollection in regard to the matter was perhaps better than at present. I think that testimony is correct.

Adjourned till Wednesday, the 9th inst., at 1 p. m.

1422 NEW YORK, *Nov. 9th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1410. What, as near as you remember, was the length and diameter of this box?

A. Outside about four inches in width or diameter; inside about three inches in diameter; the length of inside from open end to open end, I should think about two or two and a half inches—it might be three inches.

X Q 1411. How were the pieces of paper and powdered carbon put into the box?

A. First a layer of powdered carbon put into the box, which was leveled off, smoothed down and pressed level with a follower, then a layer of paper laid on top of this powdered carbon, then another layer of powdered carbon smoothed down, leveled off and packed, then a layer of paper on top of this, then another layer of carbon, another layer of paper and another of carbon, until the box was filled. On top of the last layer of paper, powdered carbon packed in until the box was completely filled, and the powdered carbon rose a trifle higher than the top of the box. The covering piece was then put on, pressed down upon the upper open end of the box to close it, and pack in the carbon. The whole was then taken and bound together with wire.

X Q. 1412. Had the paper been treated in any way?

A. No, except where more than one thickness of paper was used; in that case sugar, molasses or treacle was used between the layers of paper, and they were pressed and dried. I do not know, but we may have compressed the other paper before putting it into the box. I do not recollect; we sometimes did so.

1423 X Q. 1413. Was the sugar, molasses or treacle used as a glue solely?

A. Yes.

X Q. 1414. This box, as I understand, you took home and placed in the fire of your range?

A. Yes.

X Q. 1415. What was the make of range in your house?

A. It was a McCann range.

X Q. 1416. What, about, was the size of the fire-box?

A. As near as I could judge (I never measured it) about twenty to twenty-two inches long by nine or ten inches in width, and about fourteen inches in depth.

X Q. 1417. What sort of fire did you use?

A. Coke fire.

X Q. 1418. How long did you leave the box in the fire?

A. I cannot recollect, until the whole thing was heated up as high as I dare to heat it, for fear of melting the box, and kept hot for a considerable time, perhaps half an hour, more or less.

X Q. 1419. Did you sit and feed the fire with fresh fuel?

A. I think so. I know I stayed and watched it until I thought the carbonization was complete.

X Q. 1420. Had you ever carbonized anything before?

A. No, I do not recollect.

X Q. 1421. You say you kept it in the fire until you thought the carbonization was complete; what fact, in your mind, determined this question?

A. I do not know of any fact further than it had been heated up to a bright red heat for a considerable length of time.

X Q. 1422. By considerable length of time what did you mean?

A. I kept it red hot half an hour, more or less.

1424 X Q. 1423. Did you then take the box from the fire?

A. Yes. I took the box off.

X Q. 1424. What did you do with it?

A. I think I put it in the hot ashes under the grate, covered it up and shut up the range, and left it there till the morning. The work was done that evening.

X Q. 1425. As I understand then, the box was in the fire a sufficient length of time to enable it to become red hot, and was kept red hot for half an hour?

A. I should judge so.

X Q. 1426. Was the box heated to a red heat as rapidly as your fire could be made to heat it, or gradually?

A. I do not recollect. I do not think it could be immediately so heated up.

X Q. 1427. Did you open your box at your house next morning, or did you take it to Centre street?

A. No, it was fused together, or the bindings were so fused to it that I could not open it.

X Q. 1428. Where was the box opened?

A. At the workshop, 43 Centre street, by old Mr. Sawyer.

X Q. 1429. Were you present when it was opened?

A. Yes.

X Q. 1430. How was it opened?

A. I don't recollect; I suppose with a file and cold-chisel.

X Q. 1431. You had to cut or file the wires that were wound round the box, had you not?

A. Yes.

X Q. 1432. Were the tops or ends fused to the sides or walls of the box?

A. No; I should think that they were, perhaps, slightly welded; at all events, they were adherent to the box, so that they had to be
pried off or wedged off with a cold-chisel, after the wires
1425 were cut, or one of them, at least, had to be so pried off or
wedged off; I think the other was left on.

X Q. 1433. Do you remember whether it took some time to open the box?

A. A few moments only, I should think.

X Q. 1434. Who took the carbons out of the box?

A. I don't recollect; probably I did it myself, or I and Mr. William E. Sawyer.

X Q. 1435. In what condition did you find the paper that had been put into the box?

A. Some of the pieces were nicely carbonized, and intact. If I recollect correctly, some of the pieces near the open ends of the box were partially consumed at their edges.

X Q. 1436. Did you notice any difference in carbonization between the blotting paper and the card-board?

A. I do not recollect to have noticed any.

X Q. 1437. Did you notice any difference between the carbonization of the pieces that had been glued together and the pieces that were not?

A. I don't remember any; they were thoroughly carbonized.

X Q. 1438. Had you ever seen carbonized paper before?

A. Yes.

X Q. 1439. Where, and when?

A. I do not recollect; I had often seen it.

X Q. 1440. For what use was it intended?

A. I do not know that any use was made of it. It was carbonized for other operations than those for the production of carbon.

X Q. 1441. What did you do with this paper that you carbonized at your house?

A. We cut it up and used it for the incandescent conductor in our lamps.

X Q. 1442. How did you cut the sheets?

1426 A. I don't know whether with scissors or with knife.

X Q. 1443. Did you break many sheets in cutting?

A. Yes.

X Q. 1444. Who did the cutting?

A. I think mostly Mr. William E. Sawyer; he was most skillful at it.

X Q. 1445. Were you present when the cutting was done?

A. Some of it.

X Q. 1446. About how many sheets were taken from the box?

A. I cannot recollect; I should think eight or ten, or more.

X Q. 1447. How many conductors did you succeed in cutting from the sheets?

A. Only a few; perhaps a dozen or twenty, perhaps not so many.

X Q. 1448. Were they cut at the same or at different times?

A. They were cut at different times.

X Q. 1449. Were they all cut before any further carbonization was done?

A. That I don't recollect; I should think not.

X Q. 1450. You say you run some of this carbonized paper to incandescence, do you remember the dimensions of the first conductors you used, or whether they were cut from one sheet or several thicknesses, of from card-board or blotting paper?

A. I do not remember definitely in regard to the matter, further than this, that we used up all the carbons which we had made, in our lamps, of all the kinds that we first made; the impression I have, is that the thickest carbons were the ones we made most use of and found most successful. I could not now state the size of carbons or their length to distinguish these from others that we used.

1427 X Q. 1451. Inasmuch as you had to cut the carbons from the sheets of carbonized paper and could have cut them in any size you desired, and inasmuch as upon the size of the carbon would depend their resistance and the amount of current which would be required to run them to incandescence; and inasmuch as the resistance, the carbons and the quantity of the current required must have had direct relation to the generators of electricity you used, can you give me no idea of the dimensions of the carbon conductors you cut from the paper? You will bear in mind also, that the size and shape of these carbons must have had some close relation to the kind of lamp in which you tried to use them.

A. From the considerations spoken of by you, and from others and possibly from recollection, I proceed to give you my idea of their size and shape. First as to shape. I think these first paper carbons were all cut into straight strips and into low, flat arches, the carbons were too tender to stand pressure between holders and were stretched across tops of the holders in the lamps, their ends resting in slits cut in the tops of the holders. Between the holders the distance was varied from a quarter of an inch to half an inch, or possibly five-eight-s; this gives the lengths of the incandescent portions of the carbon; their width was various, as I should say now from a twelfth of an inch or less up to three-sixteenths, possibly a quarter of an inch; their thickness was the thicknesses of the carbon of the paper from which they were made; some of these first paper carbons, I think may have been bent flatwise, forming an arch rising above the holders, the ends of the arch resting upon the tops of the holders in a slit or slits made to receive them; or upon a ledge cut on the inner faces of the holders upon which their ends rested and held in place by the spring of the carbon. I am not positive as to any of these first carbons being used in this last way, but I think it possible they were.

X Q. 1452. As I understand you, the lengths of the carbons were
from a quarter of an inch to three-sixteenths of an inch;
1428 their width from a twelfth of an inch, or less, to half an inch,
and their thickness the thickness of the sheets from which
they were cut?

A. This is in accordance with the idea I wished, except as to length. I spoke only of the incandescent portion of the length of the carbon; to this should be added the thickness of the two holders, perhaps six-sixteenths of an inch to make their total length.

X Q. 1453. I assume these experiments were conducted with some intelligent purpose; if this be so what was your object in making conductors from the paper which you carbonized?

A. Our object was to get a good and cheap, readily made incandescent conductor and this was one step in the process.

X Q. 1454. Good in what respect?

A. Of pure carbon, and so able to withstand the intense heat of the incandescent lamp conductor.

X Q. 1455. Before carbonizing the paper you knew it could be carbonized?

A. Yes.

X Q. 1456. That if carbonized it would be substantially a pure carbon?

A. Yes, if made of the right kind of paper.

X Q. 1457. That when the sheets or mass were carbonized you could cut from them conductors of such shape as desired?

A. No, we did not know that, but we thought it probable and worth a trial, and we did not know that if we could cut the paper carbons into the size and shape which we desired for incandescent conductors, that they would then have sufficient coherency and strength to be used as such incandescent conductors, or whether they would have other properties necessary or desirable in such conductors.

X Q. 1458. By other properties, to what properties do you refer?

1429 A. Density, durability, elasticity, capability of expansion and contraction without fracture, suitable conductibility or resistance, and the like.

X Q. 1459. I am anxious to understand the object you had in view when making conductors from carbonized paper the first time. You say you knew that paper could be carbonized and that if proper paper were used, a reasonably pure carbon could be obtained, but that you did not know positively whether a conductor could be cut from a carbon sheet, or whether the carbon when cut would have requisite consistency and strength, to hold together under the effect of the current running to incandescence or to be handled and put into holders. Now please state the object you had in view in this first experiment?

A. In the first place, at that time it was extremely difficult to get any pure carbon at all suitable for an incandescent conductor. That we had obtained was difficult and expensive to work and get into shape and size; again, we thought it was not all that was desirable in many respects, such as I have mentioned above and enumerated for such conductor; we thought we might get a good conductor, as we then looked upon it, from the carbonization of paper. I do not think we went into any refinements in regard to it, such as would be considered in the present day, or such as we afterwards came to consider in the manufacture of incandescent conductors. In using the word good conductors I used it only in the sense in which we looked upon it at that time, without going into the particulars or details of the matter, and without pretending that our ideas at that time were definite or fixed as to the best conductor. We knew some properties and some things which we thought desirable, and if it fell in with those we would think it a good conductor, if it proved in our use practical.

X Q. 1460. Had you any preference at that time for a low or high resistance in the carbons, assuming the carbons to be of the same size and shape?

1430 A. I do not know what you mean by a low or high resistance; if you mean relative resistance, I can answer the question.

X Q. 1461. What I wish to know is whether at the time you carbonized this paper first, you had any preference for a low or high resistance in the carbon, due to its character or construction and not dependent on its size or shape?

Question objected to as being one which is impossible for the witness to answer; the question of high and low resistance being purely comparative and undetermined; impossible for the witness to know what is meant by the question and by the expression high and low resistance.

A. I cannot answer that question unless you state to me what you consider in the question a high and what a low resistance. If you ask the question substituting the words lower for low and higher for high, I will answer it.

Adjourned till Nov. 10th, at 1 p. m.

NEW YORK, *Nov. 10th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAX continued as follows:

X Q. 1462. Is it not true that carbons of the same dimensions differ in their electrical resistance due to the difference in structure or character of the carbons?

A. It is.

X Q. 1463. At the time you made this first experiment, had you any preference for a carbon having a higher resistance over a carbon having a lower resistance?

A. Within certain limits I had. Mr. Sawyer had a decided preference for the higher resistance kinds of carbon, perhaps I should
say that it was his opinion at the time that the higher resist-
1431 ance carbons within practical limits of resistance were, or
would prove the best carbons for the incandescent conductor
of an electric lamp. My own opinion upon the subject at the time was not fully formed, and I may say that it was a tentative opinion, that greater conduct*a*bility or less resistance in the carbon would be desirable for the incandescent conductor of an electric lamp, than Mr. Sawyer thought.

X Q. 1464. Do I understand, then, that you and Mr. Sawyer differed then, as to the desirability of a higher or lower resistance in carbons of the same size and shape?

A. Yes; I think we were not agreed.

X Q. 1465. In trying this first experiment in carbonization of paper, had you present in your mind the getting a higher resistance in the carbon due to the character and construction of the carbon?

A. I do not think we had, as a separate thing.

X Q. 1466. Then the object of this experiment was to ascertain if you could get a pure carbon, which would hold together under the effect of the current, which was strong enough to be put into the lamps, and which would last well with the current you were then using, and which could readily be made of any desired shape or size?

A. Yes; I do not recollect now any other purpose we had in mind at the time, but I do not mean to say that other things may not have been thought of by us, but I do not recollect any others.

X Q. 1467. You say from the first paper carbonized, you succeeded in cutting from twelve to twenty pieces, which you tried as incandescent conductors; did you cut the pieces to correspond in shape and size to other conductors you had used?

A. Some of them substantially so, others not at all so; I refer to those that were bent flatwise in the shape of arches, rising above the tops of the holders; we had used none of this kind before and they all differed in the manner of their connection with the holders.

1432 X Q. 1468. Had you ever before tried to run to incandescence a conductor as thin as a conductor made from a single sheet of paper carbonized?

A. I do not remember any, except the paper filled with plumbago.

X Q. 1469. Do you refer to the experiment concerning which you have previously testified?

A. Yes. It may be, however, that some of the carbons made from sheet French carbon and worked down, may have been as thin as the single-sheet paper carbon.

X Q. 1470. Did you succeed in running any of the carbons cut from the sheets of paper carbonized in your first experiment, to incandescence?

A. Yes.

X Q. 1471. All of them, or only some?

A. Only some of them; some of them were of too high a resistance for the current from our dynamo; they were cut too narrow.

X Q. 1472. Which of the carbons could you run to incandescence?

A. Those of least resistance.

X Q. 1473. And which were they?

A. Those of the largest cross-section, those that were thickest or widest, or both.

X Q. 1474. Did you find that the larger the carbon the more brilliant its incandescence?

A. Yes, within certain limits.

X Q. 1475. You say some of these carbons were of approximately the same dimensions as those you had previously used; which were they, those cut from the sheets of blotting paper glued together?

A. Some of them were, and some of them from the single sheet of drawing, or blotter, or card.

1433 X Q. 1476. Did you notice any difference between the incandescence of those carbons, corresponding in size and shape, to carbons of other materials previously used, and such carbons so previously used?

A. I do not remember.

X Q. 1477. What machine were you using at this time?

A. That I don't remember.

X Q. 1478. Did you know at that time, other things being equal, that the incandescence of the carbon would depend upon the resistance of the carbon and the quantity of current conveyed to it?

A. No, I don't think that is an accurate statement; but as the quantity of current was interdependent with the electro-motor force and the resistance in the circuit and also that the work done in the lamp with a given current was dependent upon its resistance, relatively to other resistances in the circuit, it does not seem to me that your statement, to which you wish me to assent, is accurate. We knew that the current remaining the same, the incandescence of the lamp would be increased as its resistance was increased, relatively to the total resistance in the circuit; in other words, that the work would be done where the resistance existed.

X Q. 1479. You say that you do not remember the machine that you were using at this time; can you give me any idea of its electromotive force, or the quantity of current generated by it?

A. No, only that it was sufficient to light up our lamps.

X Q. 1480. Would it light up equally well any and all carbons, irrespective of their size or character?

A. No.

X Q. 1481. Which would it light up the best?

A. Those that we adapted in size and resistance to the current produced.

X Q. 1482. What was the size and resistance best adapted to this current?

A. That I don't know.

1434 X Q. 1483. Can you not give me any idea?

A. I have already given that in the size and shape of the carbons we used. I will add that it frequently happened that we could light up with our current as we adapted the carbon only one, two or three lamps at a time; some of the carbons were such that if we undertook to place a number of lamps in multiple arc, the quantity of current was not sufficient to light them all up; again some of them were of so high resistance that the electro-motive force was not sufficient to pass the current through more than one, two or three of them, when placed in series. Of course the carbons were different at different times and in different lamps.

X Q. 1484. Now, with a given machine you could only produce given results. You don't remember the machine you had this time, and you can tell me neither its volts nor ampere capacity; if you are intelligently conducting your experiments, you must have made your lamps with some reference to your machine and arranged them, if several were used with reference to it. If the resistance of your carbon was a hundred ohms and the electro-motive force of your machine ten volts, the carbon would not become incandescent. On the other hand, if the resistance of the carbon was a fraction of an ohm and the electric force of the machine two hundred volts, and no resistance in the circuit, the carbon would be destroyed. Again, the durability of the carbon and of the whole lamp, of necessity depends upon the relation the lamp bears to the current which is conveyed to it. Can you not tell me, therefore, what work this machine would do in the way of running carbons to incandescence?

A. You forget in criticising our work, which is all the point I see in the question, that the appliances of that day were not those of to-day. You leave out of consideration the fact that we had not

then perfected a system of incandescent lighting and were
1435 working to that end. I have no other answer to make to your question, other than that we did such work as was necessary to run the carbons in the lamp to incandescence, and ascertain what we wanted to know, which was, to know if such carbons could be used. I cannot give electro-motive force, ampere resistance nor volts with any degree of accuracy and can only say that they varied at different times.

X Q. 1485. I take it, you must have known what this machine would do, and what it would not do, and that fact I am anxious to ascertain; now, if it was of such capacity as to run a lamp of a fraction of an ohms' resistance to incandescence, a lamp of a hundred ohms' resistance would not be adapted to this machine; again, if several lamps of the same resistance were *and* arranged in series, and could be run to incandescence, these lamps could not be placed in multiple arc, without a different result. Can you not tell me, therefore, what this machine would do and how you adapted your lamp to it?

Question objected to upon the ground that it is mere repetition, the witness having already stated repeatedly that he does not recollect or know the volts or amperes of the machine and that they had simply a machine or machines to which they adapted their lamps in their resistance, to enable them to determine the practicability of an incandescent conductor made of carbonized paper of an electric lamp.

Question is further objected to, on the ground that it is false in its inferences, in that it assumes that the experiments were not intelligent.

A. I answer, I do not know now, if I ever did know, the capacity of the machines we used. I agree with you, that we did not do impossible things. We did do what I have said we did.

X Q. 1486. Would this machine light up lamps equally well, of low or high resistance, and whether arranged in series or multiple arc?

1436 Question objected to, on the ground that there is no issue of high or low resistance in this case, nor is there any question as to whether the lamps are in series or in multiple arc. If, as a matter of fact, the dynamo was sufficient to prove that a good practical incandescent conductor could be made from carbonized paper, it is sufficient upon the issues of this case. Question being wholly immaterial for the reason stated.

A. All I can say in regard to that is, that we did light up lamps with the machines we used and our other appliances both in series and in multiple arc as well.

X Q. 1487. I am speaking of the machine you had when you first tried to run the paper carbons to incandescence. Was that machine equally adapted to run to incandescence high and low resistance lamps whether in series or multiple arc?

A. I do not remember the machine we had in use with these first experiments of paper carbons. If you wish to say that a machine must be adapted and run to the work required of it, or the work required of it adapted to the machine, I agree with you.

X Q. 1488. I am desirous of getting the facts with regard to these experiments. If you used one machine you must have found that with different arrangements of lamps and different resistances of conductors, different results would follow; this is true, is it not?

A. Yes; and different results would follow, according to the velocity at which the machine was run, the manner of excitation of its field magnet, the extent of that excitation, and the differing resistances in the circuit.

X Q. 1489. Very well. Could you have used a machine for any time without ascertaining what results it would produce?

A. We probably did know at the time the limits in work
1437 of the machines used at the time, and their capacity for different kinds of work, that is, work done by greater or less electro-motive force.

X Q. 1490. You must have known these things if you were working intelligently, must you not?

A. Within certain limits, I think so.

X Q. 1491. Now, if a machine were adapted to run to incandescence a conductor of one ohm's resistance, there being no other resistance in the circuit, you could not take that lamp out of circuit and put in a lamp of a hundred ohms and run it to incandescence, leaving everything else unchanged, could you?

A. Not without changing the velocity of the machine, or increasing its electro-motive force in some way.

X Q. 1492. Then, with a given machine, if you experiment with lamps having carbons of different resistance, you must have known what effect the machine would produce, would you not?

A. Within the limits of variability of the machine we must have known either in electric units of measurement, or in practical manifestation of work.

X Q. 1493. Now you don't remember electrical units, do you remember manifestation of work as to the machine you had when you first tried these paper carbons?

A. Only to the extent I have stated, in the general fact that it heated up the carbons to incandescence; how many, whether one or more, and when more, how arranged, or what resistances were in circuit, I cannot remember.

X Q. 1494. Do you appreciate that, if I could ascertain, either in electrical units, the capacity of this machine, or by a clear statement from you of the work that it would do under given conditions, I would be able then to demonstrate just what could or could not be done by this machine; or, in other words, I would be in a position to verify or demonstrate the incorrectness of your statement?

1438 A. I would be glad to give you every detail, if it were in
my power to do so, knowing that it would demonstrate the truth of my statements. Had I then appreciated, as fully as I now do the value of what we were doing, and the consequent value of

perfect, complete and accurate record of every experiment, I should not be placed in the position of not being able to give details; further than this, it is proper to say that such peculiar, unusual and persistent efforts as have been made in this case to overthrow, deny and belittle the work done by us was not anticipated by myself or my coworker.

X Q. 1495. Do you intend to answer yes to my previous question?

A. No, I do not think it would make any change whatever in this matter, or that you would be able or rather willing to admit the demonstration, if adverse to your preconceived ideas or those of your clients. I admit that if all the details, complete, of our work, were in the hands of parties unbiased and impartial, and sufficiently intelligent, it would enable them to demonstrate the truth of what I have stated.

X Q. 1496. It seems to me that while you testify very positively as to what results you accomplished, your memory is remarkably defective as to the means by which they were accomplished. You were one of the inventors, your coinventor is dead; if I could ascertain from you the facts upon which the general results as to which you testify depend, I would either greatly strengthen your case, or be in a position to show that the general results of which you speak could not have been accomplished with the means at your command. Now I have interrogated you as to a necessary factor in the experiments you performed on carbons, to wit: The dynamo machine used by you in running the first paper carbon to incandescence; if, with this machine, you tried to run to incandescence carbons varying in size and in resistance, due to this variance, or varying
1439 in resistance by reason of different size and difference in the character of the carbon, and if, of these carbons, or any of them, more than one was placed in circuit, or their arrangement varied, it would seem to me incomprehensible that you could not give me some idea of the work this machine would do. Do you wish to occupy this position before the court, that you remember distinctly making lamps containing carbons of different sizes and of different character, and running them to incandescence by this machine; that they were arranged in series and multiple arc; that few or many lamps were placed in circuit; that under all conditions the current was adapted to the lamps; but that you have absolutely no recollection as to what condition of resistance or arrangement the machine was best adapted to?

A. No, I do not want to occupy any position before the court hypothetically suggested by you in your question, containing, as it does, statements, omissions, and interferences not warranted by anything I have said. I wish to occupy before the court just that position which is shown by my testimony and no other. It is not strange that I cannot remember details, and that results best remain in my mind.

Adjourned till November 11, at 1 p. m.

1440 NEW YORK, *Nov.* 11*th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

Witness here desires to add to his last answer the following:

There is another reason, perhaps, why I do not remember more in regard to electrical details, units and capacities. Mr. Sawyer took principal charge of the running of the dynamos, their arrangement, the arrangement of the lamps, the switches, shunts and resistances, and he made the electrical measurements that were made. If he were alive, he might be able to give the details, which I, knowing them probably at the time, but not personally working them out, cannot remember.

X Q. 1497. I have tried to get from you the capacity of the dynamo machine, in order that I may identify the machine you used as closely as possible, having interrogated you previously as to the various machines you used at different times. Please tell me, as near as you can recollect, when paper carbons were first run to incandescence?

A. I have already answered that question, that I did not know; but the nearest approximation I could give, was about two or three weeks after we went to 43 Centre street. It might have been earlier or later.

X Q. 1498. Have you any recollection or impression as to which dynamo machine you were then using?

A. I have not.

X Q. 1499. Does nothing in the experiments enable you to remember?

A. No, I don't remember anything now.

1441 X Q. 1500. You had tried to run to incandescence before trying these paper carbons, carbons varying in size and resistance, had you not?

A. Yes.

X Q. 1501. Had you found in trying such carbons, so varying, that with the same current, different results would be produced upon the different carbons?

A. We did not need to try it to know that.

X Q. 1502. I am anxious to know the fact, so please tell me what you found in practice.

A. That some carbons were of too high a resistance and some carbons of too low a resistance, according to their arrangement, and the current attempted to be used upon them at the time, to be properly lighted up. In explanation of this answer I will add: The currents from the same machines were very variable at different times, on different days and on the same day, due to our want of control of the motive power, and to the variable work going on in the factory, of which ours constituted a very small part.

X Q. 1503. You say that some carbons were of too high a resistance and some of two low a resistance, according to their arrangement and the current attempted to be used upon them. Can you give me no idea whatever as to what carbons were too high and what too low, and what the arrangement was to which you refer—I am speaking of the time you first tried these paper carbons and of the prior period?

A. The same carbons when arranged in series would be or constitute too high a resistance at one time, for us to get a current through them to heat them up—illuminate them; placed in a multiple arc or multiple arc series, they would perhaps be lighted up. Again, when placed in multiple arc, the same number of carbons would make too small a resistance and not be properly illuminated, due to the variance of the current, when a less number of carbons placed in series would be. Now, to distinguish at this time what carbons were used would be impossible for me. Again, we 1442 attempted to use single carbons in a single lamp, which alone constituted too high a resistance for us to get sufficient current through them to heat them up, at one time; when at another time the same carbons would be beautifully lighted up. At another time a single carbon of too large size would not be lighted up by the machine, being too small in resistance, or the current being too small. At another time the carbon would be lighted up. I cannot at this time distinguish what particular carbons these were. Again, we used different qualities of carbon for the conductors, some of higher resistance than we could ordinarily light up, but we sometimes could light up. If you will specify any particular carbon, and will call my attention to it, and I have any recollection of it, I will try to answer more fully.

X Q. 1504. Were you then so ignorant of the capacity of the machine while conducting these experiments, that you could form no idea beforehand when putting a lamp in circuit, what the effect would be, and were dependent upon the trial to ascertain?

A. I have already explained the cause of this variance, in the varying force we were using. Could we know the velocity beforehand at which our machine would run or continue to run? I think we knew enough at the time of the capacity of the different machines we used to adjust the lamps to the current that would be produced, but it is true that I myself personally, at the time, knew very little about dynamo machines. Mr. Sawyer was very much better informed than I was in regard to the matter. We were, I think, at this time, as every one else was, dependent upon the trial of machines to ascertain their capacity.

X Q. 1505. You don't answer my question. I am speaking of a time which your best recollection fixes as two or three weeks after you went to Centre St., and I want to know if you were so ignorant of the capacity of the machines you used as to be able to form 1443 no idea as to the effect it would have on a given carbon when placed in circuit, and were dependent upon actual experiment to ascertain?

A. To this I answer, no. We could and did form an idea of the matter and usually correct ideas, as demonstrated by trial, but we made a great many mistakes.

X Q. 1506. That being so, do you now remember what your use had taught you as to the capacity of the machine?

A. No, not to relate the whole or any considerable portion of what we had learned.

X Q. 1507. I would be satisfied with a very slight idea; so if you can tell me anything in regard to the capacity of the machine I should like it.

A. I cannot undertake to state at this length of time and confining it to that period, or to any particular machine.

X Q. 1508. Could you have ascertained anything of value regarding the value of any carbons used in your experiments with a machine which would at different times produce entirely different results?

A. Yes, I think so. No machine was necessary to learn very much about the qualities of carbons.

X Q. 1509. The effect produced on the carbons is dependent upon the quantity and character of the current conveyed to it. That is true, is it not?

A. Yes.

X Q. 1510. A carbon of too high resistance for the electro-motive force of the machines would not be heated up?

A. No.

X Q. 1511. A carbon of too low a resistance for the electro-motive force would be so brilliantly lighted up as to be destroyed, would it not?

A. Not necessarily. A carbon of too low a resistance for the quantity of current furnished would not be heated up.

1444 X Q. 1512. Assuming no other resistance than the lamp in circuit, the carbon if of low resistance and the current of high electro-motive force, the carbon would be so brilliantly lighted up that it would be destroyed, would it not?

A. Assuming the power used to be sufficient, yes.

X Q. 1513. You, therefore, have to have a carbon, which in its resistance has relation to the current conveyed to it, for the intelligent conduct of any experiments looking toward ascertaining the quality of the carbon, have you not, as an incandescent conductor?

A. No; experiments outside of the use of any dynamo current might be intelligently conducted for determining the quality, character and resistance of a carbon and its suitability for an incandescent conductor for a lamp and without knowing the exact relations of the current used to the resistance of the carbon; intelligent experiment might be conducted with the use of a current by observation of the effect upon the carbon of certain temperatures higher or less high.

X Q. 1514. If you only had a current of five volts electro-motive force could you conduct experiments on lamps having conductors of a hundred ohms resistance?

A. No, you would have to have sufficient electro-motive force to pass sufficient current through the incandescent conductor to heat it up.

X Q. 1515. If you had a current of a hundred volts electro-motive force and lamps of a fraction of an ohm's resistance, could you conduct experiments with but one such lamp in circuit, no other resistance outside the machine being in the circuit but the lamp?

A. No, not practically. You would probably burn up the machine or burst up your lamp, if the power were sufficient. Of course, the experiment could be tried and so much would be learned from it.

X Q. 1516. A person then while using the same machine, but trying carbons of varying size and resistance would of ne-
1445 cessity learn, if not in electrical units, in effects produced,
the capacity of that machine, would he not?

A. If he did not destroy his machine or his lamp he might get some idea of it, and probably would.

X Q. 1517. From a given machine in a given condition with an armature revolving at a given speed, and with a circuit of definite resistance, a current of definite quantity and electro-motive force results?

A. Yes.

Adjourned till Friday, the 18th inst., at 10 a. m.

FRIDAY, *Nov.* 25, 1887.

Met pursuant to agreement of counsel.

Present: Counsel as before, and the cross-examination of Mr. MAX was continued as follows:

X Q. 1518. When trying these first experiments on paper carbons did you burn up your dynamo machine?

A. Whether with these carbons or others I cannot recollect; we did destroy the insulation of the dynamo machine or injure it so that it had to be rewound or repaired.

X Q. 1519. What insulation do you refer to?

A. The insulation of the wires with which it was wound, I suppose the armature. I did not look to it personally, and I think it occurred several times.

X Q. 1520. To what did you attribute, at the time, this injury to the machine?

A. Substantially short-circuiting it; too little resistance outside of the machine.

(Here follows diagram marked p. 1446.)

Complainant's counsel instructs the witness to state, in case he had nothing personally to do with the management and manipulation of the dynamo in the experiments about which he is testifying, to say so upon the record, in answer to any future question of coun-
sel, the object of counsel being to ascertain whether the wit-
1447 ness has or had personal knowledge of the manipulation and
management of the dynamo, or whether he is testifying to
his recollection merely of what Mr. Sawyer told him about it.

Defendant's counsel objects to the instruction above given as improper.

X Q. 1521. Can you remember which machine it was that was injured in this way?

A. I think it was more than one, perhaps more than two or three, but I cannot remember to distinguish; I did not have personal charge of the running of the dynamos, but Mr. Sawyer had and usually run them, and had charge of the running and manipulation of the dynamos and circuits.

X Q. 1522. Was the arc-light machine one of these that was burned out?

A. I have no recollection in regard to that machine being burned out.

X Q. 1523. Your best recollection is that it was some of the machines that you had in your room?

A. That is my impression.

X Q. 1524. From the time you ceased using the arc-light machine in the basement and until you got the specially wound machine, I understand the machines you used were those you borrowed from Arnoux and Hochausen; was it these machines, thus borrowed, that you burned out?

A. We had, while we were at 43 Centre street, whether at this time or later I cannot recollect, other machines, among which was one or more of Weston's; I should think, however, that the machines that were injured were those of Arnoux and Hochausen; my best recollection would be that one or more of them was a borrowed machine, and that also the one we bought of them was injured.

X Q. 1525. Do you remember whether the first machine you had in your room at Centre street was burned out in this way?

1448 A. No; I remember only that it was out of order, or got so.

X Q. 1526. So that it could no longer be used?

A. No; I think we did make some use of it, but it was ineffective or crippled or diminished in efficiency.

X Q. 1527. Was it so inefficient that you had to get another machine?

A. We did get another machine, I don't know whether for this cause—possibly it was, but I do not recollect.

X Q. 1528. Was the second machine of the same make and general capacity as the first?

A. It was of the same general type, whether of exactly the same make I don't know, nor do I know its capacity.

X Q. 1529. After you got the specially wound machine, was it, or any of the machines you had at Centre street, after its delivery, burned out?

A. I have already answered that question as far as I can. I repeat: My impression is that both it and other machines were injured and had to be repaired.

X Q. 1530. Do you remember whether your getting different machines was caused solely by the destruction of the machines you had been using, or was prompted by other reasons?

A. I think it was prompted also by other reasons.

X Q. 1531. Do you know?

A. I believe it was, and am confident as far as one could be at such a length of time, that such was the fact—I think we were trying different machines as to their capacity and suitability for our use.

X Q. 1532. But do you not now remember what capacity you desired, or in what "suitability for your use" consisted?

(Here follows diagram marked p. 1449.)

1450 A. I do not, as these matters were in charge of Mr. Sawyer, and he ran the machines and tested them; I doubtless knew at the time, but do not recollect.

X Q. 1533. You say in answer to question 1516 that a person while using the same machine, but trying carbons of varying size and resistance, if he did not destroy his machine or his lamp, might, and probably would, get some idea of the capacity of his machine. This being so, have you no recollection of the capacity of the machine you used when first trying these paper carbons?

A. I have no recollection of the electrical units, if I knew them. In effects we succeed in passing current through paper carbons and heating them up to incandescence. Some paper carbons that we tried were of so high resistance that we could not get a current through in sufficient quantity to heat them up; in others we did. I am speaking of the first batch of paper carbons.

X Q. 1534. Do you remember whether the machine which applied the current to this first batch was in your room or not?

A. I have stated already that I do not.

X Q. 1535. You do not remember the machine you used in heating up these first carbons; do you remember whether you ever afterwards regarded it as unsuited to carbons made from paper or fibrous material?

A. Not recollecting the machine I could not do so one way or the other. I remember subsequently, and after we cut the carbons to shape before carbonization, having difficulty in getting a current through the carbons in the first instance with the current at our disposal, and I remember rapidly making and breaking connection between the poles of the machine with a file, and with a saw, and with a notched piece of iron, to force the current through these carbons in the first instance.

X Q. 1536. Do you remember whether the machine to which you last refer was the same machine as you used in your experiments on the first paper carbons?

1451 A. I do not.

X Q. 1537. I understand you to remember distinctly two things concerning the trial of these first paper carbons: First, that through some you did not get current in sufficient quantity to heat them up; that others you could heat up—am I right?

A. Yes.

X Q. 1538. Do you remember whether, in the case where the paper carbon did not become incandescent there was any other resistance in circuit outside the machine than the single lamp containing the carbon?

A. I only remember that we had adjustable resistances in the circuits as we ordinarily used our lamps and experimented. These resistances could be diminished to little or nothing or increased to a great many ohms. I cannot recollect the arrangement in our experiments with the first paper carbons. I assume, however, that we had little or no resistance except a single carbon in circuit when the current was first passed through the paper carbons.

X Q. 1539. In those cases where the paper carbon was heated up was there any resistance in the circuit other than the paper carbon?

A. I repeat my last answer. Probably not at first.

X Q. 1540. We then have this fact, as I understand, that whatever machine you used at this time its capacity was not sufficient to run to incandescence some of these paper carbons, or in other words, some of these paper carbons were of too high a resistance for this machine?

A. No, that is not necessarily so; because it assumes that we tried only one machine upon these paper carbons. If we tried more it would be true when the current was not passed through the carbon that the machine then used in that experiment did not have sufficient el-tro-motive force to pass sufficient current through that carbon to heat it up to incandescence.

X Q. 1541. I speak of the machine you used in running the first batch of carbons to incandescence; I have understood you to
1452 say that that machine would run some of the carbons to incandescence, but not others. Have I understood you?

A. You have. I have simply stated that with some of the paper carbons first made we succeeded in heating them up to incandescence with the current we were using at the time without reference to dynamo machines, for I do not recollect them, and that at other times, with some of those paper carbons we did not get sufficient current through them to heat them up. I have not stated, and do not intend to state, and do not know whether we used more than one dynamo machine with these carbons. Furthermore I have stated that with the same machines we got at different times different electro-motive force, for reasons which I have fully explained. Nevertheless it is true, and that is the impression I wish to convey, that some of these paper carbons we thought were of too high resistance for practical use with the current we had.

X Q. 1542. Well, which were these paper carbons?

A. They were the smallest and longest ones; those of highest resistance.

X Q. 1543. Please tell me as near as you can the length and cross-section of the carbons to which you refer?

A. I have already given them as near as I can recollect. Do you mean those of highest resistance?

X Q. 1544. I mean those which you "thought were of too high resistance with the current that we (you) had"?

A. They were less than a thirty-second of an inch in diameter in one direction, of the thickness of carbonized blotting paper, of a cross-section at right angles to this, approximating one-sixteenth of an inch, perhaps less than that, and of a length of an inch or more. These dimensions cannot be accurate, and I speak from examination of a gauge and these carbons, in my mind's eye, after nearly eight years; I give you simply my judgment of the matter at the present time.

X Q. 1545. Did you ever do any further carbonizing at your house than the single instance you have mentioned?

1453 A. Yes.

X Q. 1546. How long after this time was it?

A. Right away, within a day or two.

X Q. 1547. Did you use the same iron box as previously?

A. Yes, and others.

X Q. 1548. Do you mean you used two boxes in the second carbonization?

A. I cannot tell whether I used two boxes in the second carbonization or in subsequent carbonizations; I used more than one in the fire at the same time, and made a good many carbonizations within a week or ten days.

X Q. 1549. What did you carbonize in the second carbonization?

A. After the first carbonization we cut paper of different thicknesses, some of them cemented together, into shapes for incandescent conductors, of different shapes and sizes and lengths, and I think we cut slips of wood—my impression is, first, of willow into shapes, sizes and lengths for incandescent conductors, and I think, in the second carbonization, the box or boxes contained the wood and paper in the same box.

X Q. 1550. Had the paper or wood been treated in any way?

A. No further than where the paper was cemented together, to give it greater thickness; some carbonaceous material was used as a cement, and that the paper was pressed and consolidated.

X Q. 1551. Do I understand that in this second carbonization, which was done at your house, the material to be carbonized was cut to the desired shape and size of the conductor?

A. Yes, to the desired shape and size to make a conductor.

X Q. 1552. Did you then prefer any special shape or size, or any general shape or size?

1454 A. We preferred a shape that, when the conductor was placed in the holders it would rise above them, but, as to size, we made the blanks of various sizes and various lengths for trial, and we did not make them all of the curved form to rise above the holders, but many were straight; our opinion perhaps was tentative as to what would prove best at this time.

X Q. 1553. What kinds of paper did you carbonize at this second trial?

A. Only white blotting paper; it may have been that some card or drawing paper was used at this second trial.

X Q. 1554. Do you remember what your reason was for using only blotting paper at this second carbonization?

A. Yes; we thought that the white blotting paper, not having been treated in its manufacture with any other substances, and being pure cellulose, would make a purer carbon.

X Q. 1555. Describe the willow you carbonized this second time, what kind of willow it was, and how it was cut, and what your object was in carbonizing it?

A. The willow was ordinary willow, such as used by basket-makers; was cut out in straight pencils; the object was to make an incandescent burner of willow charcoal.

X Q. 1556. Had you any theory on the subject of what the qualities of such substance would be?

A. I had an idea that willow charcoal was most free from impurities; that was the reason for my selecting willow.

X Q. 1557. Your recollection is, as I understand, that this second carbonization was within a day or two after the first; did you carbonize again at your house, and, if so, how soon was the next carbonization?

A. I followed up these carbonizations with a good many more at my house; I think they were all done at my house, but some may possibly have been done in the furnace at 43 Centre street.

1455 X Q. 1558. You don't tell me how soon the third carbonization was after the second.

A. I don't recollect.

X Q. 1559. Well, about how long?

A. In my second carbonization, or in one of those made very soon after the first, I burned up one of the boxes and spoiled the carbons, and I very soon spoiled the first box that I used; I should think the third carbonization, from recollection, was within a week or ten days of the first.

X Q. 1560. What did you carbonize the third time?

A. I should think only white blotting paper and willow wood, but I cannot undertake to remember the minute details of this work.

X Q. 1561. Was the material carbonized treated in any way?

A. No, except where cemented together and pressed.

X Q. 1562. Was the material cut to the desired shape and size of the conductor before carbonization?

A. Yes.

X Q. 1563. Had you at this third carbonization determined on any general size or shape?

A. I don't think further than I have before stated.

X Q. 1564. On how many separate occasions did you carbonize at your house while the laboratory was at 43 Centre street?

A. I cannot recollect; a good many; I burned up several boxes, I got some wrought-iron boxes and covered them with clay and finally used crucibles, luting their covers down with clay and making a small vent for the escape of gases?

X Q. 1565. What would be your best recollection as to the number of times you carbonized at your house?

A. I won't undertake to state; I should think twenty-five or thirty times and probably more, but I cannot undertake to recollect at this length of time.

X Q. 1566. Was it your habit to pack the boxes at 43
1456 Centre street, take them to your house, carbonize them and
then take them back to Centre street?

A. With the metal boxes I think that was done, but not altogether with the crucibles.

X Q. 1567. What material, if any, other than paper and willow wood did you carbonize at your house?

A. I carbonized a variety of woods, every kind that I could get hold of; I also carbonized strings of different kinds and different materials; I think, broom-corn; woods cut into strips and bent; different shapes of paper; some woods in the form of veneers worked down extremely thin and cemented together with the fibres running in different directions; excelsior, I think; manilla; I don't now recollect all the things that I carbonized; I also recarbonized after this different things after saturating them with pure white sugar after the first carbonization.

X Q. 1568. What object had you in view in carbonizing these different substances?

A. We wanted to get pure carbon that would be sufficiently elastic and strong and not liable to break, and that would endure the strain put upon the incandescent conductor of an electric lamp. Perhaps it would be summed up in calling it a structural carbon, that is, one in which the material to be carbonized had been formed by nature, and in which the natural form was being preserved after carbonization, we thought some advantages might be derived. To give an illustration of the subject-matter of our thoughts, we had procured and we made carbons for the incandescent conductor of an electric lamp made of pulverulent materials in which, when pressed into form, the arrangement was heterogeneous. These carbons we found, or thought we did, were liable to fracture and disintegration by the current, and we were trying to get a carbon that would stand "the racket," as Sawyer said. A further illustration:
The mineral carbons and other made-up carbons were so far
1457 rigid that by the least flexture or bending they were broken,
while the vegetable carbons and those made especially of paper could be bent to a considerable extent without breaking, showing their greater flexibility and elasticity; the mineral carbons and those made-up carbons were amorphous in their structure while the others were fibrous.

X Q. 1569. You say you carbonized all these substances at your house in your cooking range in the hope of getting a pure carbon which would be elastic and strong, and not liable to break; of the different materials you carbonized did you regard them all as equally good?

A. No.

X Q. 1570. Did you try them all in your lamps?

A. I think that we tried all that I have mentioned, more or less.

X Q. 1571. Did you try all the different shapes and sizes?

A. No, I don't think so; of the different materials, I think, on reflection, that we did not try in the lamps the carbons made from wood veneers; I think they showed themselves defective without trying; I do not know that while at 43 Centre street, we tried the manilla fibres, pure and simple; my impression is that they were too fine, and I cannot be certain that we tried all the carbons made from different kinds of wood in the lamps but most of them we did.

X Q. 1572. Which of these various materials did you consider you got the best of carbon from?

A. They were three kinds at this time; my recollection is indistinct in regard to one of them, whether the trial of this one was preferably satisfactory to us when at 43 Centre street, or afterwards in the fall of 1878; the three from which we met the greatest success and which were preferred by us, in the order of preference at the
time, were willow-wood carbons, paper carbons, and carbons
1458 from broom-corn, if our preference was established for that
while at 43 Centre street, of which I am in doubt.

X Q. 1573. Now of paper carbons, which paper did you consider made the best carbons?

A. White blotting paper we had the most success with.

X Q. 1574. Did you ever treat the material in any way before carbonization?

A. Yes, we soaked the paper sometimes in sugar solution and we always compressed it. I think we also soaked different woods in sugar. I am not confident in regard to it, but I think we also impregnated the materials with different carbonaceous substances, such as oils, glues, etc., to reduce the resistance of the carbons after they were carbonized. This was not done till after the first few carbonizations at my house.

X Q. 1575. You say you treated the materials before carbonization to reduce their resistance. Had you found the carbons of too high resistance?

A. We so treated some of them, and we had found that some of our carbons were of too high a resistance for our currents, and we also treated some of them in this manner for another purpose, that is, to make them more rigid; that is, where they were to be used as straight pencils.

X Q. 1576. And you found that straight pencils of fibrous material were not sufficiently rigid for conductors?

A. That is perhaps too broad a statement. They were not sufficiently rigid to use in some of our lamps.

X Q. 1577. Were the only materials that were thus treated before carbonization these which would be of too high a resistance, or straight pencils whose rigidity you desired to increase?

A. No, I should think not. At first we crushed the ends of some
— the paper carbons between the clamps in which they were
1459 held. To make the carbons harder and less easily crushed
we soaked them in sugar, some of them before carbonization.

X Q. 1578. Did you ever adopt this treatment before carbonization as a general practice?

A. No, I don't think we did.

X Q. 1579. Did you consider it an *an* advantageous thing to do?

A. Not more so than the treatment after carbonization.

X Q. 1580. Question repeated.

A. For the purpose that we sought to attain, that I have mentioned, it was advantageous.

Adjourned till Monday, the 28th inst., at 10½ a. m.

MONDAY, *Nov.* 28, 1887.

Adjourned till Tuesday the 29th inst., at request of defendant's counsel.

TUESDAY, *29th Nov.*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1581. I understand that where you wished to reduce the resistance, you treated material to be carbonized in the manner described, and also where you desired to use the materials as straight carbons, and you desired greater rigidity it was so treated; what other material was treated in this way?

A. Your statement needs correction. I simply said that we sometimes did this for the purpose stated, not that we did it always when we wanted to attain those ends, as your statement implies. I
do not recollect what other substances we treated in this way;
1460 we frequently did it, but I cannot bear in mind what particular substances were used, further than I have stated.

X Q. 1582. Is it then the fact that you sometimes treated the material before carbonization, and at other times did not?

A. Yes, and I will add to save further question, that we sometimes treated them in a similar manner after carbonization, and recarbonized after treatment and sometimes did not.

X Q. 1583. What I want to get at is, in what cases and for what reason you treated before carbonization, and in what cases and for what reason you did not treat before carbonization?

A. No further than I have already stated.

X Q. 1584. Did you ever form an opinion as to whether it was a good thing to do?

A. We formed an opinion that it accomplished the results we desired in practicing it—of making the carbon more dense, harder, and of less resistance, and that it was a good thing to do when we wanted to accomplish these things.

X Q. 1585. Question repeated.

A. I have no further answer to it; I don't think we had any further opinion in regard to it than I have stated.

X Q. 1586. You never adopted this as a practice, I understand?

A. We certainly did practice it, if that is what you mean.

X Q. 1587. You had not at this time, as I understand you, decided upon any desirable resistance for a conductor of any given shape and size?

A. No, I do not think we had, except in connection with the particular system and other things with which it was to be used.

1461 X Q. 1588. Do I understand that you had decided this question with reference to the system that was to be used?

A. Most assuredly we had decided that the resistance must be a practical one for the current available, but I do not think we had decided in regard to the electro-motive force as a usual thing, which would be most suitable in a general system for use of incandescent lighting, and upon that, as a general proposition, would depend the resistance of the conductors to be used, taken in connection with the arrangement of the lamps.

X Q. 1589. Had you determined anything more then, than that the resistance of the lamp must have relation to the current conveyed to the lamp?

A. In regard to what do you ask the question? Specify; do you mean in regard to the resistance of the conductor alone?

X Q. 1590. Question repeated.

A. I don't know what you mean by "more," what do you mean by "more" in regard to what?

X Q. 1591. I am trying to ascertain the object and extent of your treatment of paper or fibrous material before carbonization, and what, if any, decision you had come to in regard to the advisability of doing so; you say in some cases you did treat them, in others you did not; you practiced it but did not adopt it as a practice; that it had the effect of reducing the resistance of the material, but that you had not determined upon any desirable resistance for a conductor of given shape or size; if I understand your answers, it would seem that you have no opinion whatever on the subject of its value, but that you only used it as an expedient in certain cases; is this correct?

A. If you will consent to take my testimony in the words in which I give it, instead of going on to state what I say, in your own fashion, and coupling great numbers of things together without accurately stating what I say, and ask me whether it is correct or
1462 not, we will get along better and faster; you state that you are
trying to ascertain, first, the object of the treatment of paper or fibrous material before carbonization; second, the extent of that treatment; third, what, if any, decision we had come to in regard to the advisability of doing so; I have fully answered in regard to the first and third things you say you are trying to ascertain; if you now ask me in regard to the extent of our practicing that thing as a fact, I can answer it; if I answer the question you put to me, I shall have to go back and correct your statement of my testimony.

Answer objected to as irresponsive.

X Q. 1592. Was this treatment before carbonization, used only as an expedient in those cases where you desired to make the resistance of the conductor less than it would be if the material were not treated?

A. No; it was used also for another purpose.

X Q. 1593. What other?

A. To make the carbon more dense and harder and better able to endure the clamps of the holders and other manipulation of the conductor.

X Q. 1594. Any other object?

A. I do not remember any other now.

X Q. 1595. Would you, then, in those cases where you desired to obtain these objects treat the material, and in other cases not treat it?

A. Yes.

X Q. 1596. Did you ever reach any conclusion as to whether it was desirable to, in some way, increase the density and hardness and decrease the resistance of a carbon made from paper or fibrous material from what it would be if the material were simply carbonized and used without any treatment?

A. Not as an abstract question in and of and by itself; we did not reach a positive conclusion or opinion that our electrical treatment of carbons, which did reduce resistance and increase
1463 the density and hardness and decrease the resistance of a
carbon made from paper was desirable, and we also had an opinion that it was a convenient way and useful, in making certain carbons, to treat them before or after carbonization in carbonaceous solutions or liquids, and this did reduce resistance, and increase hardness and density.

X Q. 1597. To what extent did you treat material to be carbonized before carbonization, in your experiments?

A. I cannot at this length of time remember with accuracy, to state the extent of the treatment before carbonization, as distinguished from the treatment after carbonization. We sometimes did one and sometimes the other and sometimes both. (I am referring to the time at 43 Centre street to which I understand you to refer), and taken together we treated, I think, more considerably than we left untreated. I think, a large majority of our carbons were so treated; almost all I should think, while at 43 Centre street, but not all.

X Q. 1598. Almost all then were treated either before or after carbonization?

A. I think so; either by the treatment of the suguar or carbonaceous solution, or by electrical treatment, in a hydrocarbon atmosphere, liquid or gaseous, both.

X Q. 1599. This latter was according to the process of the Sawyer and Man patent, to which we have referred?

A. Yes, and we frequently treated the same carbons in both ways.

X Q. 1600. Who assisted in this treatment either before or after carbonization?

A. The electrical treatment was almost always done by Mr. Wm. E. Sawyer. The other treatment I frequently performed, and I think I frequently had the assistance of all three of the Sawyers, Mr. Wm. E. Sawyer superintending it when I was absent.

X Q. 1601. Were you usually present when the electrical treatment was done?

A. I was sometimes present and sometimes not. The 1464 bulk of the time I was not at Centre street, and the work went on whether I was present or not.

X Q. 1602. Did anybody assist you in the carbonization at your house?

A. Yes; the servant usually assisted me, and once or twice I think Mr. Wm. E. Sawyer was over there. Sometimes I had no assistance.

X Q. 1603. Who was the servant to whom you refer?

A. I really couldn't tell. She is not with me now; she simply built up the fire for me and handed me things, and so on.

X Q. 1604. You say you preferred, of the various materials you carbonized, first, willow carbon and second, paper carbon. What were the qualities in willow carbon that made you prefer it to carbons made from other fibrous materials?

A. I do not know anything except that we were more successful in the use of it in our lamps while at 43 Centre street, and could easily get it into the shapes and sizes we wanted.

X Q. 1605. What properties did you find in paper carbon that made you prefer it to other carbonized, fibrous material, with the exception of willow?

A. We thought that the arrangement of the fibres in the paper carbon was an advantage, and we also thought that it being already of the size, or sizes, in one direction, which we desired, being in flat, thin sheets, or easily made or selected of the dimensions in one direction, which were required for the incandescent conductor, and easily put in shape or cut in shape for the conductor before carbonization, and both the willow and paper carbons being pure carbons, or substantially so, that these were most advantageous, and they proved the most successful of the carbons in use in our lamps. We also thought that their fibrous structure, retained after carbonization, was an advantage. We also found that these substances were best carbonized without fracture, except some fibres and 1465 strings of which we made little use at this time, except by way of experiment.

X Q. 1606. What was the arrangement of the fibres in the paper carbon, to which you refer in your last answer as an advantage?

A. They were all laid in one plane.

X Q. 1607. Is this true of all papers, or only of certain kinds?

A. It is generally true of all; not absolutely true of any, but approximately.

X Q. 1608. What was the advantage which you attributed to this arrangement of fibres?

A. That they, the fibres were less easily broken in the direction of their length than in the direction of their cross-section, more of the fibres of paper carbon would lie in the direction of the length of the incandescent conductor than would be the case in a substance not reduced to sheets, and therefore they would not be so easily broken or so fragile.

X Q. 1609. Aside from any ease of cutting or shaping to the desired size, what were the properties possessed by carbon made from willow as a material which you considered advantageous?

A. Simply that the fibres run in the direction of the length of the conductor, and that it was a pure material, made a pure carbon, that is, aside from the convenience of getting it into shape.

X Q. 1610. Would not the fact whether the fibres of the material ran in the direction of the length of the conductor depend on how the willow was cut?

A. Yes; but we cut them to make them run in that direction; the same is true to some extent with paper; the fibres mainly run in one direction, and we cut them to avail ourselves of this fact.

X Q. 1611. You speak in your 1605th answer of an advantage due to the retention of the fibrous structure after car- 1466 bonization. In what did the advantage referred to consist?

A. Strength and resistance to fracture in the directions of the length of the fibre, and possibly in the directions at right angles, or other directions, possibly also elasticity or flexibility, or both.

X Q. 1612. How long had you been experimenting with paper or willow carbon before you concluded that they were preferable to other carbon?

A. I cannot tell. I know that when we left 43 Centre street we thought they were preferable to all we had tried of fibrous carbons.

X Q. 1613. How long was it before you made up your mind that the fibrous was superior to the non-fibrous carbon?

A. I don't know that as carbon I ever made up my mind to that effect.

X Q. 1614. As the carbon for an incandescent conductor?

A. I have already testified very fully in regard to this subject-matter, and I do not wish to be misunderstood in regard to it; I only stated, in substance, that the incandescent conductor made from fibrous or textile material, taking everything into account, including purity, practicability, cheapness and ease of manufacture, of proper size and length, was, on the whole, the best that I had known of.

X Q. 1615. Of the carbons tried in Centre street the great majority were not fibrous carbons?

A. I think not.

X Q. 1616. They were French carbons, were they not?

A. They were mineral carbons, so called, and deposit carbons.

1467 X Q. 1617. At the time of leaving Centre street had you any preference for fibrous carbons over non-fibrous carbons?

A. At the time of leaving Centre street I had an idea that in the end the fibrous carbons would prove the best to use for the incandescent conductor of an electric lamp, but my mind on that subject-matter I do not think was fully made up; that is, I had not demonstrated to my satisfaction that such was the fact.

X Q. 1618. What were Mr. Sawyer's views?

Objected to as incompetent.

A. I do not think that at that time there was any difference of opinion between us about the subject-matter; perhaps I was strongest in my views about it.

X Q. 1619. Do you mean that Sawyer thought that fibrous material would prove the best?

Objected to as incompetent.

A. I mean to say that I think Sawyer thought that our incandescent conductor made from fibrous material would prove a good conductor; whether he thought as I did, that it would or might prove the best, I cannot say.

Adjourned till Wednesday, the 30th inst., at 1 p. m.

1468 NEW YORK, *Nov.* 30, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN continued as follows:

X Q. 1620. Referring to the treatment before carbonization, please to state what the general nature of the carbonaceous solution with which you soaked the paper was, what your method of thus treating it was, what effect the treatment had, and what materials you thus treated. You have spoken also of pressing and consolidating the material before carbonization; will you please explain how this pressure was effected, and what the effect of such pressure was on the material thus pressed?

A. The material with which we usually treated the fibrous substances to be carbonized before carbonization was a solution of refined white sugar—we may have used, and I think we did, isinglass or glue and oils; whether the oils were at 43 Centre street I can't recollect; we soaked the fibrous substances in these solutions, dried them, resoaked them, until we thought we had got them fully saturated with the sugar or other carbonaceous material or sufficiently filled with it for the purpose we intended; the effect was to fill the pores of the substance more or less with the carbonaceous material as we desired; after thus filling the pores, and while the material was in a condition to do so, we pressed it between smooth plates in a screw press or vice to consolidate it; we carefully afterwards dried it, sometimes in a muffle, to drive off the water, carrying the heat in the drying process as far as we could without charring the material; the substances we thus treated were paper and strings of different kinds and wood, except that we did not press the wood, and we did not treat before carbonization with the carbonaceous solution, but a small part, comparatively very few;
1469
usually when treated in this way at all, they were treated after the first carbonization, but we usually pressed or consolidated the fibrous materials, paper and other kinds, except woods, before carbonizing them or hammered them for the same purpose on a smooth anvil with a strong hammer; I think also we stiffened

some of the strings that we carbonized with starch instead of sugar and the effect was to render the carbon formed from the material more dense and for the same size of higher conductability or less resistance; it was also harder and better suited for handling and manipulation without breakage as we thought.

X Q. 1621. In some instances, as I understand you, the material was resoaked and recarbonized several times?

A. It was.

X Q. 1622. Now, as I understand, the material was treated after carbonization either by the electrical treatment, solution or both, the electrical treatment being your patented treatment?

A. Yes.

X Q. 1623. When did you begin this electrical treatment with reference to your experiments on paper?

A. With our first carbonizations of paper we put them in a bath of hydrocarbon gas or in a lamp containing hydrocarbon gas to try them; before then we had discovered the electro deposit of carbon upon an incandescent conductor heated up in an atmosphere of hydrocarbon gas, but I do not think that we put the first paper carbons into this atmosphere in the first instance with the intention to treat them, but because it was the most convenient way of trying the carbons, the atmosphere of the lamp or vessel in which they were tried being readily supplied, resupplied and kept up from the gas pipes; we knew then that their resistance would be reduced rapidly by this treatment or use.

1470 X Q. 1624. Am I correct in understanding that all the carbons, irrespective of the kind of fibrous or textile material from which they were made, were treated by this patented electrical process?

A. No, not all; but it was our practice usually to treat them and we treated nearly all of them and thought them improved by treatment, but we also treated them sometimes and frequently in order to get conductors of the same electrical resistance.

X Q. 1625. As a *a* rule this electrical treatment was done by Sawyer?

A. Yes, sir.

X Q. 1626. In treating these fibrous carbons by this electrical process, to what extent was this treatment carried on; I do not refer to the number of fibrous carbons treated, but to the extent of the treatment of such as were treated?

A. In some cases the treatment was very slight, hardly perceptible except under the glass; in other cases the treatment was carried on and repeated until sufficient deposit of carbon had been made to serve as a conductor after the removal of the original carbon and the deposit-carbon conductor thus formed was sometimes by us split or cut into two or three conductors lengthwise and retreated to make them of the size and resistance required; the treatment which we gave to the carbon was all the way from the extremely slight treatment I have first mentioned to the extremely extensive treatment I have last mentioned; I do not remember carbons made from any other fibrous substances than paper and wood with this extremely large treatment and most of those so largely treated were of wood carbon, some few of paper carbon cut in the form of arches.

X Q. 1627. In some cases I understand you treated to such an extent only as would make several carbons of uniform resistance and in other cases would treat for the purpose of improving the carbon irrespective of the question of resistance?

1471 A. Yes, and in some cases to manufacture conductors of pure-deposit carbon.

X Q. 1628. Where you desired simply to improve the carbon, the question of resistance being not involved, what was the extent of the treatment?

A. We tried all kinds and extents of treatment for the purpose of improving the conductors from the slightest to the highest.

X Q. 1629. Was there any extent of treatment which was deemed best while you were at 43 Centre street?

A. Yes, I think there was; we had found while we were at 43 Centre street, I think, that the deposit carbon had a tendency to fly to pieces or break like glass when suddenly heated up; we had found that carbons largely treated with deposit carbon were liable also to fly to pieces in the same manner, when suddenly heated up; or if the current was not turned on to them gradually, but that fibrous carbons less treated were not liable to do so; for this reason we thought it best not to treat the carbons too much, but I do not think I could describe, at the present time, the extent of treatment that we thought best; the extent of the treatment that we thought best simply gave a silvery or lustrous appearance to the carbon, instead of being black, as it was before treatment.

X Q. 1630. Was the resistance of the carbon reduced in proportion to the extent of the treatment?

A. Yes.

X Q. 1631. I quote from the testimony of Mr. Sawyer, in the interference between Edison and Sawyer-Man, cross-question and answer 42:

"X Q. 42. As a matter of fact, about how much was the resistance reduced?

"A. Mr. Man's idea and mine upon that question of resistance began to differ. That is to say, my theory that the most perfect electric lamp would be one in which the incandescent con-
1472 ductor had the highest resistance and the least transverse mass was gradually abandoned by myself, while largely retained by Mr. Man; my present theory being that the most perfect electric lamp is one in which the incandescent conductor has not only the least transverse mass, but the least resistance; I soon began to reduce the resistance of my carbons to as low as an ohm; at present I make them only ¼ ohm, therefore I would treat the carbons so as to obtain a heavy deposit; judging from the difficulty in getting the current through some of Mr. Man's carbons, treated according to his ideas, they must have had as high as 100 ohms resistance, but I don't recollect whether we made measurements of any particular ones; answering the question directly, I should say that Mr. Man reduced the resistance in his carbons from fifty to

seventy-five per cent. by the treatment referred to; this is an estimate, and not the result of measurements."

Is it your recollection that Mr. Sawyer's statement in the above testimony is correct?

A. I have no means of ascertaining or judging; I assume that Mr. Sawyer's statement, in regard to the reduction of resistance, has reference to an average or usual thing; if it is taken in that sense, I could not say that Mr. Sawyer's statement is not correct, but I would judge, and I think I know, that in many cases the resistance of conductors treated was not reduced either fifty or seventy-five per cent., nor even three or five per cent., but I do not understand that Mr. Sawyer was speaking of anything but average practice.

X Q. 1632. Sawyer, as I understand, actually did the treatment; do you know the extent to which he usually treated where the desire was to improve the carbon?

A. Mr. Sawyer usually did the treatment, but I think not always—almost always; he frequently treated carbons while I was present, and under my suggestion as to the extent of treatment; as I said before, I have no means of judging of the extent of average treatment, or at least nothing occurs to me now by 1473 which I can satisfactorily to myself make such judgment; I do not mean to criticise Mr. Sawyer's statement of what he thought it was at the time when he gave that testimony, and assume that he gave it as nearly as he could correctly from his then recollection, and the matters called to his attention by questioning; I, therefore, would acquiesce in Mr. Sawyer's statement of his average treatment, but I could not say what actual treatment Mr. Sawyer gave at different times, for the purpose of improving the conductor, as any treatment would, as we then considered, be an improvement.

X Q. 1633. Was there no point at which you considered the treatment had shown the most beneficial effect?

Adjourned till Monday, the 5th day of December next at 10½ a. m.

MONDAY, *December* 5, 1887.

Adjourned till Tuesday, the 6th inst., at 10½ a. m.

NEW YORK, *December 6th*, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN continued as follows:

Witness answers the last question of the previous session:

A. There was a point at which we considered the treatment most beneficial; as I have stated, the treatment could be carried to the extent of making the conductors substantially of pure-deposit carbon or like one of pure-deposit carbon; now we considered that the deposit carbon as carbon was the purest and best carbon, but conductors made of such carbon were in practice liable to objection, principally for the reason that the carbon being amorphous and dense like glass or possibly crystalline in structure was liable to fly 1474 to pieces and break as glass does when suddenly heated up, especially if the carbon was of any considerable cross-section and of less or very small cross-section was liable to fracture in handling and manipulation as well as in use in the lamp; for that reason, as I have stated and for the other reasons I have stated, among others ease and practicability of manufacture and cheapness, we preferred in practice a fibrous carbon which was not liable to fly to pieces or break when suddenly heated up; the point then which we considered most advantageous in treatment of the fibrous carbons was that extent of treatment, which, while driving out the occluded gases and purifying the fibrous carbon in the treatment, would not interfere with or destroy the fibrous structure of the carbon, but would leave it still a fibrous or structural carbon with nothing but pure carbon added to it and that not to an extent to interfere with the advantages of the fibrous or structural character of the conductor, nor to render it liable to the disadvantages of the deposit carbon, of which I have spoken; this condition being observed there was another point in the treatment having reference to the resistance of the conductor; first, to treat to a sufficient extent to render the resistance of the conductor uniform throughout its length, and secondly, to conform the resistance of different conductors to the same standard so that they would be equal or substantially so in resistance.

X Q. 1634. What were the advantages of the fibrous or structural character of the carbon which you desired to preserve?

A. I think I have pointed out these advantages fully before; they were mainly as I conceived them, flexibility, elasticity and strength, due to the fibrous arrangement, possibly to the structure of the material of which the carbon was made, being produced by a process of nature and some arrangement of molecules or atoms in such process.

1475 X Q. 1635. Was the treatment carried on to an extent sufficient to fill up the pores of the carbon or coat its surface?

A. Yes, to some extent, but that extent in the use of our fibrous carbons, as fibrous carbon conductors, was not carried so far as to completely or considerably fill up the pores, and after treatment the appearance of the carbon as to size, dimensions and fibrous character, remained apparently the same as before treatment, but the carbon was rendered more dense and harder; and had under the glass a lustrous or silvery appearance; in cases where we desired to render the carbon more of the character of the deposit-carbon conductor, the treatment was carried further, the pores were more filled up; in some cases as fully as we could do so, and the conductor was increased in size; these we considered substantially deposit-carbon conductors, and they were to some extent liable to the objections of which I have spoken of deposit-carbon conductors, but not as liable to those objections as conductors made solely and entirely of deposit carbon.

X Q. 1636. In this treatment were the pores filled up before the surface of the carbon became coated?

A. In the treatment the first and most rapid action was at that point of the conductor in its length having the highest resistance; the coating on the conductor went on evidently upon the individual fibres, whether within the body of the conductor or lying upon the outside of the conductor; if the treatment was properly conducted, when the treatment was carried so far as to bridge over the spaces between the fibres, or substantially bridge over such spaces, the coating or deposit of carbon went on only upon the outside of the conductor, and if the treatment were not properly conducted, or was conducted for that purpose, the coating would bridge over between the outer fibres of the conductor almost immediately, and the pores or spaces between the fibres would not be filled up.

X Q. 1637. Then, as I understand you, the treatment 1476 would fill up the pores and coat the outside, or coat the outside and not fill up the pores according as the treatment was conducted?

A. Yes, except that in any treatment there must have been some filling up of pores, but the process as a whole would be as I say.

X Q. 1638. Which did you do in practice?

A. We did both.

X Q. 1639. Which was the proper way of treating?

A. Both were proper, but for different purposes. For the purpose of producing or improving the fibrous conductor, the first method of treatment was the proper one, carried only to the extent I have mentioned, as the best for the production of fibrous carbon. For the purpose of producing a conductor of pure-deposit carbon, the process by which the deposit went on mainly on the outside of the conductor was the proper one, and for the purpose of producing a carbon, having mainly the character of a pure-deposit carbon, but with a core of fibrous carbon left in it, the second process, by which the deposit went on mainly on the outside of the conductor, was the proper one.

X Q. 1640. As I understand then, by the use of this treatment you obtained three characters of carbon: first, a fibrous carbon treated as you describe; second, a fibrous carbon treated to such an extent that the original carbon simply acted as a core for a shell of deposit carbon; and thirdly, a deposit carbon pure and simple, from which the fibrous carbon was removed?

A. Yes.

X Q. 1641. Was the second carbon liable to fracture or fly to pieces?

A. More liable than the first and not as liable as the last.

X Q. 1642. As between the first and second, which did you consider the best carbon, eliminating the question of liability to fracture from consideration?

1477 A. In some forms of our lamps we preferred the first and in some forms the second, simply for mechanical reasons. As a whole we preferred for the incandescent conductor of the lamp, as I have stated very fully heretofore, the conductor of fibrous carbon, which is the first.

X Q. 1643. I call your attention to the following question and answer of yourself in the interference proceeding:

"Q. Then as I understand you, there was no objections to the burner made of the paper carbon?

"A. Yes; there were objection at first; it was too fragile; it was not good enough conductor for the electro-dynamo machine which we used. The burner had too high resistance. When carbonized with a current, it was liable to crack and to break from contraction. But it had advantages at the same time which we were trying to secure and were working for. When made of pure cellulose, it was a pure carbon, which we were trying in every way to obtain. That is why we kept working at it and finally succeeded in overcoming all its objections."

From this testimony it would seem that you considered a paper carbon, pure and simple, as being too fragile and as having a too high resistance but that you considered it a pure carbon and so kept working with it until you had finally overcome all its objections. Is such the fact, and if so, how were the objections overcome by the treatment to which you have been referring?

Objected to as incompetent; it being a mere fragment of the deposition referred to and as immaterial, having no bearing upon the issue in controversy.

A. Your statement is not a fair statement or conclusion from the testimony you have quoted; you generalized from a particular statement and ask me to adopt your generalization in answering. I do not desire to change the answer you have quoted, and if your question relates solely to the particulars of that answer I will reply,
but I cannot adopt your generalization; I speak in that an-
1478 swer of the difficulties of using the paper carbon with us at
first only; if you ask how we overcame those difficulties, I can tell you some of the things which we did, perhaps not all.

X Q. 1644. In your first use of paper did you find that it was too fragile?

A. As the conductors were made by us, at first, yes.

X Q. 1645. How did you obviate that defect, if at all?

A. In part by cutting the conductors to shape and size before carbonization; in part, by better carbonization of the conductors so cut to shape and size and in part by modifying our lamps; in part we rendered the conductors sometimes and usually, but not always, less fragile by an electrical treatment.

X Q. 1546. Did the electrical treatment make the conductors less fragile?

A. Yes, harder and denser.

X Q. 1647. I quote from the testimony of Wm. E. Sawyer in the interference.

"Q. 15. Referring now to the paper carbons, some of which are represented in the sketch Sawyer Exhibit No. 6, state whether or not you put them in a sealed lamp and tested their practicability.

"A. Yes, sir, we did.

"Q. 16. Did you try any of the carbons illustrated by the drawing Sawyer Exhibit No. 6, and if so, which of them?

"A. The carbons shown in Figs. 1, 2 and 3 and the half circle, were positively used; were sealed up and run; the great trouble with them was when we raised the temperature till we could get a bright light they would break; for this reason I preferred the harder carbons; we finally made them hard enough by treating them in hydrocarbon gas by the Sawyer-Man process."

It is true that in the early use of carbons made from paper
1479 "the great trouble with them was when we (you) raised the
temperature till we (you) could get a bright light they would
break?"

A. In the early use of the paper carbons I remember trouble with their breaking; we attempted to run them up, I think now, to too high incandescence, and our lamps and holders were not all adapted to their *use*.

X Q. 1648. Sawyer in this testimony says: "For this reason I preferred the harder carbons; we finally made them hard enough by treating them in hydrocarbon gas by the Sawyer-Man process." Is that your recollection of the fact?

A. My recollection is that we did treat them with this object in view, and that those so treated were successful in use, but it is also my recollection that some, not treated, were also successful in use; I understand Mr. Sawyer to be speaking in a general way of the subject-matter there, and in such a way, his testimony is correct.

X Q. 1649. Did you in your early experiments find that the paper carbon, pure and simple, was not a good enough conductor for your dynamo machine; that such a burner had too high a resistance?

A. Yes; we found that the paper carbons we made in our early experiments were of too high a resistance for the current of the dynamo we were using, and we had to get increased electro-motive force to pass sufficient current through them to heat them up to incandescence.

X Q. 1650. You remember that fact distinctly, do you?

A. Yes, sir.

X Q. 1651. Which did you do, increase your electro-motive force or decrease the resistance of your conductors?

A. We did both.

X Q. 1652. How did you increase your electro-motive force by get-ing another machine?

A. We increased our electro-motive force, in some instances,
1480 by rapidly making and breaking connection in a short circuit
shunt between the poles of the machine, and in some instances we charged the field magnet of one machine by a current from another; we varied the velocity of the armature, getting higher velocity than we could usually attain by waiting until after the other machinery in the building where we were was stopped, and then using the increased velocity of the pulleys in the building with which the machine was connected; we used sometimes, I think, with these paper carbons at first the current from the arc-lighting machine of Arnoux and Hochausen in the basement.

X Q. 1653. Would the expedients you mentioned in your last answer serve for the conduct of any experiments that would give you any valuable information in regard to the conductors?

A. Yes.

X Q. 1654. Could you run a conductor to incandescence for any length of time by the use of these expedients?

A. Yes, by some of them.

X Q. 1655. By which?

A. By the coupling up of two or more machines—by increased velocity of the armature, or by the use of the arc-lighting machine having a higher electro-motive force than the others.

X Q. 1656. How much could you increase the electro-motive force by coupling up the machine or increasing the velocity of the armature?

A. I don't know—enough, so that we passed the current through the paper carbons and heated them up.

X Q. 1657. Did you continue to resort to these expedients, and thus continue these experiments on these high-resistance carbons, or did you abandon experiments on them and work with carbons suited to your machine?

A. We reduced their resistance by treatment, and by making them larger, until they would serve as conductors with the currents we had available, but we frequently had not sufficient current, and had to wait until the other machinery was stopped before we could run our lamps. 1481

X Q. 1658. Do you mean to be understood that you gave up the use of carbons of such resistance as to be beyond the normal capacity of your machines?

A. Of course we used carbons mainly that were suited to the capacity of our machines; I do not think that we gave up experiments in making carbons while we were there at 43 Centre street.

X Q. 1659. What you did do, then, as I understand, was to bring the resistance of the carbon down to the capacity of the machine?

A. Yes; that, and to arrange and run the machines to the carbons, chiefly reducing the resistance of the carbons to the normal capacity of the machines.

X Q. 1660. If you had designed conducting experiments to any extent on carbons whose resistance was beyond the normal capacity of the machines, the proper thing to have done would have been to have got a machine of greater electro-motive force?

A. It would be the proper thing to do to get a machine of greater electro-motive force for the conduct of experiments on carbons of very high resistance, but it would not indicate that we did not design to conduct such experiments that we failed to get such a machine; it will be borne in mind that we were at work upon other things than the carbon conductors of our lamps.

X Q. 1661. You have said that in your early experiments you found the resistance of the paper-carbon conductors too high, and reduced the resistance. How did you reduce the resistance?

A. We made them larger and shorter, and we treated them

1482 by the electrical treatment and by soaking them in sugar, etc., and recarbonizing them or soaking them, as I have explained.

X Q. 1662. Which of these methods did you generally or finally adopt?

A. We almost always treated them by the electrical process, but not always by any process, and I think all the processes were practiced more or less up to March, 1879, not, however, after we left 43 Centre street, ordinarily with a view to reduce the resistance, but to improve the conductor.

X Q. 1663. In view of the fact that you found your first carbons of too high resistance, and reduced the resistance as you have stated, can you tell me the dimensions of the carbons whose resistance were too high, and what size you had to make them, and to what extent you had to treat them to bring them within the normal capacity of your machine? I am referring to the time you were at 43 Centre street.

Objected to as mere repetition, as this subject-matter has been all gone over in this examination once, if not twice.

A. Our carbons were usually made of a resistance equal to a well-made deposit carbon, of deposit carbon pure and simple, or conductor, of a length of from half an inch to three-quarters of an inch, and a twentieth of an inch in diameter; some of them that we made were of a great many times this resistance—how many I can't say—and some of them were many times less this resistance, and we prepared the fibrous carbons giving to them all these kinds of resistance, but we usually used them of about the same resistance I have stated of the deposit carbon of the length and size stated.

X Q. 1664. Which did you find in practice the more durable carbon—the fibrous carbon treated by your electrical process or the carbon not treated?

1483 A. I think all the carbons were improved by the electrical treatment and rendered more durable, and I think they are to-day so improved by such treatment.

X Q. 1665. It appears, by the record in the Sawyer-Man-Edison interference, that Mr. Broadnax asked Mr. Sawyer the following question, and received the following answer, referring to the use of paper carbon:

"Q. How long did they last in the lamp?

"A. Untreated by the Sawyer-Man process would last from one second to ten minutes, if run up to give a good bright light; if run at a low temperature, they would run anywhere from one hour to a hundred hours; it depends entirely upon the temperature."

Is it your recollection that while at 43 Centre street paper carbons, which had not been treated by the Sawyer-Man process, would last if run up to give a good bright light from one second to ten minutes?

A. It is my recollection that while at 43 Centre street, and indeed up to March, 1879, we usually ran our carbons up to very high incandescence—much higher than the incandescent lamps of to-day are run, so high that a single lamp would illuminate a large, dark room, with rough walls and ceilings, of about twenty by forty feet in size and about ten or eleven feet high, which was the character of our room at 43 Centre street, and I take it that that is what Mr. Sawyer means by a good bright light; if such interpretation were put upon his testimony I fully agree with him; I know that many of our paper carbons untreated were destroyed, as Mr. Sawyer states, but many others untreated run at low incandescence, giving a fair light, lasted the longer times, he states.

X Q 1666. Was this high incandescence at which you usually run them the degree of incandescence which you then considered proper or desirable?

A. Yes; I think we had some idea of competing with arc lamps.

1484 X Q. 1667. Is it the fact then that the life of these untreated paper carbons when run to the degree of incandescence which you then thought proper or desirable was from one second to ten minutes?

A. Yes, usually.

X Q. 1668. On cross-examination the following question was asked and the following answer was made by Mr. Sawyer:

"X Q. 49. Referring now to your 17 answer, could a lamp as described there which would burn from one second to ten minutes be used in competition with gas or other commercial lights?

"A. It could not; and at that — the invention was not so perfected in all respects, including the inclosing globe and mechanism as to make the lamp suitable for any practical purpose; by mechanism I mean the general construction of the lamp, method of sealing conductors, &c.; 'that is, all the attachments of the lamp and the general mechanical construction of the lamp.'"

Do you agree in the opinion of Mr. Sawyer and is the statement of facts made in the answer true according to your recollection?

A. I would agree to the statement until the latter part of the time we were at 43 Centre street; my opinion is that some of the lamps we had when we left 43 Centre street, were supplied with fibrous carbon and were good commercial lamps considering the then state of the art of incandescent electric lighting.

X Q. 1669. The following question was asked and the following answer made by Mr. Sawyer in the interference referred to:

"X Q. 18. State as near as you can recollect how long the best of the paper carbons you made at 43 Centre street would last in the lamp when raised to a temperature high enough to give a good bright light, after having been treated by the Sawyer-Man process?

1485 "A. Run at a power of about 25 candles they would last from five to 100 hours; once in awhile we would get a lamp so perfect in every respect that it would seem to undergo no changafter a long use, but generally they would fracture in 5 to 20 hours run at that temperature; the difference in the duration of the burners was due to both imperfection in the lamp and in the carbon; where the fracture alone occurs it must be due either to imperfection in the carbon or the effect of unequal expansions; when consumption occurs it is due to the imperfect charging of the lamp."

Is it your recollection that the treated paper carbons when run at about twenty-five candles, would generally last from five to twenty hours?

A. I can only say that my present recollection of it is not sufficient for me to state, but I have no reason to criticize Mr. Sawyer's statements taken as a whole, and think it is probably as nearly accurate as he could give it.

X Q. 1670. On cross-examination in the interference referred to, the following question was asked of Mr. Sawyer and answer given:

"X Q. 50. Referring now to your 18 answer, could a lamp as described there which would burn from five to one hundred hours be used in competition with gas or other commercial lights?

"A. I think not."

Is such your opinion?

A. No; there are situations and places where such a lamp would drive out the use of gas in my opinion, and it would depend upon the facilities at hand or available for restoring such lamps, as is the case with the arc light, whether it could compete with gas or not, commercially; in some places it could, in others it could not so compete, in my opinion.

Adjourned till Thursday, the 8th inst., at 10½ a. m.

1486 THURSDAY, *Dec.* 8, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1671. Referring to the specimens of excelsior, manilla and broom-corn offered in evidence, did you ever make a lamp in which the carbon was made of manilla fibre?

A. I do not know; we tried such carbons in our lamps, but I don't know whether we made a successful lamp with it or not.

X Q. 1672. Why do you not know?

A. Simply because I do not recollect.

X Q. 1673. Do you recollect of running any of such carbons to incandescence?

A. Yes, I recollect of carbonizing them and trying it.

X Q. 1674. Did you get a current through?

A. Yes, I think through the single fibres of short lengths; I know we did through the twisted fibres or strings of the same; I mean the manilla.

X Q. 1675. How short were these single fibres?

A. I don't think more than a quarter of an inch long between the holders; they may have been longer, but I judge not.

X Q. 1676. How did you support these single fibres in the holders?

A. The ends were placed in clamps at the tops of the holders.

X Q. 1677. What sort of an atmosphere did you use in the lamps where these were tried?

A. Hydrocarbon gas, hydrogen and nitrogen were the gases that we were using and all our trials were made in one or more of these gases or in a vacua of those gases.

1487 X Q. 1678. How long did you get any one of these single manilla fibres to remain incandescent?

A. I don't recollect.

X Q. 1679. Can you give no idea?

A. No, I cannot.

X Q. 1680. Did you have a machine which would, when worked to its normal capacity, render them incandescent?

A. Of short lengths.

X Q. 1681. Were they delicate carbons to handle and place in the lamps?

A. Yes.

X Q. 1682. How did they compare in your estimation with the larger and harder carbons?

A. I do not recollect; the carbon of manilla fibre was a hard carbon comparatively.

X Q. 1683. Did you ever make a lamp in which the conductor was made of manilla fibre?

A. I do not recollect that we made any lamps in which the carbon was of single manilla fibre, though we tried it by way of experiment; we did make some in which the carbon was of twisted manilla fibre in the form of loops; they did not last any better, if as well, as the paper and wood carbons; they wore more difficult to make and use and we did not continue to make them, preferring the others.

X Q. 1684. Is what you have said of manilla equally true of jute?

A. It is, except that we did not like the jute as well as the manilla.

X Q. 1685. What were the endogenous woods you carbonized?

A. I don't know, and I don't know whether I knew at the time; we got them to carbonize by reason of our thinking that their interlacing fibres might be an advantage?

X Q. 1686. What endogenous woods have interlacing fibres?

1488 A. I don't know; I think the palms and the other larger growths of endogenous woods.

X Q. 1687. Did you ever make a lamp in which the carbon was made of *odengneous* wood?

A. Yes, we simply did it, though, by way of experiment.

X Q. 1688. Did you ever*y* try excelsior in a lamp?

A. Yes.

X Q. 1689. With what success?

A. The excelsior carbons were mostly too fine and high resistance for our current, and we did not make much use of them; we carbonized them and tried them in the arch form, but had to make the arches too flat of it to satisfy us; its use was experimental.

X Q. 1690. Did you ever try the broom-corn in a lamp?

A. Yes; either while at 43 Centre street or at the corner of Walker and Elm streets, I can't recollect which.

X Q. 1691. With what success?

A. We bent and carbonized broom-corn in the form of loops, for conductors, but I do not think we saw any advantage in it, and I remember it only as a thing we tried experimentally.

X Q. 1692. The patent in suit mentions the use of a vacuum, and you have, throughout your deposition, mentioned the use of a vacuum in your lamps, or the use of an attenuated atmosphere of some non-combustion supporting gas; what means had you, at 43 Centre street, for supporting a vacuum?

A. We had an air pump, worked by hand, and we also used an exhausting apparatus with mercury.

X Q. 1693. Where did you get the hand pump?

A. We borrowed it, or Sawyer did; I don't recollect where, if I knew, nor from whom.

X Q. 1694. About how long after you had been to Centre street was it borrowed?

1489 A. I cannot recollect, but I should judge a week or so, or two weeks; it may have been sooner.

X Q. 1695. Did you have the continuous use of this pump while you were at Centre street?

A. I don't know; we had the use of a pump, this or others, while there; I do not recollect about it, because I did not personally get or borrow the pumps or pump.

X Q. 1696. You speak of "pumps," were more than one borrowed?

A. I don't know whether the same pump remained there all the time after we borrowed it, or whether it was borrowed more than once, or whether other pumps were borrowed.

X Q. 1697. Do you remember whether you had the continuous use of a hand pump?

A. No; I only remember using it when we wanted to.

X Q. 1698. Do you remember whether you always had it there to use when you wanted to?

A. I do not remember whether we always had it there or not.

X Q. 1699. What was the exhausting apparatus used with mercury?

A. It was of the character of a Geissler pump, used by displacement of air by mercury.

X Q. 1700. Where did you get this apparatus?

A. We rigged it up ourselves.

X Q. 1701. By "ourselves" who do you mean?

A. Mr. Sawyer and I.

X Q. 1702. Where did you get the parts which you thus rigged up?

A. I forget; I think though that I got the reservoir either from Haggerty Brothers, in Platt street, or from the glass house in Brook-

lyn; it was the one lying south of the South Seventh-street ferry; a continuation of the street running north and south by that
1490 ferry and several blocks south of the ferry, or to the right hand as you cross the ferry from New York.

X Q. 1703. Where did you get the glass tubing and stop-cocks?

A. I don't know; we bought such at a variety of places, among others from Frasse, in Chatham and Fulton streets, New York; from Hahn, in North William street; from the glass factory I have mentioned, and perhaps at other places, and I had some at my house which I brought over and used.

X Q. 1704. Did you have any glass-blower assist you in putting the apparatus up?

A. No; we put it up ourselves.

X Q. 1705. Did you individually possess sufficient skill to put the apparatus up?

A. Yes; it required no great skill.

X Q. 1706. Please describe in detail this apparatus, and state when it was put up and where in the room?

A. The apparatus I cannot describe in its minute details; generally it was a glass reservoir with three outlets, one to the open air on top with a stop-cock in it, two at or near the bottom of the reservoir with stop-cocks, one connecting to the lamp chamber through glass and rubber tubing, the other to a bottle having two outlets, one at the top and the other near the bottom; the last bottle was larger than the reservoir I first spoke of; it was used in different places in the room; the apparatus was put up soon after the purchase of the mercury shown by ——; that purchase as appears by my check book was paid for to Charles P. Pfizer & Co., April 6, 1878; the stop-cocks were of glass and bought of Mr. Hahn in North William street; the usual place of working this apparatus was on a bench in a little room partitioned off from the main room by a canvas partition.

X Q. 1707. Did you use this apparatus to any extent for obtaining a vacuum?

A. Yes; we used it frequently, not always.

1491 X Q. 1708. Could you get a vacuum with it?

A. Yes; very good.

X Q. 1709. Better than with the hand pump?

A. Yes; much better.

X Q. 1710. Were you troubled with mercury vapor?

A. I don't know; I don't recollect.

X Q. 1711. You remember no trouble of that kind?

A. I don't remember observing any.

X Q. 1712. Did you have any trouble with it?

A. I don't recollect any trouble with it except in keeping the joints tight and in bursting a rubber tube connecting between the two reservoirs and bottle.

X Q. 1713. How did you keep the joints tight?

A. We covered them with rubber tubing and tied them over with strings.

X Q. 1714. Did Sawyer ever complain of this apparatus as creating a mercury vapor?

A. I don't remember; we might have had trouble of that kind and Sawyer may have complained of it, but I do not recollect that he did.

X Q. 1715. Do you remember taking any precautions to avoid the creation of a mercury vapor?

A. I do not.

X Q. 1716. Had you ever tried such an exhausting apparatus before?

A. Yes.

X Q. 1717. Where?

A. I don't know.

X Q. 1718. Do you know whether Sawyer ever had?

A. I don't know, I only know it was not new to me and I don't think it was to Sawyer.

X Q. 1719. Is it then the fact that you put this apparatus up and that it had worked successfully from the start?

A. Yes, we put it up, had some trouble with the bursting of tubes or rubber tubing and it worked well enough for our purposes.

1492 X Q. 1720. Which did you prefer, a vacuum or an inert gas at atmospheric pressure for your lamps?

A. We were most successful with an atmosphere of inert gas at atmospheric pressure, as compared with the vacua that we obtained without the gas, but I think we preferred a vacuum or partial vacuum of inert gas to either.

X Q. 1721. Don't you know which you preferred?

A. I do not remember exercising ourselves in regard to it; I think clearly that we preferred the inert gas at atmospheric pressure to an atmospheric vacuum such as we obtained. By "atmospheric" I mean such a vacuum as contained no inert gas or remnants thereof, but only a remnant of atmospheric air.

X Q. 1722. As between an inert atmosphere at atmospheric pressure or a vacuum where the residual atmosphere was an inert gas, which did you prefer?

A. We very rarely had, if ever, an atmosphere in our lamps when they were finally closed up at atmospheric pressure, but somewhat less than that. I do not remember that while we were at 43 Centre street we had formed any decided preference as to the degree of pressure or attenuation of the atmosphere of our lamps; it was only, as I think now, after we went to the corner of Walker and Elm streets that we began to think that it was a possible advantage to reduce the amount of gas in the lamps. Still, I may be mistaken in this, but I think not.

X Q. 1723. Did you ever form a preference for either?

A. Yes, I think while at the corner of Walker and Elm streets, in the fall of 1878; at all events we practiced extensively the exhaustion of the air of our lamps.

X Q. 1724. You say you "think;" do you mean that you are in doubt as to whether you did?

A. No, I don't think I am in doubt in regard to it; I think we preferred clearly and distinctly the exhausted chamber, but there were other questions connected with the matter that complicate the matter in my mind.

1493 X Q. 1725. I do not understand whether you are clear as to whether you preferred one over the other or are merely conjecturing in regard to it. Did you have a distinct preference at any time?

A. Yes; we did have a theoretically distinct preference in regard to the matter is what I mean to say.

X Q. 1726. What do you mean by "theoretically"?

A. We recognized the fact that any atmosphere with which we could fill the lamp could not be a perfectly inert atmosphere. We also recognized the fact that a perfect vacuum would be. The complication- of which I have spoken have reference to our practical difficulties in getting even an approximation to such a vacuum and then sealing up our lamps and having the vacuum preserved in them.

X Q. 1727. You say you recognized these difficulties. Now, as a practical question, did you ever reach any preference?

A. Yes.

X Q. 1728. Which was it for?

A. It was for an attenuated atmosphere in an inert gas.

X Q. 1729. Attenuated to what extent?

A. We tried all extents from slightly below atmospheric pressure, perhaps a third of the pressure removed, up to the highest that we could get; we had difficulty in preserving while sealing up the higher attenuation, and we adopted ordinarily in practice therefore a less attenuation than the highest that we could get, as an ordinary thing.

X Q. 1730. Can you give me any idea as to the degree of attenuation which you preferred?

A. No, I don't recollect. I don't think we could know what the degree of attenuation was, but only the pressure of the atmosphere in the lamp which was always hot when sealing it up; my idea would be now that we ordinarily reduced the pressure perhaps a half, perhaps more, perhaps not so much, perhaps only a

1494 third, from a third to two-thirds, and it was still further reduced when the lamp was cooled off; this was only in lamps in which we were endeavoring to have a vacuum or partial vacuum; in much the greater number of our lamps we used the pumps only as a method of exhausting the air and for filling the lamps with the inert gases; so that they were more nearly at atmospheric pressure than the others.

Adjourned till Friday, the 9th inst., at 10½ a. m.

FRIDAY, *December* 9, 1887.

Met. Present, counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1731. Aside from the fact that no inert atmosphere is absolutely inert toward carbon when incandescent, were you of the opinion that it was disadvantageous in any other respect?

A. There are certain degrees of vacua in which the current seems to be transmitted, whether conducted I cannot say, in the manner of the Geissler tube, and certain degrees of exhaustion in which the electric arc seems to be more readily established than in a plenum at ordinary atmospheric pressure or in a high vacuum; a higher exhaustion and a less exhaustion do not have the same results in these particulars; again, the higher the exhaustion the less the conduction of heat by the atmosphere of the lamp; again, the higher the exhaustion the less the wearing away of the conductor by the impingement of the atoms of the air or atmosphere against the conductors, sometimes called the bombardment of atoms, referred to in the kinetic theory of gases.

X Q. 1732. Did you recognize these facts at the time of your experiments?

1495 A. We did.

X Q. 1733. What effect had the conduction of heat on the candle power of the lamp?

A. Of course to the extent that heat was conducted away from the incandescent portion, the candle power of the lamp was diminished; I do not mean by this that the loss in candle power was an exact fixed ratio to the loss of heat from the conductors; the ratio would increase as the loss of heat increased.

X Q. 1734. Would *now* current then be required to bring the lamp up to incandescence?

A. It would.

X Q. 1735. You recognized that then, a high vacuum, if it could be first obtained and when maintained, would be preferable to an inert atmosphere?

A. Yes, unless the vacuum was one of inert atmosphere; that is preferable to any other atmosphere.

X Q. 1736. Why then did you not employ a high vacuum of either atmospheric air or an inert gas?

A. We did so employ it, but it was not our ordinary method or practice.

X Q. 1737. Why did you not adopt it as your ordinary method or practice if you knew it to be superior?

A. Because of the difficulty of securing such a vacuum, the long time consumed with our apparatus in getting it and the difficulty of maintaining it when obtained and because we were hurrying to get lamps to exhibit and put in use, and because that our lamps with a very moderate exhaustion and little below the normal pressure of the atmosphere seemed to us good enough for practical use.

X Q. 1738. The patent in suit in its 4th claim, as one of the elements of the combination thereof, speaks of "an illuminating chamber made wholly of glass, hermetically sealed." The specification of the patent speaks of a "lamp chamber" composed
1496 wholly of glass as described in the patent 205,144; did you

and do you consider the lamp chamber of patent 205,144 as made wholly of glass?

A. Yes.

X Q. 1739. Referring to your answer to questions 50, 51, 52, 53, 54, 55, 56, 57 and 58 of your direct examination do you know of your own knowledge that lamps were made as there described?

A. Yes; I saw them at the place, 94 Walker street.

X Q. 1740. Did you see them made?

A. No.

X Q. 1741. You say but a few were made, about how many?

A. I don't know; three, four or five of them came under my observation at the shop in Walker street. I had not known of their being made until I saw them in the shop. I then asked Mr. Sawyer in regard to them, or first his father and then him; his father's time was being taken up with these lamps when he had other work assigned to him; he told me that his son had got them made and directed him to do the work; I asked Mr. Sawyer then in regard to them and he told me he had got them blown at the glass-blower's right opposite our shop, or nearly opposite, in Walker street, where we had had some small amount of glass-blowing done; the lamps were put up by Mr. Sawyer and he called my attention to them again several times; I don't think I ever saw but one of them at a time lighted up, whether the same lamp or different ones I do not recollect, but I believe different ones.

Defendant's counsel objects to what Sawyer stated to witness as incompetent.

X Q. 1742. Then you were not consulted and did not know as to the making of these lamps?

A. No, not at first; Mr. Sawyer was at the time in charge of the shop and gave directions for the work to be done, usually consulting with me in regard to it beforehand, but in this case he did not.

1497 X Q. 1743. Then you do not know of your own knowledge how these lamps were made except as you inferred from the completed structure or as Sawyer told you?

A. The completed structure showed how they were made and Sawyer also told me.

X Q. 1744. Is your recollection of these lamps clear?

A. Yes, *a* lamps all used together and not in separate parts.

X Q. 1745. What kind of carbon did they have?

A. The same carbons as our other lamps; I can't recollect whether circular or straight; I think circular.

X Q. 1746. Did they have hollow conductors?

A. Yes, one hollow conductor, not two; I think one of the lamps had a glass tube instead of a metal one, and the conductor in that lamp in the tube was solid, making both conductors solid.

X Q. 1747. Is your recollection clear as to there being such a lamp?

A. Yes, my recollection is clear in regard to it.

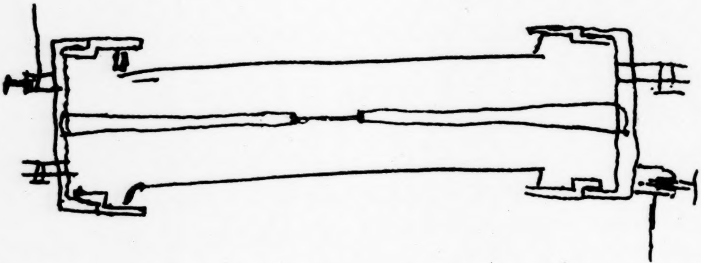
X Q. 1748. Please illustrate by a sketch each of these lamps.

A. Figure 2 of patent 317,676 will show the general appearance

BROADNAX & BULL,
COUNSELLORS AT LAW,
120 Broadway,
NEW YORK

Especial attention given to the Law of Patents.

AMOS BROADNAX,
J. EDGAR BULL.



Defendant's exhibit
Chan Slatch no 2
Oct 11 1887

No. 286.
C. E. Light Co.
v.
McK. Light Co.
p. 1498

of one lamp when set up; Fig. 5, of the same patent, shows the construction of the bottom of the lamp, the only difference being that the flange *x* of the globe and the base piece *y* were fused together after the interior works of the lamp were set up; the base, *y*, was thinner than as represented in figure 5 of the patent referred to.

Witness makes a sketch.

(Witness continues:) I have made a drawing, illustrative of a base of one of the lamps that I saw; there were other constructions which I saw, but I cannot remember them with sufficent accuracy to make drawings of them; in one, I know there were two glass tubes fused in the base into which conductors were fused.

(Here follows diagram marked p. 1498.)

1499 Drawing offered in evidence, and the same is marked "Defendant's Exhibit Man Drawing Dec. 9th, 1887."

X Q. 1749. Referring to the drawing, did the metal conductor C pass out through a hole in the tube A?

A. Yes, through a hole in which it was fused.

X Q. 1750. Did the glass tube A have an open outlet into the interior of the lamp?

A. It did.

X Q. 1751. Was the conductor C sufficiently loose in the tube A to admit of exhausting or charging the lamp by means of this tube?

A. Yes.

X Q. 1752. What was the material and size of the metal conductor B?

A. I think it was a brass wire; both the conductors B and C at first, I think, were brass wires.

X Q. 1753. Why did you say "at first"?

A. Because they afterwards changed it, using an iron wire.

X Q. 1754. In other respects the lamp conformed to the general style, shown in the patent in suit?

A. Yes; one, however, was different, but I cannot recollect it with sufficient accuracy to describe it.

X Q. 1755. The order in which these parts were made or put together you do not know of your own knowledge?

A. Only as I could judge what it was from what I knew of glassblowing.

X Q. 1756. Have you now testified in answer to my questions, as to all that you remember on this subject?

A. All that occurs to me now.

X Q. 1757. If there was any invention in the doing of what you have just described it was the sole invention of Sawyer, was it not?

A. Neither Mr. Sawyer nor I thought there was any invention in it; if there was, I did not claim any part of it; if there was any invention, it was his alone, but it belonged to the Electro Dynamic Light Co., under his agreement with that company. 1500

X Q. 1758. Was the character of construction followed up in any way?

A. No more than those few lamps, so far as I know.

X Q. 1759. You say in your 49th answer that Exhibit No. 29 was blown directly from the pot in your presence; was it blown in a mould?

A. No.

X Q. 1760. Was any commercial use made of the lamps you have described previous to my last question, I mean those having the glass bottom plate fused unto the globe?

A. The only use that was made of them was to set them up in our shops and run them for lighting up the place and show them to people who came in, so far as I know.

X Q. 1761. Your usual method was to clamp the parts and not fuse them?

A. It was.

X Q. 1762. You preferred the clamping?

A. I think we did; we preferred to fit them together so that we could take them apart and renew the carbons, and recharge them or exhaust them.

Adjourned till Monday, 12th inst., at 10½ a. m.

1501 MONDAY, *December* 12, 1887.

Met pursuant to adjournment.

Present, counsel as before, and the cross-examination of Mr. MAX was continued as follows:

X Q. 1763. In answer to your 87th question, referring to the use of the soapstone disc, —:

"We subsequently ascertained that it was not necessary, and ultimately left it out."

When, in point of time, did you ascertain that it was not necessary?

A. We came to the conclusion while we were at 94 Walker street, in the fall of 1878, that the disc of conducting or insulated material, to which you refer, for the purpose for which it was first introduced, viz., to prevent the radiation of heat, was not necessary, but for the purposes secondly introduced, the serving as a base or support for the conductors or holders and the incandescent conductor, that it was useful. So long as Mr. Sawyer and I were together, until March or April, 1879, we continued its use for this latter purpose, modifying it in form and shape and materials used.

X Q. 1764. If you considered the disc unnecessary for preventing heat in the fall of 1878, why did you, in the patent applied for on November 5, describe its use for this purpose and claim it?

A. I think our conclusion that the disc was not a necessity for preventing radiation had not been reached at that time, and possibly not till the winter of 1879. Whether it was or not, I do not think, so long as Mr. Sawyer and I worked together, that we were convinced that the disc referred to might not be of some use in preventing the radiation of heat to the base of the lamp.

1502 X Q. 1765. I understand the fact to be that you and Sawyer always retained it, as a part of the construction of your lamps, irrespective of the purpose which it served.

A. We did, I think, so long as we worked together, up to and into March, 1879, but not of a size to fill the globe of the lamp and prevent radiation, but only as a base for setting up the holders and incandescent conductor.

X Q. 1766. In your 87th answer, referring to this disc, you say that ultimately it was left out; what do you mean by that statement?

A. I mean that the Eastern Electric Manufacturing Co. and the Consolidated Electric Light Co. left it out as a feature of the lamp, to prevent radiation, and its only remnant in the lamps of the latter company consists in the glass base projected inward into the lamp upon which the holders and incandescent conductors are set up, and which glass base is fused to the walls of the lamp chamber. It appears in Complainant's Exhibit No. 21, in this remnant form.

X Q. 1767. Was not the lamp that you considered you had perfected, when you left Centre street, and the lamp which you designed at that time to introduce commercially, a lamp of large carbon and lower resistance?

A. Yes; I think so.

X Q. 1768. With the exception of such experimental lamps as you made after that period, were not your efforts directed mainly to the improvement of that type of lamp?

A. I think we gave more attention to the making of a lamp of moderate resistance than to attempt to realize the advantages of a lamp of high resistance, for the reason which I have heretofore stated.

X Q. 1769. Is it not true that, so far as there was any difference between the smaller and larger carbons, you preferred, for the reasons that you have stated, the larger carbons?

A. It is hardly fair to express it in that way. It was not 1503 a question of larger carbons or smaller carbons—a question of high or low resistance, but a question of what we could do with the means at our command; and we made mostly the larger carbons, with low resistance, because we could run them—a lot of them together—while we could only run one, or at most two, of the finer carbons with the current at our command. It was a question, therefore, of making a good lamp, and the question of high resistance or low resistance, as a matter of preference in my mind, I do not think existed. We considered, I believe, that having made good lamps of any suitable resistance for giving proper light, we could make lamps of higher or lower resistance than those we had made, within the limits of practicability and suitable to currents, available for use, of higher or less electro-motive force.

X Q. 1770. But the fact is, is it not, that the ordinary lamp you built was one that had a comparatively large carbon and low resistance?

A. Yes, in comparison with most of the incandescent electric lamps of the present day. Some of the electric lamps of to-day have carbons of larger cross-section than those we ordinarily used, but I think they are longer and of higher resistance than our carbons usually were.

X Q. 1771. While you were at 43 Centre street, how long, of your own knowledge, did a carbon remain at continuous incandescence. I mean to inquire as to what you yourself know, independent of any statements made to you by others, in regard to the incandescence of the carbon?

A. I saw the same carbons, in the same lamps, without intermission run for hours at a time, three, four or five hours or longer, all an evening and all an afternoon, at several different times.

X Q. 1772. It was not your custom to be at Centre street as long as three or four or five hours at a time, was it?

A. No, sir.

X Q. 1773. These, then, were special occasions?

1504 A. Yes, sir.

X Q. 1774. The engine in the building on which you were dependent did not run at night, did it, except by special order?

A. No, sir.

X Q. 1775. On the evenings to which you referred, did you make special arrangements for the running of the engine?

A. We did.

X Q. 1776. Who made these arrangements, and with whom were they made?

A. The engineer. I forget whether by myself or by Mr. Sawyer at any particular time. Sometimes one of us and sometimes the other; usually Mr. Sawyer.

X Q. 1777. What was the occasion of the running at night?

A. To exhibit our lamps and to run them continuously a longer time than could be done while the engine was usually running.

X Q. 1778. Who were present at these exhibitions at night to which you refer?

A. I do not remember. A large number of people at different times. I remember Mr. Lawrence Myers being there; Mr. William Hays; Mr. Jacob Hays; Mr. Classon; Mr. Hugh McCulloch, I don't know whether at night or in the daytime; other gentlemen invited there by Mr. Sawyer, whose names I do not recollect, if I knew them; other gentlemen invited there by myself, whose names I cannot recall.

X Q. 1779. Can you mention any gentlemen now present who you know were present at one or all of these exhibitions at night?

A. I think all of the gentlemen I have mentioned, with the possible exception of Mr. McCulloch, saw the lamps running at evening. I do not think any of them remained during all the time that
1505 the lamps were lighted up. Mr. William H. Church was also present, and saw them running at evening.

X Q. 1780. What I desire to know is, if you are certain, so certain that you do not think, but know, that some gentlemen now living that were present at any or all of these evening exhibitions. If there is any person or persons whom you know were so present, please mention their names.

A. I have given you the best of my recollection upon this subject. It is ten years, or nearly so, ago. I feel the greatest confidence, and think I know that all of the gentlemen that I have named, except possibly Mr. McCulloch, were present, and saw the lamps running at evening at 43 Centre street, but I do not claim to be infallible in my recollection. I only say that such is my recollection, and I think I know it.

X Q. 1781. Are you as confident that these gentlemen saw these lamps running at 43 Centre street as you are of any other fact concerning which you have testified?

A. No; some one or more of these gentlemen might have seen it in the daytime and not at evening, and I might be mistaken as to one or more of them, but I think not.

X Q. 1782. As I understand, these were exhibitions to show the lamps running?

A. Some of them were and some of them were not. Some of them were for trial of the lamps.

X Q. 1783. And about how many occasions did you run these lamps at night?

A. I cannot tell; perhaps a dozen times?

X Q. 1784. On each occasion you were dependent upon the power in the building, and had to depend on the engine in the building being run after hours?

A. Yes, but sometimes other people in the shops wanted
1506 to work at night, and the engineer would advise us that he
was going to run after hours and we could avail ourselves of the opportunity thus furnished.

X Q. 1785. What was the usual time that the power in the building shut down?

A. Six o'clock, I think; it was frequently after dark.

X Q. 1786. How late do you remember running at night?

A. I should think nine or ten o'clock, but not usually later than eight or from eight to nine.

X Q 1787. Now, these exhibitions that were made in the evening were exhibitions of completed and running lamps, as I understand?

A. Yes; so far as they were exhibitions.

X Q. 1788. About when did the first of these exhibitions take place?

A. Very soon after we went there to 43 Centre street, within a week or so; Mr. Sawyer invited a number of gentlemen to see the lamps lighted up after candle light, or they remained after candle light, I don't know which.

X Q. 1789. Do you remember any of the gentlemen who were present at that exhibition?

A. No, I do not.

X Q. 1790. Were you present?

A. During only a part of the time; I left before the rest.

X Q. 1791. The apparatus at this exhibition was, I suppose, comparatively crude?

A. Yes.

X Q. 1792. When was the first exhibition in the evening at 43 Centre street, in which you showed a well constructed and finished lamp?

A. I think in April, 1878.

X Q. 1793. What was the construction of the lamp exhibited?

A. I can't recollect, because we had various constructions.

1507 X Q. 1794. You mean you exhibited several different constructions of lamps?

A. Yes; mostly lamps with straight pencils or low, flat arches.

X Q. 1795. Were they of the same general construction, differing only in detail, or of radically different construction?

A. They were of the same general construction, except as to the holders and incandescent carbons and leading-in conductors; the shapes of the globes were different in differe-t lamps; some of them were straight and some of them had bulbs.

X Q. 1796. How many lamps did you run at a time at this first exhibition in April?

A. From two to four, probably; at different times we ran different numbers of lamps, sometimes only one and sometimes as many as eight.

X Q. 1797. Were these lamps shown at this first exhibition of the construction shown in patent 205,144?

A. I cannot distinguish any exhibition in my recollection in the month of April as the first; the lamps shown in our exhibitions were generally similar, but not like it, the respect that the part G shown in the drawing of that patent was usually omitted and a spring was substituted for the weight of the part F usually; again, many of the lamps which we exhibited had the carbons running crosswise between the holders, some of them rising in arches above the holders, instead of standing vertically or upright as shown in the drawing of this patent; there is a type shown in figure 8 of the drawings of this patent which is more nearly like the lamps we usually exhibited.

X Q. 1798. In these lamps that you exhibited, what were the incandescent conductors made of?

A. Referring generally to the lamps shown to different people at different times while we were at 43 Centre street, the incan-
1508 descent conductors were generally made of mineral carbon or deposit carbon, treated according to our electrical process; some, however, were of fibrous carbon, wood or paper, treated according to our electrical process.

X Q. 1799. To whom were the lamps containing fibrous or paper-carbon conductors treated as described, exhibited?

A. I do not know; they were simply shown with our other lamps; Mr. Church and old Mr. Sawyer and his son George were the only persons that I think at that time knew of the fibrous carbons being used; others may have known it, but I do not know that others did.

X Q. 1800. Were any lamps containing fibrous paper carbon untreated, exhibited while you were at 43 Centre street?

A. I do not know of any, and I do not know that they were not;

I think and am confident that Mr. Wm. H. Church saw them used and knew what they were, and also Mr. Wm. Sawyer and George Sawyer; of course Mr. Wm. E. Sawyer saw them.

X Q. 1801. Did these gentlemen that you think saw these lamps run, watch them running for any considerable period?

A. I don't know that they timed them; I think Mr. William H. Church watched their operation, but am not sure.

X Q. 1802. Was the construction of the lamp and the character of the carbon explained to them?

A. They saw the work going on and knew more or less of what we were doing. Of course in doing the work, more or less explanation, how much I cannot tell now, was necessarily given to Mr. Wm. Sawyer who worked on the lamps and in setting them up, and assisted generally. Mr. George Sawyer was employed principally as a messenger in sending in for different things and sometimes as an assistant merely, to his brother and father or to me.
How much explanation was given to him I do not know or
1509 recollect; he was a boy about 17 or 18 years old or less.
The construction of the lamps and the preparation of the carbons was, I think, explained to Mr. Church more or less by Mr. Sawyer or by me, mostly by Mr. Sawyer. I think he was pretty well advised as to what was going on.

X Q. 1803. On the occasion on which you saw the same carbon run at continual incandescence, for a period of three or four hours, were you present for the purpose of watching the continued burning of the carbon?

A. Sometimes, yes; when we were testing them. Sometimes no, when I was simply at the shop working or assisting or advising and consulting with Mr. Sawyer and the lamps were being run. Sometimes no, when I had invited people to see the lamps and simply went there and remained because they were there.

X Q. 1804. While at 43 Centre street, what is the longest period that you were told of a lamp being run at continued incandescence?

A. All day, from early morning until evening.

X Q. 1805. As to whether such was the fact depended upon the truth of the statements of the Sawyers?

A. In part yes; but in part confirmed by my own observation in seeing the lamps started or running, and afterward returning and finding them so, at midday and at evening.

X Q. 1806. But whether they had been running in your absence you do not know?

A. No, not further than I was told by the Sawyers, and I think Church.

X Q. 1807. How many hours of actual incandescence do you, of your own knowledge, know of any one carbon continually burning at 43 Centre street?

A. I cannot give the number of hours. We did not keep track of them. I saw the same lamps with the same carbons in them run
day after day at high incandescence, I should judge from 25
1510 to 50 candle pow*d*er, or higher sometimes, from some time

in April until we left 43 Centre street, the last of May or first of June. They were good then and the carbons seemed not to be affected by their use.

X Q. 1808. How do you know that the carbons had not been changed in your absence?

A. Because of the manner of setting up the lamps, and the appearance of the carbons themselves, and of the lamps. If they had been changed I should have observed it.

X Q. 1809. You had no reason to suspect that anything of the kind had been done or would be done, had you?

A. No, I knew of the carbons being changed in lamps very frequently, and observed the changes that were made, and observed those that were not changed, and was closely watching the lamps and the effect of their use upon the carbons.

X Q. 1811. You had no reason to suspect, at the time, that the Sawyers had or would deceive you, in regard to the life of these carbons, or to suspect that the carbons had been changed in lamps, which you were led to suppose had not been touched?

A. No.

X Q. 1812. You were not looking for deception on their part?

A. No, but I was looking to see that I was not deceiving myself. I do not remember ever asking them in regard to the changing of the carbon, for I observed the changes myself, and I was observing the carbons in the lamps, and the lamps, and how they were affected by use; watching them continually while I was there and they were running, or examining them if they were not running.

X Q. 1813. Your habit was to run these lamps until they gave out?

A. Yes, until the carbon gave out, or something happened
1511 to the lamps or until seeing, as we thought, a change for im-
provement in the lamp, we took it down, made the supposed
improvement and set it up again, sometimes with the same carbon,
sometimes with a different one.

X Q. 1814. Did you try running different carbons under the same conditions, to ascertain their respective life?

A. Yes, as nearly as we could.

X Q. 1815. I understand that the conclusion of your experiments in March, 1879, or rather prior to that time, while you were still at 94 Walker street, the Electro-Dynamic Light Co., considered your lamps so far perfected, as to order several hundred to be made. Is that the fact, and that a great many lamps were made in conformity to such order?

A. Yes.

X Q. 1816. About how many lamps were made in conformity to that order?

A. I do not know that I ever knew how many.

X Q. 1817. At this time had you decided on a type of lamp as being the one that you intended to introduce?

A. We had decided upon several which we thought were suitable for introduction.

X Q. 1818. Any one that you preferred?

A. There were two forms which we preferred; possible three; one was a straight pencil carbon; the other was the loop or arch form carbon; another was a carbon held straight across the tops of the holders with adjustable tension between the holders.

X Q. 1819. Now, these lamps that were made by you in conformity with the large order of the company—what kind of carbons did they have, and what was their form?

A. The carbons were straight pencils or strips of pure-deposit carbon, some hollow and some solid arched carbons of pure-deposit carbon; some of the same of both shapes with a core of wood or other fibrous carbon inside; some of both shapes of wood or other fibrous carbon treated according to our electrical process to 1512 all extents, from a treatment barely sufficient to drive out occluded gases, purify the carbon, render its resistance uniform throughout its length and regulate the resistance to conform to other carbons of the same kind, up to a treatment making a substantial deposit of appreciable thickness upon the fibrous core; some of these carbons of both shapes were substantially round in their cross-section, some of them were flat and thin and some of them were square, or nearly so, in cross-section.

X Q. 1820. This order was the first commercial order that was given for Sawyer-Man lamps, and the lamps to which you have referred were made in response to it?

A. I think so; that is, it was the first direction given by the company to make lamps for commercial use.

X Q. 1821. How did it happen that there was such a variety and difference in the shape and substance and treatment of the carbon and such difference in the construction of the lamps as must have been necessitated thereby?

A. I do not think that there was anything strange about it when it is considered that the superintendent of the work was an inventor and desired to make the lamps in a variety of forms rather than one.

X Q. 1822. What do you mean, that it was left to you and Sawyer to make such lamps only as you saw fit, the number only being ordered?

A. I mean just what I say; that these different forms of lamp having been made before that time or projected and the different forms and characters of carbon having been tried; the order of the company was given to make the lamps, and the character of the lamps to be made was not specified; I will add that there was another reason for this, I mean the not settling down to one particular form of lamp and carbon—a thing that I personally greatly desired to accomplish.

X Q. 1823. Then the order of the company left it to you 1513 and Sawyer to decide upon the kind of lamp that should be made and the shape and character of the carbon to be used?

A. Yes.

X Q. 1824. Why then did you make lamps containing the differences you have mentioned?

A. I suppose to try upon a large scale which was the best.

X Q. 1825. You say "suppose," don't you know?

A. I know that that was all the reason I had for doing so, or consenting to its being done.

X Q. 1826. Then at this late day, you had not determined which was the best form for the carbon or the best material?

A. Yes, I think I had.

X Q. —. You say you "think," don't you know?

A. Yes, I believe I had.

Adjourned till Tuesday, the 13th inst., at $10\frac{1}{2}$ a. m.

1514 NEW YORK, *Dec.* 13, 1887.

Met. Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1828. If you were satisfied at this time of the superiority of one kind of carbon over the others, what is your explanation of making lamps of those carbons that you knew to be inferior, the lamps having been intended, as you say, for commercial use?

Objected to as immaterial and not cross-examination.

A. Prior to the giving of the order or direction by the company for making a large number of lamps for commercial purposes we had made a number of lamps of each of the kinds of carbons that I have described, all of which were good and satisfactory lamps; I had my own ideas and preferences in regard to the carbons in these different lamps: I endeavored to have them carried out after these orders were given; my own time was greatly absorbed by my business in charge of trust estates and property, where I was handling hundreds of thousands of dollars and had charge of millions of dollars' worth of property, real and personal; and I was worn out with the work of that and in the workshops of the Electric Dynamic Light Company, so that I could not give as much attention to the work there as I had previously done; and in December, 1878, was obliged to substantially give up work in the shop and get through the company Mr. Lawrence Myers to go to the shop and stay there continuously, and try to keep Mr. Sawyer sober; Mr. Sawyer's habits of inebriation grew on him to such an extent as to seriously interfere with his duties and work as superintendent of the work of the company; I did not succeed in having my ideas carried out, and Mr. Sawyer's condition was such that 1515 systematic and continued work upon what, previous to that time, had been considered the best carbons was not uniformly continued by him; it was due, *I as* think, to Mr. Sawyer's habits and the result of those habits in bad workmanship and carelessness in work where the utmost particularity and care was required, as it is to-day, in the manufacture of incandescent lamps, that the work was not as systematic as it should have been and as I desired it to be, and that the best, or what we considered the best, carbons were not made and put into use more extensively in the lamps we built.

Answer objected to as irresponsive and as containing many matters that are immaterial, as to which the testimony is incompetent and others in respect to which he has not been interrogated.

X Q. 1829. I want you to tell me how it happened that in filling this large order for lamps intended to be used commercially, carbons of different materials were used, some of which you believed so be inferior to others?

Objected to as having been already answered.

A. I have already fully answered that question, that it was due to Mr. Sawyer's being drunk, neglecting his work and making bad work, &c., being capricious, unmanageable and incompetent to exercise good judgment, and to my inability to be present at the workshops, as I had been before.

X Q. 1830. What had these facts to do with making the carbons of different material? I can understand how his intoxication could have interfered with his workmanship or prevented the work from being of the best kind; but how does it account for the making the carbons of these lamps intended for commercial purposes of such different materials which I should suppose would require a greater amount of work than if they were all made of one?

A. Mr. Sawyer was the superintendent; he gave directions
1516 to the work; his bad workmanship and judgment when drunk
and his carelessness while in that condition, resulted in the failure of many lamps, obscured what had previously been well settled and ascertained in our joint judgment; and led him to make first one thing and then another to remedy the defects which caused his failures, and so it was that he continued to put all kinds of carbons that we had made in the lamps, first one and then the other, and I was not there, and could not be, to control, if I could have done it, if I had been there.

X Q. 1831. You did not then participate in the making of these lamps?

A. Yes, to some extent; but not to a great extent, or as great an extent as I had before.

X Q. 1832. You did not approve of the use of these different carbons in the lamp, then?

A. Yes; sometimes I did and sometimes I did not.

X Q. 1833. You understand I am speaking of the filling of this order?

A. Yes; it would be more proper to say that I acquiesced in it, because I could not help it.

X Q. 1834. You were cognizant, then, of how the order was being filled as it progressed?

A. Yes, I think I was as fully as I was able to keep myself informed, but I could not keep myself fully informed of the work that was going on in all its stages.

X Q. 1835. You say that sometimes you approved of putting different carbons in these lamps and sometimes not; please explain what you mean?

A. I mean that we had made good lamps with all these carbons, and that when Mr. Sawyer told me of his failures of some of the lamps made with any of the kinds of carbons, or I observed those failures myself, and Sawyer told me that he was making lamps with different carbons, and believed that he would not make so many failures with the other kinds of carbon, I acquiesced in his
1517 going on with it, sometimes, and sometimes I protested and tried to keep the work uniform.

X Q. 1836. What fact or circumstance would influence you in acquiescing or protesting?

A. I don't recollect what particular facts or circumstances did at any particular time or instance; I only recollect that I was anxious to get a large number of lamps that were good and satisfactory, completed—more desirous of this than of testing or exploiting any particular carbon in the lamps.

X Q. 1837. So you practically let Mr. Sawyer go ahead as he saw fit?

A. Yes, if he would make good lamps.

X Q. 1838. Leaving to him to determine how good lamps should be made?

A. No, we had made good lamps in large numbers before, and the patterns were before him and in use.

X Q. 1839. But the fact is he went ahead, making lamps having carbons of different shapes and different materials, some of which were better than others?

A. Yes, I thought so.

X Q. 1840. But you allowed him to go ahead and make the inferior carbons and shapes as well as the superior?

A. So long as he would make good lamps we urged him on to do it, irrespective of the kinds of carbons or their shapes.

X Q. 1841. Now, had Sawyer, at this time, a decided preference for one shape or kind of carbon?

A. I don't know; I don't think he was capable during a great part of the time of exercising intelligent judgment in the matter.

X Q. 1842. What I want to know is whether he had formed a judgment?

A. He had before this time formed a judgment, and expressed it to me.

1518 X Q. 1843. Is it your believe that at this time he had a preference?

Ans. I don't know.

X Q. 1844. Do you mean to say that at a time when you claimed the experimental stage of your work was over, that you were ready to manufacture lamps for commercial use, and an order had been given by the company for the manufacture of a large number of the lamps, and you and Sawyer were manufacturing them, that you don't know whether your coworker and co-inventor had a preference for one kind or shape of carbon over another kind or shape?

A. I mean to say that at this time, while the manufacture of these lamps was going on, that had been directed to be made by the company, that my coworker, Mr. Sawyer, was not usually or ordinarily in a condition to exercise intelligent judgment upon the matter, and that he expressed himself in such various and contradictory ways to me—one thing to-day and another to-morrow—that I could form no opinion as to his having preference one way or the other, except temporary, and not reasonable and permanent.

X Q. 1845. If such were his conditions, why did you entrust the manufacture of these lamps to him?

A. We could not help ourselves; no one else except I was educated in the work; he made many good lamps, and we wanted to get lamps made, as I have stated before.

X Q. 1846. Then, is this the fact, that Sawyer was not so drunk or so unintelligent that he was not capable of making or superintending the making of good lamps—lamps which you intended to sell and use commercially; but that he was so drunk and so unintelligent as to be incapable of selecting the best kind and shapes of carbons, that having been a matter upon which you and he had already decided?

A. If I permit you to testify for me, I should convey very
1519 curious ideas, it seems to me. I have stated that Mr. Sawyer's inebriate habits interfered with his work in the making of the lamps, and caused him to make failures in their making; that while he made good lamps he also made bad ones; that his failures obscured in his mind what we thought had been previously made clear; the preference for carbons which we had been agreed upon in opinion; that his mind was rendered vacillating, as any drunken man's is: that I could form no intelligent opinion in regard to his then preferences, by reason of such vacillating.

X Q. 1847. If you could have had your way, would the lamps all have had one shape and one character of carbon?

A. Yes; unless that shape and that character had proved unsuccessful in use.

X Q. 1848. Had your experiments reached such a point that you had a decided preference for one shape and material?

A. Yes; one general shape, and of one material treated.

X Q. 1849. And if you could have had your way these lamps would have all been of that shape and material?

A. Yes, if the first had proved successful lamps.

X Q. 1850. What do you mean by saying "if the first had proved successful lamps"? Was not your mind sufficiently made up at that time?

A. My mind was made up. I mean by "first" the first lamps set up and run of those made under that order.

X Q. 1851. Was it sufficiently made up to have made all the lamps after one model, and having one kind and shape of carbon?

A. It was.

X Q. 1852. But yet, if the first instalment of lamps made up under this order had not been good, would you have changed the shape and material of the carbon?

1520 A. Yes, one or both unless the failure should have been due to some cause outside of the carbon. If we had deemed the failure due to the shape or material of the carbon, the shape or material would have been changed.

X Q. 1853. Had you then learned so little from all your experiments, that you would at this time, have changed the shape and material of the carbon, if the first instalment of lamps had been a failure which you attributed to the shape of material?

A. I will answer this by saying that I had no fear of failure by reason of the shape or material of the carbon, but that at any time we would have adopted a better shape and a better material which we could control as would be done to-day in incandescent electric lamps.

X Q. 1854. Then you do not think it possible that you could have attributed any failure in the first instalment of lamps to the shape or material of the carbon, if they had been made of the shape and material you preferred?

A. I do not think it probable that I would have attributed the failure of the first lamps to the shape or material of the carbons if they had been properly prepared and made.

X Q. 1855. What shape and material did you prefer?

A. I preferred a carbon of fibrous material electrically treated, of a form rising above the holders, of an arch or loop shape.

X Q. 1856. What kind of fibrous material?

A. I think paper fibre or paper carbon were my preference at this time, next wood carbon of willow.

X Q. 1857. What kind of paper?

A. Paper that was pure and had not remaining in it anything but cellulose.

X Q. 1858. Please mention the name of such paper?

A. The nearest paper of that kind in ordinary use is white blotting paper, or paper similar to it, unsized paper, of clean, pure paper stock.

1521 X Q. 1859. You say you preferred fibrous material treated to what extent?

A. Treated, as I have stated, to the point where the resistance of the carbon throughout its length would be rendered uniform, and to the point where there would not be so much of the deposit carbon on it as to render it liable to fly to pieces, as pure-deposit carbon does, when suddenly heated up. This treatment in our practice simply gave the carbon a silvery or lustrous appearance, and did not apparently change its dimensions.

X Q. 1860. Some two hundred lamps were made pursuant to this order, were there not?

A. I should think so, perhaps not so many.

X Q. 1861. How many of such lamps had loop or arch-shaped carbons?

A. Few comparatively, perhaps fifty; that is my best judgment.

X Q. 1862. The others were straight carbons?

A. Yes.

X Q. 1863. How many of these two hundred lamps had conductors of fibrous material?

A. I don't know.

X Q. 1864. What is your best recollection?

A. At this date I should simply have to guess. I should think from a third to a half, perhaps not so many. They were not near so many as those having mineral carbons or deposit carbons.

X Q. 1865. Who made the carbons for these lamps?

A. Mr. Edward Myers did the carbonizing mostly. Mr. Sawyer did the treating.

X Q. 1866. Edward Myers is dead, is he not?

A. He is.

X Q. 1867. Where was the carbonizing done?

A. In the furnace of the steam engine at 94 Walker street; our own furnace in our own room.

1522 X Q. 1868. Who did the mechanical work on these two hundred lamps?

A. It was done all over town in different places.

X Q. 1869. Tell me the places.

A. That I don't know; the metal spinning was done at three or four places in Centre street; the glass-work was done at the factory in Brooklyn near South 7th-street ferry; the carbon-work other than the incandescent carbons was done at two or three different places; the soapstone discs were done by a soapstone man down in the vicinity of Water street, and I think Peck slip, in that neighborhood; the metal-work was part of it done by H. L. Judd & Co., in Brooklyn; part of it was done by different mechanics in Centre street, one was a firm, I do not recollect their names, in the top story of the building at the corner of Howard and Centre street-; the setting up was done at our shop, 94 Walker street.

X Q. 1870. What persons or mechanics assisted in the assembling of these lamps at 94 Walker street?

A. Mr. Wm. Sawyer, who is now dead; Mr. George Sawyer, Mr. Wm. Sharp, Mr. Edward Myers and Mr. Wm. E. Sawyer.

X Q. 1871. The only persons living are Geo. Sawyer and Mr. Sharp?

A. I think so.

X Q. 1872. They ought to know then the mechanical character of these lamps, and whether they had straight or circular carbons?

A. I don't know whether they would or not.

X Q. 1873. If they put the work together they ought to?

A. I don't think they ever put the carbons in the lamps.

X Q. 1874. Could they not tell from the holders whether the carbons were to be upright and straight or horizontal or curved?

1523 A. They could tell whether the carbons were to be set upright or horizontal, not whether they were to be curved or straight.

X Q. 1875. Were the various parts of these lamps made from drawings or models?

A. I think they were made from drawings and samples both.

X Q. 1876. Did you give any of the instructions to the mechanics, or furnish them with the drawings or samples?

A. Yes, I think so, but it was mostly done by Mr. Sawyer.

X Q. 1877. Give me the names of any persons whom you thus gave information to or instructed?

A. H. L. Judd & Co., the glassmen in Brooklyn, I don't know their names, and the soapstone man whose name I do not remember; I probably gave directions to others, but I do not at present recollect their names. I remember one, one other to whom I gave instructions and models for castings in brass, but I don't remember his name; his location was a brass foundry near the Five Points, New York; I remember also being at two or three metal-spinners' with reference to the work; I do not remember their names.

X Q. 1878. What kind of fibrous material was it that was used in these lamps?

A. Mainly paper and wood.

X Q. 1879. To what extent was it treated?

A. Some of them were treated with a view of the removal of the fibrous carbon to leave pure-deposit carbon for the incandescent conductor of the lamp; some of them were treated so as to make a visible coating of appreciable thickness upon the conductors; most of them were treated to the extent I have specified or approximating that as in accordance with preference as stated to-day.

X Q. 1880. What was the extent of that treatment; I
1524 mean, was it sufficient to fill up the pores of the material
and coat it.

A. No, it left the material still porous, its ultimate fibres were, of course, coated, but the coating was infinitely thin except where points of higher resistance were regulated in the process to make the conductor uniform in resistance throughout its length.

X Q. 1881. How many of these two hundred lamps had conductors of carbonized paper or wood treated to this slight extent?

A. That I do not recollect.

X Q. 1882. About how many?

A. I did not do the work and I do not know.

X Q. 1883. Have you no idea?

A. No, not to express it in numbers; I can guess, I should think more than half of the fibrous carbons were treated, or intended to be, in that way.

X Q. 1884. What is your best recollection as to how many of these two hundred lamps had fibrous carbons treated to this slight extent?

A. I have no recollection which would enable me to fix the number; I can guess.

X Q. 1885. Well, guess, if that is the best you can do.

A. I should think thirty or forty lamps, maybe more, rather more than less.

X Q. 1886. I understand that some of the straight carbons were fibrous and some not, and some of the loop-shaped carbons were fibrous and some not?

A. Yes.

X Q. 1887. Who now living knew that some of these two hundred lamps contained these fibrous carbons treated to this slight extent?

A. I think that Mr. George Sawyer and Mr. Lawrence Myers

knew of it at the time, and that the other gentlemen, the two Messrs.
Hays and Mr. Classon were told of it; I think Mr. Amos
1525 Broadnax knew of it, and I knew of it; how much the
others can recollect of it at this time I do not know.

X Q. 1888. What has become of these two hundred lamps?

A. Part of them I have, one or two; a part of them Mr. Sawyer took when we left Walker street; part of them were put up, packed in barrels, and left with me at the time when we left 94 Walker street; part of them Mr. Sawyer subsequently got from me for making exhibitions and never returned; part of them were used up in our workshop in lighting them, the shops, up; part of these were used up in running them in exhibitions, experiments and testings at our place, 94 Walker street; part of them were taken down and modified by Mr. Sawyer.

X Q. 1889. Do you know whether there is now in existence one or more of these lamps containing a fibrous carbon conductor treated to this slight extent?

A. I do not; I think there is.

X Q. 1890. Where?

A. I don't know where.

X Q. 1891. Were these two hundred lamps paid for by the Electro Dynamic Light Co.?

A. They were, all the work.

X Q. 1892. Are there no books or papers in existence that would show who was paid for the work and who did it?

A. There were books and papers and bills which would show who was paid for part of it, not all.

X Q. 1893. Where are they, and in whose possession?

A. I don't know; the last I saw of them they were in the possession of the company.

X Q. 1894. What person had the custody of them?

A. I think the last time I saw them they were in the custody of Mr. Lawrence Myers or Mr. Jacob Hays.

X Q. 1895. Were these two hundred lamps delivered to the company, and were they its property?

1526 A. They were in the company's shops and were its property; there was no formal delivery of them.

X Q. 1896. Why did you in no way in the interference case mention or refer to this large number of lamps which you now say were made, and which had conductors of fibrous material and were made for commercial use?

A. I don't know whether I did or did not so refer to them.

X Q. 1897. The fact would have been important, would it not?

A. I do not know; it is proper to say that I have not stated here that these lamps were put to any use, except that of the company, or use made of them by Mr. Sawyer after March, 1879. This reminds me that I think some of these lamps were taken by Mr. Sawyer to Ansonia, Conn., to Mr. Wallace's place; I don't know whether those taken there had fibrous carbons in them or not.

X Q. 1898. Why was not one of these lamps containing a fibrous cabon put in evidence in that interference?

A. That I don't know.

X Q. 1899. Why were not the people whom you say knew of them interrogated concerning them in that interference?

A. I really cannot tell why anything was not done.

Mr. Broadnax, of counsel for complainant, says, that "you" (witness) might say that there was enough before the Commissioner to satisfy him (Commissioner) that Sawyer and Man were the first inventors, and that that is a good reason why there was nothing more put in.

X Q. 1900. These two hundred lamps having been made for commercial purposes, what generator of electricity did you intend to use with them?

A. We intended, when we should introduce the lamps into uses other than our own, to have dynamos built to run them.

1527 X Q. 1901. These two hundred lamps, under what conditions of current and electro-motive force were they constructed to be used?

A. I do not know, for they were of very variable resistance.

X Q. 1902. Were they not approximately of one resistance?

A. No.

X Q. 1903. Were they not adapted for use approximately under the same conditions?

A. Not in the same numbers, nor in the same arrangements.

X Q. 1904. Were they intended to be run in series?

A. Yes, some of them, a series of from eight to twelve lamps.

X Q. 1905. Were they not constructed in reference to some definite system or arrangement?

A. No, they were not, except in the limited numbers of from four to twelve, and some of them for use as single lamps.

X Q. 1906. Between what limits did the resistance of these two hundred lamps vary?

A. That I cannot tell in regard to any of our lamps; I know that some of them were less than an ohm and some of them, I think, were from thirty to fifty ohms, and perhaps higher.

X Q. 1907. Why was there so great variance in the resistance of these two hundred lamps?

A. It was an eminent illustration (these lamps two hundred, more or less) of the want of systematic work due to the condition of Mr. Sawyer, as I judged at the time, and of his inability by reason of inebriation to discriminate and judge and plan and adopt and adhere to system and regularity, and of the combination by Mr. Sawyer of work more in the character of experiments than for one particular purpose and in one particular plan.

1528 X Q. 1908. Was this wide difference in resistance due to accident or design?

A. I think it was due to design.

X Q. 1909. Your design?

A. No, design on Mr. Sawyer's part.

X Q. 1910. Had you any desire or preference as to what the resistance of these lamps should approximately be?

A. I will answer that question by saying that I have never determined in my own mind what the most advantageous resistance in an incandescent electric lamp is or should be.

X Q. 1911. Please answer my question by telling me whether you had any desire or preference as to what the resistance of these two hundred lamps should be.

A. Not any fixed resistance, that is, I had determined no such resistance in my mind.

X Q. 1912. Had you any preference or wish as to what about the resistance should be?

A. I have answered that question as fully as I can.

X Q. 1913. Do you mean that you were indifferent as to whether they were a tenth of an ohm or a hundred ohms?

A. No; I do not mean that.

X Q. 1914. Were you indifferent as to what their resistance should be?

A. No, I wanted them of suitable resistances.

X Q. 1915. What did you then consider suitable resistances?

A. Very various, as I do to-day.

X Q. 1916. Did you want these lamps then to very in resistance?

A. Yes, a little.

X Q. 1917. Did you then think Sawyer had done well in making them of different resistances?

A. No, not as they were made.

1529 X Q. 1918. Do you mean that you approved of the variance in resistance, but did not approve of the means by which it was obtained?

A. No, I do not mean that generally.

X Q. 1919. What was the resistance of the great majority of these lamps, about?

A. I do not know; I should judge from one to five ohms.

X Q. 1920. Had Sawyer any opinion at this time as to what about was the most desirable resistance in an incandescent lamp?

A. I do not know or recollect.

X Q. 1921. Had Sawyer and Man as joint inventors?

A. At that time when these lamps were built I do not *that think* we had or agreed upon anything as a fixed desirable resistance.

X Q. 1922. Had you agreed upon anything approximately?

A. At this time I do not think we consulted together in regard to it.

X Q. 1923. Now these lamps you say were made for commercial use; that being so, had you no idea of the character of the dynamo they were to be used in connection with?

A. Excuse me; I did not say they were made for commercial use; I said they were ordered to be made with the intent to have them used commercially. The lamps which we did make could all of them be run with the dynamos and other appliances we had.

X Q. 1924. Were the lamps made for commercial use or were they not?

A. We made them with a view of having lamps for commercial use. They were many of them lamps suitable to be used commercially in various positions and in various arrangements.

X Q. 1925. You did not make them then with reference
1530 to any approximate condition of current or electro-motive
force?

A. We made them for use with various currents and various electro-motive force, as I have stated.

X Q. 1926. Were any of these lamps ever sold for use commercialiy?

A. I don't know of any unless it was the lamps that were taken to Ansonia. I think they were paid for by Wallace.

X Q. 1927. What do you mean by saying they were paid for by Wallace, that he took them as part of your experimental plant?

A. No, Mr. Wallace did not take our experimental plant, except a dynamo, as I recollect. That belonged to me and I lent it to him.

X Q. 1928. Did the Electro-Dynamic Light Co. ever order any lamps to be manufactured other than these two hundred and subsequent thereto?

A. My recollection in regard — that matter is, that two or three directions were given by the board for the manufacture of specific lamps. They were some of them, I think, made and set up, but they would be included in my estimate or guess of two hundred lamps made.

X Q. 1929. With the exception then of this lot of two hundred lamps more or less of which we have been speaking, your recollection is that no other lamps were made than the few specific lamps referred to in your last answer?

A. No, that is not my recollection. The few specific lamps are included in my estimate of two hundred lamps made after the first direction given by the company. Before any specific direction was given by the company we had made, as I stated before, a considerable number of lamps of all the different varieties I stated. This is not included in my estimate of the number of lamps made after the direction of the company to make a specified number.

1531 X Q. 1930. Did the making of these two hundred lamps,
more or less, in *the* pursuance of the order of the company,
practically complete the work of Sawyer and Man?

A. Yes, practically, the making of the lamps which I have estimated at about two hundred, after the direction of the company to go on with the manufacture practically, completed the work of Sawyer and Man together.

Adjourned till Wednesday, the 14th, inst., at 10½ a. m.

NEW YORK, *Dec. 14th*, 1887.

Met pursuant to adjournment. Present, counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1931. In your 1887th answer, you say that you have one or two of these lamps made in Walker street pursuant to the order of the company; will you produce them at the next sitting?

A. I will, if so instructed. I am unwilling to give these lamps out of my custody. I had a complete assortment of all the lamps including all the different shapes of carbons and different kinds of carbons including fibrous carbons of different kinds, and they have got them all away from me except these, among others one that I set up with my own hands at 43 Centre street and which was used as an exhibit in some of the cases and they are all used up, broken and lost so far as I know; and I do not propose to give up the last remnants which I have of my work.

X Q. 1932. Will you bring such lamps as you have with you at the next sitting?

A. Yes; if so instructed.

X Q. 1933. You went to 94 Walker street the last of September, 1878, and remained till the latter part of March, 1879?

1532 A. Yes.

X Q 1934. And experiments were conducted there during that time?

A. Yes.

X Q. 1935. Was any carbonizing done there?

A. Yes.

X Q. 1936. While at 94 Walker street did you carbonize any at your house?

A. I do not remember; it is probable that I did, but the bulk of what was done was done at the shop.

X Q. 1937. Who did it usually?

A. I did some Mr. Edward Myers did—the most of it, I think Mr. Sawyer did some.

X Q. 1938. Who now living knew of its being done there?

A. I think all that I have mentioned as being at the shop, including our workmen and Mr. Church, Mr. George Sawyer, Mr. Sharp, Mr. Lawrence Myers, Mr. Amos Broadnax and myself, and Mr. Wm. H. Church. There are probably, a large number of other persons that saw it, but I don't know.

X Q. 1939. Who assisted in the work at 94 Walker street?

A. Mr. William E. Sawyer, George Sawyer, George W. Sawyer, Sharp and men who were employed by the day, but who they were I don't remember.

X Q. 1940. So far as experiments on the lamps were concerned at 94 Walker street, what direction did these experiments take?

A. Before going to 94 Walker street we had ordered and got delivered in part glass globes and bases of different sizes and shapes, and the leading-in conductors with their apparatus, spun caps for covering the base of the lamps of different sizes, the convoluted or folded conductors beneath the diaphragm, their connections through the base of the lamp, diaphragms, screws and carbons, and an
1533 assortment of a metal of different sizes and shapes for making
holders and parts above the diaphragms of the lamps; we had given orders for the making of a dynamo, and generally had prepared more thoroughly than before for the commencement of work on our lamps, switches, &c., bought and prepared electrical apparatus, resistances and measuring instruments; our first work was directed to the manufacture of the several different kinds of lamps I have

mentioned as manufactured or made before the direction given by the company to proceed with the manufacture of a large number of lamps, in order to get good lamps, improve their shape and appearance, and settle down upon all the different parts of lamps for different uses and of different kinds; to the preparation and testing of different kinds of carbons and their adaptability for use in different lamps as incandescent conductors; meantime the testing and trial of different dynamos went on and testing and trial of different methods of treatment and different extent of treatment of the incandescent carbon conductors; at the same time we were preparing switches, regulators, and resistances and automatic cut-outs, and doing the electrical experiments and work of testing and measuring; after we had got a sufficient number of lamps ready they were exhibited to the officers of the company—the directors, stockholders and their friends; matters having progressed so far, the direction of which I have spoken was given by the company to proceed to the manufacture of a large number of lamps, and the work of making and setting up lamps and the other work I have spoken of was continued; the materials for the large number of lamps I have spoken of as directed to be made were contracted for and procured in whole or in part from a great number of different people. I have omitted to mention the very extensive work which was carried on with reference to the atmosphere of the lamps, commenced at 43 Centre street, carried on more extensively during the last days of August and in September, until we went to 94 1534 Walker street, while we were at the corner of Howard and Centre streets; this work involved extensive chemical apparatus and materials and means of exhausting the chamber of the lamp and was carried on in part in our own shops, in part at Stevens institute, Hoboken, in part at the School of Mines in New York, and in part at a place in Broadway, down near the Battery; this is a general description of the work up to the time in November or December, 1878, when I was obliged to give up working so much and giving so much of my time to the work of the company; after this time much the same kind of work was continued under the superintendence of Mr. Sawyer, with my attention only so far as I was able to give it from time to time up to the time in March when we left 94 Walker street.

X Q. 1941. From whom were the globes, bases, leading-in conductors with their apparatus, spun caps, the convoluted or folding conductors, the diaphragms, screws and carbons mentioned in your last answer ordered and obtained?

A. I have already answered that question as completely and fully as I can.

X Q. 1942. You only remember the name of Judd & Co.?

A. Yes, none other occurs to me now.

X Q. 1943. To whom was the order for a dynamo given referred to in your last answer?

A. Arnoux & Hochausen.

X Q. 1944. Was the machine made?

A. Yes, but not before we got to 94 Walker street.

X Q. 1945. Was this the machine you principally used at 94 Walker street?

A. Yes, I think so; I do not know but that another was substituted for it of a similar kind.

X Q. 1946. What has become of this machine?

A. I think it is at Mr. Wallace's place at Ansonia, Conn.; I lent it to him.

1535 X Q. 1947. Can you tell me approximately its capacity or construction?

A. No.

X Q. 1948. Was the machine a special design, or one of Hochausen's regular make?

A. In general appearance it resembled the arc lighting machine which they were then building.

X Q. 1949. How did it compare with them in capacity—do you remember?

A. I object to further use of my time in repeating testimony already given; only that it was of less electro-motive force.

X Q. 1950. You say, in your answer to the 1939th question:

"After we had got a sufficient number of lamps ready, they were exhibited to the officers of the company, the directors, stockholders and their friends."

Did any of these lamps contain fibrous carbons but slightly treated, either straight or in the loop form?

A. Yes, some of those we exhibited contained the fibrous carbons treated in a slight way.

X Q. 1951. Were the persons to whom they were exhibited told the nature of the carbons?

A. I think the officers and directors of the company were told in regard to it, but I do not know.

X Q. 1952. Mention such persons as are now living that you think were told?

A. I think the two Messrs. Hayes, and Mr. Myers, and Mr. Church; I know Mr. Broadnax was told in regard to it, and that it was exhibited to him, and that he was applied to early in October by me to apply for patents for the fibrous carbons.

X Q. 1953. What was the material of the conductor of the great majority of the lamps made at Walker street?

1536 A. Either mineral carbon or deposit carbon, as I have said a great many times.

X Q. 1954. Had the majority of lamps made there straight or circular carbons?

A. Straight.

X Q. 1955. Were the lamps with straight carbons substantially such as shown in your patents?

A. In general appearance the same; they did not have the support G, shown in the first patent; they more nearly resembled the figure 8, shown in that patent, and were more like the lamps shown in the patent 210,809, except that some of them had straight carbons extending horizontally across between the holders; these last were of the same general construction of the lamps with looped or arched carbons, the only difference being compensation for expansion and contraction of the incandescent carbons.

X Q. 1956. About how many lamps in all should you say were made at 94 Walker street?

A. I have already stated that I do not know the number, and can only guess at it, but I should judge somewhere between two and three hundred—about two hundred and fifty or sixty would be the minimum idea in my mind of the number, and it may have been very much more than three hundred.

X Q. 1957. What is your explanation of the fact that the majority of the lamps made in Walker street had straight carbons, if, as I understand the fact to be, you had made lamps with circular carbons, which was a better and cheaper construction?

A. There are several things which occur to me in this connection; one was that we had not applied or got the application made for the fibrous carbons and the loop shape, which we then considered belonged to us, and were in doubt, under the advice given by counsel, whether the invention was patentable; another was that,
after we commenced the manufacture of lamps, Mr. Sawyer's
1537 condition was such, from inebriation, that he was not capable of exercising good judgment in regard to the matter, and
Mr. Sawyer was the superintendent in charge of the work.

X Q. 1958. What is your explanation of the fact that the majority of lamps made at Walker street had conductors made of hard or deposited carbon, if it be true, as I understand you to say, that fibrous carbon was the better carbon and the easier to make?

A. Before going on to the making of our largest number of lamps, as I have stated, I think Mr. Sawyer and I were agreed in opinion as to the fibrous carbon and the loop form being the preferable one; when the larger number of lamps were being set up by Mr. Sawyer and tested, he set up a considerable number of lamps of this form with this carbon and tested them, and many of them failed, perhaps a majority, through, as I believe, no defect in the carbon or their shape, but to unskillful manipulation in the setting up of the lamps. He was not in a condition to exercise good judgment in regard to them, and discriminate in regard to the causes of his failures. This rendered him vacillating and changing. He then went on to set up lamps with straight carbons with much the same result. He changed the forms and interior works of the lamps from what we had settled upon. I think as a whole, he preferred the straight carbon lamps at that time, and built them mostly, although not entirely, and I think that he preferred on the whole the deposit carbons for conductors, and used them mostly, but not entirely. I could not give directions to the work nor have it carried on, nor control it as I wanted to. As I said, Mr. Sawyer's opinion was one thing to-day and another to-morrow. I was, as I have said before, and the company was, more anxious to get good lamps built in large numbers, than to work out and determine the absolutely best form of lamps, and in order to do so we let Mr. Sawyer do as he pleased in a large measure. And to this answer I desire to add as a reason, the whole of my last previous answer.

1538 X Q. 1959. An arrangement has been referred to that was made with Wallace of Ansonia; will you please state what that arrangement was and what was done in regard to it?

A. In the spring of 1879, the Electro Dynamic Light Co. granted an exclusive license to the Wallaces of Ansonia, for the manufacture and sale of all our patented appliances and inventions up to that time, coupled with an agreement on the part of Mr. Sawyer to go to Ansonia and instruct the workmen and superintend the building of lamps and other apparatus, and putting them in operation, for which Mr. Sawyer received payment from the company or its stockholders, and Mr. Thomas Wallace became president of the Electro Dynamic Light Co., and Mr. Edward Myers, who *who* been in the employ of the company up to that time, from, I think early in September, 1878, was employed by the Messrs. Wallace to assist in the work. The Wallaces were to pay royalty to the company for every lamp put out, and to build and put out a large number of the lamps. The Wallaces went on and commenced to work, and got ready the parts for a large number of the lamps, but Mr. Sawyer's conduct was such, and his habits so bad, as I understand from him and Mr. Wallace, that they could not get along with him, and finally turned him out, and went on with the work with Mr. Myers in charge. Mr. Myers was taken sick some time in the fall of 1879, lingered along, expecting to return to the work which was held in waiting for him, and finally died without returning, at his father's house in Plattsburgh, New York. There was no person educated to the work and who could go on with it as Messrs. Wallace claimed, whom they could get. The matter lingered along and no work was done by, or under the Electro-Dynamic Light Co. until finally a consolidation was made with the Eastern Electric Manufacturing Co. and the patents and inventions were assigned to that company and the Messrs. Wallace surrendered their license.

Adjourned till Thursday, the 15th inst., at 1 p. m.

1539 THURSDAY, *December* 15, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 1960. Did Wallace ever make any lamps?

A. I don't know whether he ever completed any or not; I was not there.

X Q. 1961. What was the general model of lamps that was to be made by Wallace?

A. I don't know; I suppose all the different kinds.

X Q. 1962. What carbons were they to have?

A. I do not know; all the different kinds of carbons that the Electro-Dynamic Light Co. owned, I suppose.

X Q. 1963. Of what shapes were the carbons to be?

A. I don't know.

X Q. 1964. Who was to decide on all these matters?

A. The Messrs. Wallace.

X Q. 1965. Did the Wallaces know the preferences of the inventors, and what constructions they considered best?

A. I think Mr. Thomas Wallace knew what had been done. I am not certain of that. The lamps were exhibited to him and his representatives by Mr. Sawyer, at No. 94 Walker street. I was not present and don't know what Mr. Sawyer told him. I remember before the arrangement was completed of only one conversation with Mr. Wallace. I do not remember expressing any preferences to him in regard to the carbons or their material. I do remember having expressed a preference for the incandescent lamps, over the semi-incandescent or feeder lamps.

X Q. 1966. Did you ever inform the Wallaces, or did the company ever inform them, as far as you know, that you preferred a conductor of fibrous material slightly treated?

1540 A. I don't remember ever having expressed myself to that effect to Mr. Wallace, and think it very unlikely that I would do so at the time, nor do I think that any such preference was stated to him by the company.

X Q. 1967. Did you ever inform the Wallaces, or were they ever informed by the company, so far as you know, that you preferred a loop or arch-shaped carbon, to a straight carbon?

A. I do not remember. I think it probable that I may have done so to Mr. Thomas Wallace, but I do not recollect that I did.

X Q. 1968. What had the Wallaces then to guide them in the manufacture of these lamps, that they were to undertake?

A. Mr. Sawyer's experience and that of Mr. Myers, and sample lamps, I think. It is proper to say that the Messrs. Wallace were largely engaged in electrical work, and as I understood, had done a large amount of experimenting and other work in electric lighting, and their own judgment in such matters I suppose would guide them.

X Q. 1969. By Sawyer's experience do you mean his statements in regard to his experience, or such as he chose to give them?

A. I mean just what I say: Mr. Sawyer was hired to go up there and aid them in the work.

X Q. —. Hired by the Electro Dynamic Light Co.?

A. Hired under the agreement made with Mr. Wallace, the compensation for his services coming from contributions made by the company and its stockholders.

X Q. 1971. The Wallaces personally did not know what his experience had been, but depended on him for information; am I right?

A. I have stated all I know about that matter.

X Q. 1972. Were you one of the stockholders that contributed for the payment of Sawyer's expenses?

A. Yes.

1541 X Q. 1973. Did you inform the Wallaces or did the company, so far as you know, of Sawyer's habits of intoxication and of your experience at 94 Walker street, in the manufacture of the two hundred lamps, as to which you say he was incapable of exercising good judgment, and was changing about from day to day?

A. I do not think I had any opportunity to do so before the arrangement with them was completed, and therefore think I could not have done so, nor do I think the company did or had any opportunity to do so.

X Q. 1974. In your 1967th answer you speak of sample lamps that you think Wallace had to go by. Are you quite confident that he had sample lamps?

A. I only know that sample lamps were furnished by the company to Mr. Sawyer for use at the Wallaces'; and I know in the fall following that a claim was made upon Mr. Wallace by Mr. Sawyer for lamps which he claimed the company had given to him, and which I think Mr. Wallace settled with him, rather than to have a fuss. Of this I am not confident; whether he settled with him, or paid him, or not; I think he did.

X Q. 1975. Did any of those sample lamps have conductors of fibrous carbon slightly treated?

A. I do not know. Mr. Sawyer himself selected them from a barrel of lamps which was stored in the upper story of the building, No. 3 Mercer street, where I had my office.

X Q. 1976. Did any of them have looped or arch-shaped carbons?

A. I made the same answer.

X Q. 1977. Did the company ratify or approve Sawyer's selection?

A. No further action was taken on it.

X Q. 1978. Did you, or the company, know at the time what lamps he selected?

A. No, I don't think any of us did, except Mr. Sawyer.
1542 Mr. Sawyer also was permitted by the company to take for
his own use a considerable number of the lamps at the time
when we broke up at 94 Walker street.

X Q. 1979. Was the arrangement made by the Electro-Dynamic Light Co. with the Wallaces in writing?

A. The arrangement with the Wallaces was made by Mr. Sawyer alone, afterwards ratified by the company, and a license to them was reduced to writing, and I think executed by the company and Mr. Wallace, which was afterwards surrendered and cancelled, and lost or destroyed, at least I made a diligent search for it and could not find it.

X Q. 1980. Did that agreement ever get into the possession of the complainant so far as you know?

A. I do not know. I do not believe it did.

X Q. 1981. Did that license include the invention of the patent in suit in its terms, so far as you know?

A. I think it did, but I do not know. If it was covered it was under a general heading, covering all inventions owned by the Electro-Dynamic Light Company having reference to electric lighting and distribution of current of electricity, &c., &c., and not by specific reference.

X Q. 1982. Did the Electro-Dynamic Light Company or did you so far as you know, ever inform the Wallaces of the invention of the patent in suit?

A. I do not remember.

X Q. 1983. Who was president of the Electro-Dynamic Light Company at this time?

A. I was president during the negotiations and Mr. Thomas Wallace became president through the negotiations and entered upon his duties as such, and I became vice-president, and I remember that by a resolution of the company, I was directed to execute the license, by reason of Mr. Wallace being president and interested as one of the licensees.

X Q. 1984. I understand that after the arrangement with
1543 the Wallaces fell through and the license was cancelled, the
Eastern Electric Manufacturing Company which had been previously formed by Sawyer as a hostile company, acquired all the patents and inventions of the Electro-Dynamic Light Company, and after they had been so acquired, manufactured some lamps. Am I correct?

A. That is substantially correct. The license to the Messrs. Wallaces was surrendered by them through negotiations with the Electro-Dynamic Light Company just previous to and in contemplation of the sale of the patents to the Eastern Electric Manufacturing Company. That company made some lamps with which they made exhibits in Philadelphia, St. Louis, Chicago and Boston. I never saw them and don't know what they were or how many there were of them. I saw some lamps of their make in their new place in Fulton street. I think all this was done under the superintendence of Mr. Sawyer.

X Q. 1985. The patents afterwards became the property of the complainant?

A. Yes.

X Q. 1986. And the complainant has manufactured and sold incandescent lamps?

A. Yes, in large numbers.

Adjourned till Friday, 16th, 1887, at 10½ a. m.

1544 FRIDAY, *December* 16, 1887.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN proceeded:

X Q. 1897. Your agreement with Mr. Sawyer of May 11th refers to certain patents of his in which one James Flanagan is stated to have an interest. Please state whether, when you first went to work with Sawyer, you knew what his relations with Mr. Flanagan were or had been concerning his inventions, whether you ever learned of any agreement made between Sawyer and Flanagan and one Smith, and when you first saw that agreement.

Objected to as not cross-examination, incompetent, irrelevant and immaterial, and notice of motion is given to strike it out at the hearing, together with any answer the witness may make to the question.

A. When I first went with Mr. Sawyer I knew nothing of any agreement on his part with Mr. Flanagan, or any obligations on his part to anybody, further than that he told me that the patents which he showed me, and which are referred to in the agreement of May 11, 1878, had been assigned in part, I think three-fifths, to Mr. Flanagan, and he claimed that he had the right to and would redeem them and have them reassigned to him and to convey me $\frac{45}{100}$ths of the same provided I would go on and furnish money for experiments; that was the condition of things until some time after we went to work, when I learned that there was a written agreement between him and Flanagan; I asked him to show the agreement, and some time in May, 1878, as I think, he showed me the agreement, or what he said was a copy of it, very soon after we went to work at 43 Centre street; Mr. Flanagan was in there at our shop, and several times, I think twice or three times, perhaps more, 1545 and saw us at work, and I invited him to unite with us in the project, to which he replied that he would think of it; I asked him if he could not get other parties to come in, and unite with us himself; the lamps were shown to him at the time, lighted; he seemed very friendly, and in the course of the conversation, I think in reply to my suggestion to his coming in and getting other parties to unite, he used these words, "I'll think of it, and all events if I don't help you, I won't hurt you." About this time I became cognizant of a quarrel or disagreement that appeared to have occurred between Sawyer and Maxim and Schuyler, who were, I understood, in some way, associated with Flanagan; Sawyer was angry with them and good friends with Flanagan; after this and before hearing of the agreement between Sawyer and Flanagan, I requested Sawyer, because Flanagan did not unite with us, to get from Flanagan an account of the expenses which he said were to be paid in order to obtain a reassignment of the patent referred to in the agreement of May 11th; such an account was rendered by Mr. Flanagan; Mr. Flanagan and Mr. Sawyer were not agreed about the account—discussed it in my presence at 43 Centre street; I think this was some time in April, 1878; when I learned of a written agreement between Sawyer and Flanagan I supposed it to be between them alone; I asked Mr. Sawyer to give it to me to look at by reason of his disagreement with Mr. Flanagan about the account Flanagan had rendered; after some time, and I think in the month of May, 1878, I got view of the agreement, or a copy of it, or what purported to be a copy; up to the time and even after the rendering of the account by Flanagan to Sawyer, they were very friendly with each other, and at the close of the interview at which I asked Mr. Flanagan to unite with us in the project, they went away together in a cab.

X Q. 1988. Did Flanagan know of your agreement of March 19, with Sawyer, by which you were to pay for his experiments and get $\frac{45}{100}$ths interest in his patents?

1546 Same objection and notice.

A. I never told Mr. Flanagan the character or contents of any agreement that I had made with Mr. Sawyer, but he knew from me from the first time I saw him at 43 Centre street, very soon after we went to work, that I was interested in the operations there and must have known that I was paying the expenses.

X Q. 1989. Did you ever tell him you were paying the expenses?

Same objection and notice.

A. I told him what was tantamount to that in asking him to come in with us.

X Q. 1990. Did he ask you if you were paying the expenses?

Same objection and notice.

A. No, not to my recollection.

X Q. 1991. In asking him to come in with you did you explain to him that you were paying the expenses and were to get an interest in any of the inventions?

Same objection and notice.

A. I do not remember to have made any detailed explanations to him.

X Q. 1992. Do you remember giving him to understand that such was the fact?

Same objection and notice.

A. Most clearly that I was interested in what was going on.

X Q. 1993. Did you tell him how, or in what way you were interested?

Same objection and notice.

A. No, I did not.

X Q. 1994. Did Sawyer tell him, so far as you know?

Same objection and notice.

A. I do not know what Mr. Sawyer told him; I know that Mr. Flanagan knew, while we were at 43 Centre street, that Mr. 1547 Sawyer and I were interested in this matter, in this way; during the latter part of the time while we were there at 43 Centre street, Mr. Flanagan's brother, as I was told from him, Mr. John R. Flanagan, went to my uncle, Mr. A. P. Man, and sent him to me to caution me about Mr. Sawyer, that he was a bad man; my uncle conveyed this message to me.

X Q. 1995. When you came to read the Flanagan agreement, or what purported to be a copy of it, did it occur to you that, under that agreement, Flanagan could claim an interest in Mr. Sawyer's invention?

Same objection and notice.

A. It did occur to me that such a thing was possible as that Mr. Flanagan might make such a claim, under that agreement; I examined the instrument with that view, and took legal counsel upon it, and came to the conclusion that he could not sustain such a claim, as also did my counsel, Mr. A. P. Man.

X Q. 1996. Did you communicate with Mr. Flanagan and ask him if he intended to make such a claim?

Same objection and notice.

A. No, sir.

X Q. 1997. Did you speak to Sawyer on the subject?

Same objection and notice.

A. I think I did.

X Q. 1098. Did you take him to task for not having told you of this agreement when you were working together?

Same objection and notice.

A. I do not remember; I remember only that Mr. Sawyer always claimed that he was under no obligation under that agreement for any inventions he might make after he ceased to be paid under the agreement a certain stipulated sum, as wages or expenses, and that those payments had ceased before he came to work with me.

X Q. 1999. Did you ever make any effort to get Flanagan to release any claim he might have had on those inventions?

1548 Same objection and notice.

A. No, I never did, and he never made any claim.

X Q. 2000. Did you ever suggest to any one, or were you ever advised, that the taking out of the inventions in your joint names would protect your interest and cut off Flanagan?

Same objection and notice.

A. Not in that way.

X Q. 2001. In what way, then?

Same objection and notice.

A. That even if Mr. Flanagan should make any claims upon Mr. Sawyer he had no claim upon the joint inventions of Mr. Sawyer and myself, and the patents would and should be taken out in our joint names; I explained the whole subject-matter of what I had done to my uncle, Mr. A. P. Man, at the time I consulted with him with regard to the Flanagan agreement, and in that consultation he agreed with me in opinion, that Sawyer's and my joint inventions were certainly and unquestionably in no way effected by the so-called Flanagan agreement; but he also told me, at the same time, that neither were Mr. Sawyer's individual inventions made after he separated from and ceased to work for Mr. Flanagan, liable in any way to claim by Flanagan, in his opinion, which was the same opinion which I had myself formed.

X Q. 2002. Was the agreement of May 11th made after this consultation with your uncle?

Same objection and notice.

A. I cannot tell whether after or before.

X Q. 2003. In the discussion preceding this agreement with Mr. Sawyer, was the Flanagan agreement referred to in any way?

Same objection and notice.

A. I have said that I think that this agreement, or the copy, had
been handed to me by Mr. Sawyer before the agreement of
1549 May 11th; of this I am not sure; if it was so handed to me
before the 11th of May by Mr. Sawyer, the discussions of the
agreements between him and me were prior to the agreement of that
date.

X Q. 2004. Do you know whether Sawyer ever stated, in substance, that the agreement of May 11th and the taking out of the patents in the joint names of Sawyer and Man, was a subterfuge to get around any possible claim that Flanagan might make or have?

Same objection and notice.

A. No.

X Q. 2005. You have never heard that Sawyer so claimed or stated?

Same objection and notice.

A. No; I do not remember to have ever heard of that statement having been made by Mr. Sawyer, but it would not surprise me, considering the other false statements that he did make of which I heard and of which he himself told me that he had made, if I should hear that he had made such statement, or statements to that effect.

X Q. 2006. Did you ever hear of such a statement or claim as having been made by anybody?

Same objection and notice.

A. Yes; I think I have as coming from our opponents in the interference cases and suits in regard to our patents.

X Q. 2007. But never as coming from Sawyer, Flanagan or Schuyler?

Same objection and notice.

A. No; I don't think I have in regard to that agreement.

X Q. 2008. You do know that Sawyer asserted that the alleged Sawyer-Man inventions were the sole inventions of himself?

Same objection and notice.

A. I heard that Mr. Sawyer had made such statements; he told
me more than once that he had done so; several times he
1550 told me so; he told me at the same times that he was sorry,
and begged my pardon for having done so, and stated that
he was drunk when he did it, and that he was influenced by other
parties to do it, and tried to make excuses for it.

Defendant's counsel offer in evidence agreement between William E. Sawyer and James Flanagan, dated January 2, 1877, and the same is marked "Defendant's Exhibit Flanagan Agreement, December 16, 1887;" also accounts of Flanagan's disbursements on behalf of Sawyer's experiments, December 16, 1887.

Exhibits objected to as incompetent, irrelevant and immaterial and not cross-examination.

X Q. 2009. What explanation have you to offer of the fact that no application for a patent covering the invention in suit was made until nearly two years after the time you say the invention was made?

A. First, that our counsel, Amos Broadnax, doubted the patentability of the invention, and although applied to in October, 1878, to make application for patents on the invention, postponed it until first he could go and see it and ascertain more about the matter, and afterwards by reason, as he told me, of press of business, until Mr. Sawyer and I quarreled, and after that I could not get him to unite in applications for patents, and because I thought we were in time to make the application at any time until I heard that other parties were liable to make application.

X Q. 2010. Now, as to the first reason given, you say that Mr. Broadnax was applied to, to prepare an application to cover the invention of the patent in suit in October, 1878, who saw Mr. Broadnax on this subject?

A. Both Mr. Sawyer and myself; I know I did.

X Q. 2011. What did you tell him the invention was?

A. A loop carbon made of paper or wood.

X Q. 2012. Did he tell you he did not consider the invention patentable?

1551 A. No; he told me he considered it doubtful, as he looked upon it; that it was simply charcoal which had been used in incandescent lighting before.

X Q. 2013. Did he advise you not to apply for a patent?

A. No; on the contrary, I saw him several times in regard to it, and at last got him to go and see it; he did not then, after seeing it, as I remember, change his mind in regard to the matter; at least, he postponed it.

X Q. 2014. Did he advise you to apply for a patent on it?

A. According to the best of my recollection, he told me that there was plenty of time, and that he had his hands full with another work; I do not remember his advising me to apply for it, but only to postpone it.

X Q. 2015. Why to postpone it; to suit his convenience?

A. Yes; to suit his convenience and to allow him to go on with other pressing work of the company.

X Q. 2016. Had you ever mentioned the invention to him before October, 1878?

A. I do not know whether I had or not; I don't remember to have done so; I think the first was shortly before the making of an assignment by Mr. Sawyer and me to the Electro-Dynamic Light Company, of carbons for electric lamps, and treatment of carbons for electric lamps, or at the time of making of that assignment;

Mr. Sawyer and I were both present at that time; I think that I had talked with Mr. Broadnax somewhat before the execution of this assignment and of our inventions and got Mr. Sawyer to go to his office with reference to making applications for the patents and assigning them to the company, but whether I had spoken to Mr. Broadnax about this particular invention before the making of that assignment I cannot remember; it was talked over at the time of the making of that assignment.

1552 X Q. 2017. Is it then the fact that the first time you remember to have spoken of this invention to Mr. Broadnax was about the time of the assignment to the Electro-Dynamic Light Co., dated the 14th of October, 1878?

A. Yes.

X Q. 2018. You say he expressed doubt as to its patentability; did you discuss the question of its patentability with him and seek to remove those doubts?

A. Yes, somewhat; I think to about the extent of saying to him that I thought it was a good thing and new in the manner in which we use it, that we ought to be able to get patents for it.

X Q. 2019. What did he say in response to this?

A. I do not recollect further than as I have said.

X Q. 2020. Were his doubts removed by what you said?

A. I don't know; I can't recollect in terms of sufficient accuracy to repeat the conversation between us. I know I urged him to go and see it.

X Q. 2021. Do you recollect the fact whether his doubts were removed as to the patentability of the invention or whether he still adhered to them?

A. I don't really know or recollect.

X Q. 2022. In your 2018th answer you say you stated to him that you thought it was new in the manner in which we used it; did you explain to him how you used it?

A. I think so.

X Q. 2023. How did you tell him that you used it?

A. That we cut it out and shaped it, and carbonized it after we cut it out, and that I thought that the loop or arch was a new form for incandescent carbons.

X Q. 2024. Did he combat that idea or agree to it?

A. I don't know; don't remember.

X Q. 2025. Did you tell him the importance you attributed to the invention, and how great you regarded its value?

A. I don't remember.

1553 X Q. 2026. Did you instruct him to apply for patents for the invention irrespective of what his opinion as to its patentability might be?

A. I asked him to do so.

X Q. 2027. Did he promise to?

A. I don't know further than that he promised to consider it and see what was best to be done about it.

X Q. 2028. Consider what, whether he would apply for a patent for it, or whether it was patentable?

A. Really I have related the substance of what took place between Mr. Broadnax and myself in regard to it. I can only give general ideas in regard to it. The impression in my mind is that he told me that he would consider how he would apply for a patent for it, what kind of a patent he could get for it, or a part of it.

X Q. 2029. Did you see him afterwards on this subject and ask him to what conclusion he had come in regard to it?

A. Yes, I saw him almost every week, and I frequently talked with him on this subject after he had been up and seen the thing at 94 Walker street. I think the general conclusion was that the invention, or some part of it, was patentable, particularly the loop form of the carbon, but that it could wait until he got other things out of hand which he was at work at for the company.

X Q. 2030. How long do you suppose it would have taken a lawyer of Mr. Broadnax's skill in these matters to have drawn up an application for a patent?

A. I don't know. I suppose it would depend upon the difficulty of the subject, and his information on the subject in regard to which he was requested to prepare the application.

X Q. 2031. Did Mr. Broadnax ever prepare an application?

A. Not to my knowledge; he assisted or advised some-
1554 what at the time when the application was finally filed by
Mr. Baldwin.

X Q. 2032. The specifications of several of your patents were drawn up by Mr. Sawyer, were they not?

A. Yes, our first patents before we left 43 Centre street.

X Q. 2033. He was familiar with the drawing up of specifications was he not, and able to draw them?

A. I don't know how familiar he was; he did draw up specifications for these patents I have mentioned.

X Q. 2034. Did he ever draw up a specification on the invention in controversy?

A. Yes, I think so.

X Q. 2035. When?

A. When the application was finally filed.

X Q. 2036. Did you ever draw up a specification on the invention in controversy?

A. Yes.

X Q. 2037. When?

A. I drew up several.

X Q. 2038. When?

A. It was in the nature of a specification; in the fall of 1878 and in the winter following.

X Q. 2039. What was your object in drawing these up, and what did you do with them?

A. My object was to clear up my own mind as to what we had a right to patent, and to get Mr. Sawyer's ideas in regard to it. I don't know what became of them.

X Q. 2040. Did you regard Mr. Broadnax as neglecting the matter of filing an application on this invention?

A. No.

X Q. 2041. If either you or Mr. Sawyer or the company had especially desired him to draw an application on this invention 1555 and instructed him to do so, have you any doubts as to whether he would have obeyed those instructions?

A. I suppose Mr. Broadnax would if he had time have obeyed any positive instructions that were given to him by me as president of the company, or by directions of the board, but we were following his counsel and did not give positive instructions, but only general ones, and this was not the only matter by a great many where patents were not taken out, in which Mr. Broadnax was advised with, and in which we desired him to obtain patents.

X Q. 2042. Had you stated to Mr. Broadnax that you considered this a very important invention, and that you wanted him to determine the question of its patentability, and apply for a patent, do you not think he would have found time to have done as you wished?

A. I do not know that he would during the limited time after he had seen the thing and before Mr. Sawyer refused to sign any more applications for patents for the company, unless he had been told that it was a matter of great haste, requiring positive and immediate attention, which he was not told in regard to this matter.

X Q. 2043. Then I understand the fact to be that in October, 1878, you mentioned to Mr. Broadnax the use of fibrous material as the incandescent conductor, and use of an arch form of incandescent conductor, and told him how you made it, that Mr. Broadnax considered that it was very doubtful whether there was anything patentable in the use of paper or fibrous material as an incandescent conductor, that several interviews afterwards were had with Mr. Broadnax on this subject, that his doubts as to the patentability of paper or fibrous material was not removed, but that he considered the form of conductor might be patentable and the method of making it, that the matter was thus postponed, and that he did nothing in the way of preparing an application except to go and see the lamp with such carbons in it?

1556 A. Yes, such was about the consideration that the subject received as I remember, and all the consideration except discussions in regard to patentability and general requests when he could, to take the subject up and see what he could do with it, to do so.

X Q. 2044. Do you understand that we have been referring to a period between October, 1878, and March, 1879?

A. Yes, so far as Mr. Broadnax is concerned and his intercourse with Sawyer.

Adjourned till Monday, the 19th inst., at 10.30 a. m.

MONDAY, *December* 19, 1887.

Met. Present counsel as before, and the cross-examination proceeded.

X Q. 2045. In your 2009 answer you give as an additional reason for the delay or neglect to apply for a patent, that after you and

Mr. Sawyer quarreled he refused to sign applications for patents for the Electro-Dynamic Light Company.

A. Yes.

X Q. 2046. When did the quarrel occur?

A. I had no personal quarrel with Mr. Sawyer, I never would quarrel with him. It perhaps might better be characterized as a disagreement and ill-feeling on his part toward me, arising and growing out of his bad habits, and culminated some time in January, 1879, when or soon after Mr. Lawrence Myers ceased to go to the shop. From this time forward, and even afterwards, with occasional intervals when he would comply with some of my requests, but not with many. At the time I have mentioned in January I told him unless he could change his habits and give better
1557 attention to the business that the work must stop, or that his supervision must cease.

X Q. 2047. What efforts were ever made so far as you know to get Mr. Sawyer to join in an application for a patent on the invention in controversy?

A. I asked him to do so before we broke up at 94 Walker street several times. I think Mr. Broadnax asked him to unite in applications, and he declined absolutely to execute any papers that would benefit the Electro-Dynamic Light Company.

X Q. 2048. Do you mean to be understood that you asked him to unite in an application for this specific invention?

A. Yes, I mean that I asked him to unite in applications for all the things that he and I had worked together upon and I talked over the things with him. I also asked him to execute applications, and assign them to the company for all that he considered his sole inventions. I do not remember specifically the different things that I spoke to him about. They were all the inventions in which I had worked with him, and I have no doubt that this was spoken of with them, but I have no distinct recollection of this as separate from any of the others.

X Q. 2049. No application for the patent was ever drawn up, and he asked to execute it, was there?

A. My recollection is that a description and provisional specification was drawn up by Mr. Sawyer and myself I should think separately; and that Mr. Sawyer's paper was handed to Mr. Broadnax for him to prepare the application. I should think too no formally prepared application for a patent was presented to Mr. Sawyer for execution, still I do not know in regard to that and several formal applications were prepared and sent to him which he refused to execute. This may have been among them, but I don't know; my impression is that it was not.

1558 X Q. 2050. When was this "provisional" specification prepared, and what do you mean by "provisional"?

A. I mean by that, simply such a description and such an indication, in regard to what claims might be made as a client would ordinarily furnish his attorney in regard to an application for a patent. If it was furnished to Mr. Broadnax, it was done prior to the 1st day of January, 1879, or during the first days of that January.

X Q. 2051. Did Mr. Broadnax, so far as you know, ever prepare a formal application for a patent on this invention?

A. I do not know that he did, until the final application in which he participat*ing* by advising me in regard to it.

X Q. 2052. Was he ever formally instructed by you or the company to prepare an application?

A. He was only formally employed by the company and requested to prepare applications generally, never as I know formally instructed to prepare applications for any particular patent, though I do not say that he was not.

X Q. 2053. Did the company ever formally request Mr. Sawyer to execute an application for the patent in controversy?

A. Through me, yes; verbally, a good many times.

X Q. 2054. Who in the company so asked you to request Mr. Sawyer?

A. I was president of the company and chairman of its executive committee, and entrusted and charged with these matters, and I did it of my own motion in the discharge of my duty, and at several of the board meetings I was requested to get Mr. Sawyer to make or unite with me in making applications for patents for all our inventions.

X Q. 2055. I am only interested in knowing concerning the invention in controversy. Do you remember ever having been requested by any person in the company, to ask Mr. Sawyer to join
you in an application for a patent: for the invention in
1559 controversy, I mean in regard to this specific invention?

A. I do not remember this as distinguished from any other.

X Q. 2056. Do you remember that this was discussed with the others, or are you only inferring in regard to it?

A. Yes, I remember this invention being talked about at the board meetings.

X Q. 2057. Who now living was present at those meetings and ought to remember of this invention being talked of?

A. I don't know who would remember; I have not talked with them about it.

X Q. 2058. Who was present at these discussions?

A. I cannot recollect only that a quorum of the board was present.

X Q. 2059. Was any formal resolutions passed or any record in the books made that would show that this invention was discussed or any action taken in regard to it?

A. I think not, but I do not recollect.

X Q. 2060. So far as you know, prior to the appearance of Mr. Cheever on the scene, were Mr. Broadnax's doubts as to the patentability of fibrous material ever removed?

A. I do not know.

X Q. 2061. Did you ever inform any person in the company of the value you attributed to fibrous material, so that a determined effort might be made to get Mr. Sawyer to file an application or get one prepared?

A. I do not remember.

X Q. 2062. Now, between January, 1879, and January, 1880, Sawyer did execute assignments of patents to the company?

A. Yes; of things or inventions already patented, or for which applications had been filed, but not, I think, of any others.

1560 X Q. 2063. Did he not also sign applications for patents?

A. I don't recollect; he may have done so.

X Q. 2064. During the year 1879 was not Sawyer in the pay of the Electro-Dynamic Light Co.?

A. Part of the time.

X Q. 2065. Do you include the period he was with Wallace, in your answer?

A. Mr. Sawyer was paid for the service with Wallace in advance, in the manner I have stated, at the time he made the arrangement with Mr. Wallace in the spring of 1879; he was not under the control or properly an employee of the company, except to render service at Wallace's place for which he had been paid.

X Q. 2066. How was Sawyer induced to sign the assignments and papers in 1879?

A. I do not recollect the circumstances fully in regard to the thing; I only recollect that after a great deal of work I got him to sign in February—I think it was 1879—a kind of confirmation assignment, if my recollection serves me right; it was upon an understanding that if Sawyer could get parties to pay the Electro-Dynamic Light Co. for all the patents and inventions they would be assigned to the parties he should designate.

X Q. 2067. There appears to have been three assignments made by Mr. Sawyer to the Electro-Dynamic Light Co. in 1879, one dated July 31, 1879, on a patent allowed upon an application of his, filed April 23, 1879, for an improvement in electric lamps—two; an assignment, dated February 3, 1879, of letters patent to Wm. E. Sawyer, No. 210,151, for an electric meter; letters patent 210,152 for switch; letters patent 210,809 for an electric lamp; letters patent 211,262, for carbon; three, a general release, dated May 21, 1879, to the company of all claims, in consid*sid*eration of forty-nine thousand, alleged to have been paid; four, an assignment, dated
1561 July 30, 1879, an application for letters patent, filed April 23, 1879; it thus appears that in July, February and May, 1879, Sawyer executed two assignments and one general release to the company. How did the company secure the execution of these papers?

A. I have already explained in regard to the assignment in February, which I got as a confirmation assignment of patents already then issued, and application already then filed, not of any new applications or inventions for which applications had not been made; that it was done, according to the best of my recollection, by Sawyer after a great deal of quibbling and bother and hesitation, and striking out of everything but those matters, upon a kind of understanding that if Sawyer could find parties to pay the Electro-Dynamic Light Co. for all the patents and inventions what that company owned, they would be assigned to such parties by the company, it was under such an understanding, modified to conform to the agreement made with Wallace, that that agreement was negotiated by Sawyer; the release executed by Sawyer to the company was required by the company as part of the arrangement in closing with Wallace; the assignment of July, 1879, was an assignment of a feeder lamp, the invention of Sawyer, as he claimed, which was made part of or to come under the license to the Wallaces, and Mr. Broadnax took charge of the application and obtained the final assignment in July from Sawyer, in confirmation of previous assignments, and the understanding at the time of the agreement with Wallace.

X Q. 2068. When the application for the patent in suit was filed, its preparation seems to have been the subject of some discussion; why was no mention made of what the advantages of fibrous carbon or paper were?

Objected to as utterly immaterial, and as it is of no sort of importance whether the specification states the advantages of the invention or not.

A. If such is the fact I do not know or recollect.

1562 X Q. 2069. If you had found fibrous or paper carbon superior to non-fibrous carbon, and if, as you say, preferred it to the incandescent conductor of an electric lamp, why did you not state that in the specification?

Same objection, and further that it was a common practice among the examiners of the Patent Office, to insist that everything in the specification going to show the advantages of the invention should be omitted.

A. I don't know or recollect further than I have stated the circumstances under which the application was made, and I don't know whether they had anything to do with it or not.

X Q. 2070. You have said that to get the best conductor from fibrous material, a certain arrangement of fibres was advantageous: why was not that fact mentioned?

A. I do not know why it was not mentioned or why it should be mentioned.

X Q. 2071. You have stated that it was easier and better to cut the material to size and shape, and carbonize it afterwards, rather than to cut it from a block of the material after carbonization; why was that not mentioned in the specification?

A. I do not know that it was not mentioned in the application as sent to Mr. Sawyer for execution, and I do not know that it is not included in the application as filed, and if not included I do not know why it was omitted.

X Q. 2072. You do not remember why the application as filed did not state the advantages of fibrous material over a mineral carbon. Can you tell me why the patent as issued stated the advantages?

A. I suppose from the desire of the solicitor or myself, or both, if it does so state.

X Q. 2073. Please do "not suppose," but tell me what the fact is, if you know?

A. I only know that Mr. Broadnax, the solicitor, and I
1563 consulted together and made the application for the patent
when it was made, and Mr. Sawyer, I think consulted with Mr. Broadnax in regard to it, and that the patent was allowed and issued as it was issued; that is all I know about it.

X Q. 2074. Do you remember consulting and advising with Mr. Broadnax as to whether the specification should be made to state the advantages of fibrous over non-fibrous material?

Objected to as being a misstatement of facts leading to the inference that the specifications does not state the superiority of the invention over other carbons for incandescent lighting.

A. No, I do not remember anything but the fact of the consultation with Mr. Broadnax at this moment; if any particular consultation or conversation, of which there were a number, were called to my attention, I might be able to remember some of the details of these consultations, but I do not now.

X Q. 2075. You do not then remember having discussed with Mr. Broadnax whether the specification should be made to state the advantages of fibrous over non-fibrous material?

A. I do not.

X Q. 2076. You have been unable to state why the original specification did not state that the material was to be cut to size before carbonization; can you tell me why it is that the patent as issued states that it is to be done?

Objected to as a repetition; the question has been already asked and answered.

A. I have not intended to state that I knew that the application as prepared before modification by Mr. Sawyer, or as finally filed, does not or did not contain or imply that the carbon was cut to size or shape before carbonization, only that it did not contain or imply that; I did not know or recollect why; I now say that if the patent as issued contains that statement I suppose it contains
1564 it in accordance with the ideas of Mr. Sawyer and myself
and Mr. Broadnax, as the right thing to be there, and in accordance with the facts of the invention; I know no other reasons, or at least, no others occur to me.

X Q. 2077. Please do not "suppose," but tell me if you know why the patent as issued was made to contain this statement?

A. I have stated all that I know. I was not the attorney or solicitor. I assume that if anything was not put in the patents or applications, it was because the solicitor thought there was enough there, or from some exigencies arising in the Patent Office during the interference, and that *that* everything — was put in the specifications and patents was put there in accordance with the facts given to the solicitor and proved in the interference. I don't know personally further than I can know by the correspondence of the specifications and the patents with the facts given by the inventors.

All that the witness has assumed is moved to be stricken out.

X Q. 2078. Were you aware at the time that the 1st, 2d and 4th claims of your patent as filed were rejected as not containing patentable matter?

A. I don't know.

X Q. 2079. Were you aware that when the interference was declared with Edison's application that the 1st, 2d and 3d claims of your application as filed were rejected?

A. I don't think I knew it; I don't know.

X Q. 2080. After the decision of the interference did you read the various amendments that were filed prior to their being filed?

A. I don't know; I don't think I did; I read some proposed amendments at some time, but what they were I don't know; I think the proposed amendments were to claims only; they may have been to the specification also.

1565 X Q. 2081. It appears from the file-wrapper of the application for the patent in suit that the 4th claim of the application as originally filed

"An incandescent arc made of carbonized fibrous or textile material"

was on the 9th day of January, 1880, rejected by the office—that a new specification was filed May 17, 1880, in which the first claim was

"An incandescent arc for an electric lamp of carbonized fibrous or textile material and of arch or horseshoe shape, substantially as hereinbefore set forth."

That on May 20th that claim was rejected, that on December 4th, 1884, Mr. Broadnax amended the application by inserting the issue of the interference as a claim, and requested that the 1st, 2d and 3d amended claims filed May 17th

"Having been once rejected by the primary examiner, are now respectfully submitted for reconsideration."

The official letter of the examiner in reply and under date of February 19th, 1885, holds that claims 2 and 3 are fully anticipated, but makes no mention of claim 1 which at that time stood rejected. On February 19th, Mr. Broadnax amended the application of May, 1880, substituting in the first claim for the word "arc" the word "conductor" and asking that the second and third claims be stricken out. Were you aware of these proceedings in the office?

Objected to as immaterial, incompetent, and not cross-examination.

A. I do not know and have no means of verifying the accuracy of your statement; I was aware of some things being done as they went on; what I cannot recollect.

X Q. 2082. On February 20th, 1885, notice was sent by the Patent Office that your case was ready for issue, but was suspended 1566 until March 2, in view of a possible interference with another pending application; did your counsel advise you of this notice?

A. I do not know, nor do I know that such was the fact. I don't remember.

X Q. 2083. Did Mr. Broadnax ever tell you after the decision of the interference with Edison that there was a possibility of an interference with some one else?

Ans. I don't remember whether he did or not.

X Q. 2084. Never remember to have heard anything about a threatened interference?

A. It seems to me that at some time or other I heard something about an interference other than that with Edison having been threatened in that case, whether, after the issue of the patent, or during the progress of the case, or who I heard it from, or what its character was, or what it applied to, I cannot recollect.

X Q. 2085. Now, on February 28th, a long amendment was filed, which amendment I now show you; were you aware of the filing of that amendment, or consulted at the time in regard to it?

A. I am unable to identify the paper you show me, from recollection, as a copy of anything that I saw; much of what is contained in the paper seems familiar to me; whether I was cognizant of its filing before or at the time it was filed I cannot say; I do not recollect.

X Q. 2086. I show you what purports to be a copy of an amendment filed March 13th, were you cognizant of, or consulted with regard to the preparation of that amendment?

A. My answer to that question is in the same words as my last answer.

X Q. 2087. I understand this Mr. Sawyer died in the latter part of 1882; so far as you know were the Patent Office in the conduct of this application ever advised of his death?

A. I don't know.

1567 X Q. 2088. Do you know whether letters of administration were ever taken out on his estate?

A. I do not.

Adjourned till January 5th, 1888, at 1 p. m.

NEW YORK, *January 5th*, 1888.

Met and adjourned subject to agreement of counsel.

NEW YORK, *April 26th*, 1888.

Present, counsel as before, and the cross-examination of MR. MAN proceeded as follows:

X Q. 2089. On pages 403 and 401 of the printed record reference was made to the newspaper publication of certain letters of Mr. Sawyer, did you ever contradict the statement of those letters in print?

A. I do not remember to have ever published anything, and do not think I did.

X Q. 2090. Are you familiar with what is known as the "squirt" or "syringe" process of making hard carbon?

A. I have heard it described and have seen it in operation in the process of making pencils and pencil points of plumbago and similar substances.

X Q. 2091. Could pencils of carbon be made by such process from hard carbon as cheaply as pencils of carbon could be made by cutting fibrous material to the desired size and carbonizing it?

Objected to on the ground that the witness has stated that he was not practically familiar with the process.

A. I don't know, undoubtedly pencils of some quality, good or
bad, could be made cheaply by the syringe process. I am unable
1568 to state that a good pencil of hard carbon could be made by
that process, of sufficient tenuity as cheaply as the carbon
could be made by cutting fibrous material to the desired size, or selecting it of the desired size and carbonizing it, as I think they would require further manipulation, sizing and cutting to lengths and treatment after their first production from the syringe.

X Q. 2092. Were you familiar with this squirting process in 1878 and 1879?

A. I think so, as much so as I am now.

X Q. 2093. Did you ever try it in the manufacture of carbon?

A. We tried pencils of carbon so produced.

X Q. 2094. Did you ever make them yourselves?

A. No, not to my present recollection, but I am not quite certain.

X Q. 2095. Who made them for you?

A. I think it was the Eagle Pencil Co., but I cannot state positively.

X Q. 2096. Do you remember what license fee Wallace was to pay the Electro-Dynamic Light Co. on each lamp?

A. I do not remember now, but by reference to the testimony on some of these previous cases, I see a resolution of the Electro-Dynamic Light Company's trustee fixing it at three dollars per lamp. I assume this was correct and believe it to be so.

X Q. 2097. What did you estimate one of your lamps would cost to manufacture?

A. I don't know. We hoped to be able to make the lamps as cheaply as a quarter of a dollar apiece, but we never did build any so cheaply as that that were permanent lamps, nor nothing near it.

X Q. 2098. In several parts of your testimony you speak of your "workshops." By these I understand you to refer to your shops at 43 Centre street, Howard and Centre and Walker and Elm streets. Is that right?

1569 A. It is.

X Q. 2099. In the "Scientific American" of Dec. 7, 1878, is printed an article headed "The Sawyer-Man electric lamp." Do you know how such article came to be published?

A. Yes; a gentleman from that paper came to the office, or workshops, 94 Walker street, and got the information, and as I unstood, wrote, and the paper published that article.

X Q. 3000. Got it from whom?

A. From Mr. Sawyer and myself. We did not procure or pay for the publication, but consented to it.

X Q. 3001. In the Weston-Sawyer-Man interference the following newspapers containing reference to the Sawyer-Man, and Sawyer lamp, were offered in evidence by your counsel: The Journal of Commerce, N. Y., Oct. 30, 1878; Commercial Advertiser, N. Y., Oct. 30, 1878; Evening Post, N. Y., Oct. 30, 1878; Tribune, N. Y., Oct. 30, 1878; The World, N. Y., Oct. 30, 1878; Philadelphia Record, March 25, 1880; Boston Post, March 17, 1881; Beverly Banner, Nov. 13, 1880; Public Ledger (Philadelphia), Oct. 28, 1880; Boston Morning Journal, March 17, 1881, same paper of March 18, 1884; Daily Evening Traveler, March 17, 1881. Do you know how the several articles referred to came to be printed?

A. I only know in regard to the articles in the New York papers of October 30, 1878. As to those articles, I have to say that previous to that time we were exhibiting the electric light at No. 94 Walker street, and the reporters were continually running there and asking about it and wanting to publish something about it. A day or two previous to the 30th of October, to avoid their running there one after the other, they were all invited, I think, by Mr. Sawyer, to come together and see the lamps, and these articles of October 30th were the result, if I recollect rightly, of that
1570 exhibition made to the reporters. We did not procure or
pay for the publication, but the reporters made their own reports and published what they liked about it.

X Q. 3002. You are the same Albon Man that testified in the Sawyer-Man-Keith, Sawyer-Man-Maxim and Sawyer-Man-Weston interferences, and the William E. Sawyer referred to in those interferences, and who testified therein, was your co-inventor, William E. Sawyer?

A. Yes.

Defendant's counsel offer in evidence the following:

1. Interference record and testimony, Sawyer-Man-Keith interference, and the same is marked Defendant's Exhibit Sawyer-Man-Keith Record, April 26, 1888.
2. Interference record, Sawyer-Man-Maxim interference, and the same is marked Defendant's Exhibit Sawyer-Man-*Keith* Record, April 26, 1888.
3. Interference record, Sawyer-Man-Weston interference, and the same is marked Defendant's Exhibit Sawyer-Man-Weston Record, April 26, 1888.

Cross-examination closed.

Adjourned subject to agreement of counsel.

1571 New York, *May* 29, 1888.

Met pursuant to agreement of counsel.

Counsel for the respective parties present as before.

Redirect Examination of Albon Man.

R. D. Q. 3003. In response to question 10 of your examination-in-chief you say you do not recollect of having used cane in making your incandescent conductors in the spring of 1878. Please to state what you recollect as to the use of cane for that purpose in the fall of 1878.

A. In the fall of 1878 I obtained from Crooks' establishment in Fulton street (the same man who now has a sporting-material store, I think, on the corner of Gold street and Fulton) a great variety of woods, and among others, cane, such as so-called bamboo fish poles are made of. I took them to our workshop, corner of Elm and Walker streets, and gave them to Mr. Myers to be carbonized and tried for the conductors of electric lamps. I think they were all carbonized and tried, but I have no recollection of conductors made from this cane as distinguished from the other woods that we used.

R. D. Q. 3004. Please to produce, if you can, specimens of endogenous woods having interlacing fibres such as you carbonized in the spring of 1878, as you have stated, for your incandescent conductors.

A. I produce a specimen of the wood of the Grugru palm which has such interlacing fibres, although not a good specimen of the interlacing fibres of that wood. Whether the wood we used was of this kind or not, I do not know, but it was with more interlacing fibres than this, and similar in appearance, but more dense. I also produce a specimen of so-called mangrove, a wood growing in the West Indies and in the Island of Bermuda, with interlacing
1572 fibres. I think this wood is properly guaiacum, which is commonly called, together with other woods of similar character, growing in the same localities, lignum-vitæ, and is known in the neighborhood of its growth as mangrove. We used lignum-vitæ wood, carbonizing and making conductors from it, in the spring of 1878. From investigation of the growth of this wood, I am convinced that it is both an endogenous and an exogenous wood; exogenous in the main, but endogenous in the filling up of the aerial roots which it puts forth from its branches, and which become filled up by an endogenous growth, to become new bodies for the trees and afterwards take an exogenous growth. It is a good specimen of interlacing fibre.

R. D. Q. 3005. These woods, as I understand you, you carbonized, among others, in the spring of 1878, for the purpose of ascertaining whether or not they would make satisfactory incandescent conductors for your electric lamp?

A. Yes.

R. D. Q. 3006. Did you carry the experiments far enough to ascertain whether or not such woods would make satisfactory incandescent conductors. I am referring now to the woods having the interlacing fibres, and if so please to state what the result of your experiments was.

A. Yes, we made straight pencil conductors of these kinds of woods, cut to size and then carbonized; which were good conductors, but found no corresponding advantage from the interlacing fibre over the straight fibre to compensate for the greater difficulty of working out the pencils from the inlacing fibre wood.

R. D. Q. 3007. These specimens which you have produced, are they part of the identical interlacing fibre wood used by you in the spring of 1878?

A. No; they are only similar woods.

The specimen of woods are offered in evidence and *re-*
1573 marked respectively "Complainant's Exhibits 'Grugru
Palm' and 'Mangrove,' produced by Albon Man, May 29,
1888."

R. D. Q. 3008. What, if anything, do you know of paper made of bamboo or cane fibre?

A. I have seen such paper and have seen the process of manufacturing or separating the fibre for the paper stock. It was at one time quite extensively conducted in South Brooklyn and I saw it there.

R. D. Q. 3009. Is it an article now or was it then an article of well-known manufacture in the paper trade?

A. It was at one time and I do not know but it is now, of domestic manufacture, and I think it is also imported from China and Japan.

R. D. Q. 3010. You have stated upon your cross-examination as well as upon your examination-in-chief that in the fall of 1878, and in the winter of 1879, you and Mr. Sawyer had reduced your lamp to a good practical operative condition, and that the Electro Dynamic Light Company had by that time taken measures to have the lamps manufactured and put in public use on a commercial scale. Now please to state in a connected way why the Electro Dynamic Light Company did not proceed with the manufacture and introduction of these lamps into public use, and state generally what efforts were made and what was done toward the manufacture and introduction of the lamp by that company and its successors?

A. After we had got the lamp and other apparatus in a substantially practical shape in the fall of 1878, the company decided to go on to the manufacture and introduction of the lamps into use. Mr. Sawyer was one of the inventors, and he and I were the only persons understanding the work in all its details and nicety. I was absorbed in business and Mr. Sawyer was the superintendent. His habits of inebriation and dissipation were such after this determination was reached by the company as to interfere with the
work more and more, that the last of March or first of April
1574 1879, the company decided to stop work under Mr. Sawyer's
superintendence. In the meantime Mr. E. L. Myers had
become conversant with the details of the work and an arrangement was made by which the Messrs. Wallace, of Ansonia, who were largely interested and had been for a long time in electrical development, to go on with the work and manufacture of the lamps

and other apparatus, and put them into use under a royalty to the company of so much per lamp for each lighting plant they should establish. Mr. Myers went with them, and I think Mr. Sharp, a skilful workman who had been in our employ. Mr. Sawyer was hired and paid by the Electro Dynamic Co. or its stockholders, to also go to Ansonia and give his time and attention and the benefit of his knowledge, for some months to the work. Mr. Thomas Wallace became president of the Electro Dynamic Co., and the work was commenced. Mr. Sawyer's inebriate habits, immorality and dissipation so interfered with the work and disgusted the Messrs. Wallace that they would have nothing to do with him, he left and as soon as his term of service, for which he had been paid, expired, or perhaps before he came to the company and requested and demanded a personal license to himself for our inventions, although an exclusive license had before then been given to the Messrs. Wallace. This the company refused and Mr. Sawyer went off and went to work to organize a rival company. Mr. E. L. Myers about the time Mr. Sawyer left was taken sick and went to his home in Plattsburgh, New York, where he lingered along for awhile and died. There was no one but he (Myers), Mr. Sawyer and I who understood the details of the work. During his (Myers') sickness it was thought best by the Messrs. Wallace and the company that the work should be suspended until he recovered and was able to take it up. My business was such that I could not give attention to it personally, and Mr. Sawyer was hostile. After Mr. Myers'
1575 death, there being no one to conduct our work, Mr. Sawyer's new company, the Eastern Electric Manufacturing Co., having been in the meantime organized, it was thought best that the two companies should be in harmony, and as a result the patents were assigned to the Eastern Electric Manufacturing Company, which agreed to go on with the manufacture and introduction of the lamps into use. They did go on to manufacture some lamps, and exhibit them, and make commercial arrangements for their introduction into use. Mr. Sawyer quarrelled with them continually, and his habits were very bad, and finally that company sold out to the Consolidated Electric Light Company, which immediately went on with the manufacture of the lamps and other apparatus, and their introduction commercially, and is engaged in that work now upon a large scale.

R. D. Q. 3011. You have stated upon your cross-examination that you and Mr. Sawyer frequently made your incandescent conductors of fibrous or textile material without treating them electrically after carbonization, and used such conductors experimentally in your lamps. To what extent did you practice such experimental work, and what did you prove by it as to the ;practical sufficiency of such conductors?

A. In making the conductors of fibrous carbon from different substances and frequently in making different batches of fibrous carbon conductors from the same substances, we set them up in our lamps and ran them for the purpose of testing the quality of the carbon without treating them electrically. This was our method of

testing the conductors. Each lamp was marked on a tag or label attached to it, and a record entered of its performance, usually on this label. A considerable number of these lamps proved to be good lamps. The conductors lasted well and were run for lighting our shops, and for exhibition, until the conductors gave out. Most of them gave out soon, but some, as I have said, proved to
1576 be good conductors, without treatment. But of the same
conductors treated, nearly all, instead of a few, proved good. We therefore adopted the treatment as a rule, as an improvement upon the conductors, I mean the electrical treatment patented by Sawyer & Man, by patent No. 211,262, or some of its modifications.

R. D. Q. 3012. Do you wish to be understood as saying that by these experiments you satisfied yourselves that good illuminating conductors for incandescent electric lamps could be made of the fibrous material experimented upon, or used by you without treating them electrically as described by the patent referred to?

Objected to as incompetent and irrelevant, and calling for a conclusion of law, and not for any fact.

A. Yes, without adding to them any deposit carbon and leaving them purely fibrous carbons.

R. D. Q. 3013. But you considered the carbons, as I understand you, to be improved by the electrical treatment, and you therefore adopted the treatment of the carbons as a general practice?

A. Yes.

R. D. Q. 3014. What did you mean by your answer to cross-question 310, where you say that you do not think you were diligent in applying for your patents?

A. I do not think we applied for them as soon as we might have done. We delayed for various causes our applications, but we always made them within the time prescribed by the law, two years.

R. D. Q. 3015. This invention, as I understand you, referring to the invention of the patent in suit, was made in the spring of 1878, and more thoroughly tested and perfected in the fall of the same year. Now please to state when it was first explained to your solicitor and directions given to him to apply for a patent for it?

A. In the month of October, 1878, about the middle of the
1577 month. Mr. Sawyer and I explained the whole subject-mat-
ter to Mr. Broadnax, solicitor for the Electro-Dynamic Light Co., and I as president of the company then requested him to apply for patents for this invention. Mr. Sawyer wrote out a statement of it, I think at that time, which was handed to Mr. Broadnax. Renewed applications and requests were made to Mr. Broadnax by me and I think Mr. Sawyer, until we parted the last of March or first of April, 1879, or certainly up to some time in January, 1879, from which time Mr. Sawyer was averse to making any applications, and from about the 1st of April, 1879, absolutely refused to sign any new applications, and thereafter never did sign any new applications for the inventions of Sawyer & Man as joint inventors, except under

some special arrangement by which he thought he was to obtain some personal advantage.

R. D. Q. 3016. Then as I understand you, all the time that elapsed after the invention was explained to Mr. Broadnax and he was directed to apply for a patent for it until the time that the application was actually filed, was from the middle of October, 1878, until the 9th of January, 1880, about fifteen months?

A. Yes, that is correct.

R. D. Q. 3017. During this time was the invention in public use?

A. No, not to my knowledge, until the latter part of the fall or the first of December, 1879. I first heard of it the latter part of December, 1879, as being put to use by Mr. Edison, from a publication in the New York Herald in the latter days of December, 1879.

R. D. Q. 3018. What, if any, effort was made to keep all knowledge of the invention from the public from the time it was made down to the time that you saw its use published by Mr. Edison in December, 1879?

A. We (Sawyer and I) always cautioned our workmen not to say anything about what we were doing. We never explained to the public who saw lamps with this kind of carbon in them, how
1578 the incandescent burners were made or of what kind of carbon
they consisted, because the thing was not patented, but we did explain the matter to our friends and to some of the stockholders of the Electro-Dynamic Light Co., and to Mr. Broadnax, the solicitor of that company, and possibly to a few other people in confidence whom we were endeavoring to interest with us in our electric lighting scheme, and it was our custom to keep our workshop and laboratory locked and exclude persons not interested with us from the same, did not explain our inventions or speak of them to parties not interested with us, unless in exceptional cases where we desired to interest them and get them to come in with us, and there was a door between our workshop and the room in which our exhibitions were made at 94 Walker street, which was kept locked when exhibitions were being made or the lamps were being exhibited.

R. D. Q. 3019. Now as I understand you, it was in the latter part of December, 1879, that you first knew of any one else having made or obtained knowledge of the invention of the patent in suit, and your application for such patent was made on January 9th, 1880. Is that correct?

A. Yes, except such persons as were interested with and friendly to us who obtained the knowledge from us, and I mean that the first knowledge I had of any one else but us making use of such invention was in the latter part of December, 1879, though it may have been that I heard of Mr. Edison's making use of paper a short time prior to the publication in the Herald of December 21, to which you refer but only a few days or a short time previous.

R. D. Q. 3020. Referring now to cross-question and answer 546 upon what did you predicate your expectation that a complete system of incandescent lighting would be worked out by Mr. Sawyer by the last of March, 1878?

A. Upon his statement to me to that effect.

R. D. Q. 3021. Referring now to cross-question and answer 750, please to state how thick the sheets of paper and the paper 1579 stock was from which you made the incandescent conductor by the method described in your answer to that question?

A. The papier-maché that we turned out in the lathe was from a sixteenth to an eighth of an inch thick. The paper sheets worked out on glass plates or laps before working were about a thirty-second of an inch thick. The papier-maché worked out on the glass plates or laps was somewhat thicker, perhaps a twentieth of an inch thick before working.

R. D. Q. 3022. You say also in answer to question 750 " We also cemented masses of carbon not of the shape or size of the conductor required." What was the shape and size of such masses of carbon of which you made the incandescent conductor by the method referred to in that answer?

A. Flat piece of carbon made of charcoal, papier-maché carbon, paper carbon and flat sheets of mineral carbon of a size and thickness to turn out a conductor from in the lathe.

R. D. Q. 3023. What was the length and tenuity of the incandescent conductors made by you by the methods described in your answer 750?

A. The smallest cross-section would be, I think, equivalent to the twentieth of an inch or less in diameter, the greatest length, that of the circumference of a circle, of an inch in diameter. Some of them were very much larger and shorter than these dimensions; some less than half an inch in length and some as large as a twelfth of an inch in diameter. Some of the longest were of the smallest cross-section.

R. D. Q. 3024. You have stated that by these methods you made incandescent illuminating conductors from mineral carbon as well as from carbon of fibrous origin. Of which of these carbons did you make conductors of the greatest length and tenuity?

1580 A. The fibrous carbon. The mineral carbons were all comparatively short and thick.

Adjourned till Thursday morning at 11 o'clock.

THURSDAY, *May* 31, 1888.

Met.

Present: Counsel as before, and the redirect examination of Mr. MAX was continued as follows:

R. D. Q. 3025. Referring again to your answer to cross-question 750, at what period of your work with Mr. Sawyer in making your incandescent electric lamps did you use the method described in that answer of making the incandescing conductor?

A. In the early part of our work while at 43 Centre street, in the spring of 1878.

R. D. Q. 3026. How long did you continue to practice that method of making such conductors?

A. With the mineral carbons, straight pencils, we sometimes cemented them to a lap of glass and rubbed them down to make them thinner and more tenuous and sometimes I think we used the same method with straight pencils cut out of deposit carbon pure and simple after the process described in our patent, of manufacturing deposit-carbon conductors, to smooth them off and make them a regular size throughout their length, till about the 1st of January, 1879, but as soon as we established in our minds the advantages of cutting the fibrous material to shape and size before carbonization for conductors we no longer practised the working down of fibrous conductors, I do not think we did anything of this kind with the fibrous conductors after the 1st of April, 1878, (it may, however, have been a little later than that) unless in some exceptional case, and none occurs to me now. It was better and more convenient 1581 to make the fibrous material to shape and size and then carbonize it.

R. D. Q. 3027. Do you mean to be understood that you continued to use that method more or less in cases where you used mineral or deposit carbon, down to about the 1st of January, 1879, but that in the case of the incandescing conductors, made from fibrous or textile material you did not use it after about the 1st of April, 1878, as you now recollect?

A. Yes, that is substantially what I mean, that is, that we sometimes and exceptionally used it with a hard carbon up to the 1st of January, 1879, but that I recollect no such use of it with fibrous carbons after about the 1st of April, 1878, but we cut or formed the fibrous carbon to size and shape before carbonization and did not work them down after they were carbonized.

R. D. Q. 3028. Why did you discontinue that method of making your incandescing conductors from carbon or fibrous origin?

A. For the reason that they were easier made and better carbons if made by cutting or forming to shape and size before carbonization. In short, it was possible to make these conductors in that way, but it was not practical, for in addition to the mechanical difficulty of making the conductor in that way, the carbon was not pure and homogeneous.

R. D. Q. 3029. Referring now to cross-question 853 in which it is inferred that you had compared incandescing conductors made from fibrous or textile material with incandescing conductors made from deposited carbon pure and simple, for the purpose of ascertaining which of two conductors of the same size and shape were the best; did you ever make such comparison?

—. ——.

R. D. Q. 3030. Of what size and length were such conductors used in making such comparison?

A. They were of comparatively short lengths, the longest 1582 possibly an inch or an inch and a half in length, the *the* shortest about half an inch in length. Their size was various from extreme tenuity of less than a thirty-second of an inch up to possibly a twelfth of an inch in cross-section. I do not know that any of the carbons of the smallest cross-section, were of deposit carbon pure and simple.

R. D. Q. 3031. Have you ever made, or do you know of any method that has ever been practised of making an illuminating conductor composed of carbon obtained "by electric action, pure and simple," having the length and tenuity of the illuminating conductor in the defendant's lamp Exhibit No. 21, by which the quality of such conductor could be compared with a conductor of equal length and tenuity made of fibrous carbon?

A. I have never made a conductor of the tenuity and length of that contained in the exhibit referred to of carbon obtained by electric action, pure and simple, and I know of no method that has been practised of making a conductor of this length, and tenuity of carbon obtained from electric action pure and simple, by which such a comparison as you mention could be made between such a conductor and a conductor of the same tenuity and length made from fibrous carbon. I had not intended to testify that I had made a comparison between two such conductors of such length and tenuity. I will add, that for the purpose of determining the quality of the carbon, of which the conductor is composed, or for determining the character of the conductor, I do not think it would be necessary to have conductors for comparison of the length and tenuity of the conductor in the exhibit referred to, and I do not think that comparison between two such conductors of the same tenuity and shorter length is sufficient to ascertain the quality of carbon of which the conductors are composed, and the character of the conductors, and I intended to be understood in testifying as having made such a comparison.

1583 R. D. Q. 3032. Which of two conductors of the length and tenuity referred to, the one made of fibrous or textile material and the other of carbon obtained by electric action pure and simple, would you consider the best conductor for incandescent electric lighting? I am referring to the length and tenuity of the conductor in the defendant's lamp Exhibit No. 21.

A. The one, the fibrous conductor, is an article readily made and practical. The other, the deposit-carbon conductor, I have testified that I have never made, and know of no practice by which it is made of such length and tenuity.

R. D. Q. 3033. Referring now to your method of making or treating carbons, described in the patent to Sawyer and Man, 211,262, assuming the illuminating or incandescent conductor made of carbon of fibrous origin, treated to the minimum extent described by you, both upon your cross-examination and your examination-in-chief, could you, after such treatment, separate the fibrous carbon from the deposited carbon?

A. No.

R. D. Q. 3034. Is it or not true, then, that the body of the illuminating conductor, after such minimum treatment, remains a conductor substantially of carbonized fibrous or textile material?

A. It is true that it so remains almost wholly of carbonized fibrous material, and of the same texture as before treatment, so that if the carbonized fibrous material were removed, there would be nothing left of the deposit carbon, even if it were in one mass or line, which would constitute or be a conductor, that mass or line would require

a microscope to find it, but as the deposited carbon in the treatment would be distributed upon the fibres of the fibrous material, the deposited carbon for each individual fibre of the conductor would be separate and by itself, constituting lines of hollow tubes of the size
of the ultimate fibres of the fibrous conductor, and the shells
1584 of these tubes would be so extremely thin and fragile as to
crumble to dust with the slightest touch.

R. D. Q. 3035. State whether or not, as the result of your experience, the fibrous carbon illuminating conductor by the treatment of it according to the process described in the Sawyer-Man patent is improved when such treatment is carried to the minimum extent mentioned by you in your testimony.

A. My experience is that it is improved.

R. D. Q. 3036. Referring to cross-question 1670 please to state in what places the incandescent lamp, as made by you and Mr. Sawyer, would be capable of competing with gas as stated in your answer to that question?

A. I do not think I could enumerate all the places where it would so compete with and drive out gas. I will mention such as occur to me; for the head-lights of locomotives, for use on steamships, especially in signalling at night; for use in places in which explosive gases existed; for use in mills where safety from fire is desirable, especially in flouring mills, sugar works and the parts of cotton mills where lint and dust are liable to cause fire or explosion; for use with the camera, and in all places where an intense light derived from substantially one focus is desirable; for use in lighting under water; for use in lighting for ornamentation, such as ornamental grounds and groves; for use as an illustrative apparatus in colleges and schools; for use where water power was available and cheap and near at hand for ordinary illumination.

R. D. Q. 3037. State, if you know of any way, that has ever been practiced of making a carbon incandescent conductor of the length and tenuity used in the incandescing electric lamps of to-day of fibrous or textile material other than by cutting, selecting or forming it to size before carbonization?

A. No, I do not.

Adjourned till Friday, June 1, 1888.

1585 FRIDAY, *June* 1, 1888.

Met.

Present: Counsel as before, and the redirect examination of Mr. MAN was continued as follows:

R. D. Q. 3038. Please to produce, if you can, a specimen of the cane obtained by you at Crookes' establishment in Fulton street in the fall of 1878, as mentioned in your answer to redirect question 3003.

A. I produce a specimen of such cane which I recently obtained from Mr. Crookes.

R. D. Q. 3039. This cane, as I understand, you gave to Mr. Myers or some other workman in your shop, with directions to carbonize and make incandescent conductors of it?

A. Yes, to Mr. Myers.

Specimen of cane offered in evidence and marked Complainant's Exhibit No. —, East India Cane, produced by Albon Man, June 1, 1888.

R. D. Q. 3040. Now, in making your longest and most tenuous incandescent-treated conductors of vegetable or fibrous carbon, how did you proceed in cases where such conductors were to be subjected to the minimum treatment according to the process of the patent of Sawyer & Man, 211,262?

A. We selected the fibrous material of the size and length desired, formed it to shape, and then carbonized it, and then treated it, or if the selected material was not already of a desired size, we formed it to the size desired, put it in the shape desired, then carbonized it and then treated it.

R. D. Q. 3041. Now, in making your incandescing conductors of pure deposited carbon obtained by electric action, how did you proceed?

1586 A. In the same manner as in the last answer, using selected fibrous material, selected or formed to size and shape, then treating it by the electrical process until the deposited carbon was of sufficient thickness of itself to form a conductor, then removing the vegetable fibrous carbon, leaving a conductor of pure-deposit carbon.

R. D. Q. 3042. In both cases, as I understand you, you began with an incandescing conductor made of carbonized fibrous or textile material?

A. Yes, a conductor of that kind selected or formed to shape and size before carbonization.

R. D. Q. 3043. Why did you use in the production of such conductors an incandescing conductor, made of carbonized, fibrous or textile material selected or formed of the proper size previous to carbonization?

A. In the first case, because we wanted to make a conductor for use in the lamps of carbonized fibrous material, only improved by the electrical treatment, and we knew of no other way in which long and tenuous conductors, such as some of those that we used, could be practically and easily produced except by the use of the fibrous carbons selected or formed to size and shape before carbonization. In the second case, that of the deposit carbon, pure and simple, we used the incandescing conductor of fibrous carbon selected or formed to shape and size before carbonization, in order to give the same shape to the deposit made upon it and we used the fibrous carbon, vegetable carbon, for this substratum on which the deposit was formed, because the vegetable carbon was soft and could be readily removed after the deposit was formed upon it, to leave the pure deposit carbon incandescent conductor. If we had used hard or mineral carbons for this purpose they were too hard to be removed and separated by tools from the deposit carbon, pure and simple, of which we wished to form a conductor, and the attempt to remove them would break the deposit carbon.

1587 R. D. Q. 3044. In the production of these conductors then, as I understand you, an incandescing conductor of carbonized fibrous or textile material was necessary to begin with?

A. Yes, we deemed it so.

R. D. Q. 3045. You have stated that the Wallaces, of Ansonia, were to manufacture your lamps under a royalty. Please to state what that royalty was to be and what it included?

A. My recollection of the thing is that they were to pay a royalty of three dollars per lamp for the use of all the inventions of Sawyer & Man, owned by the Electro-Dynamic Light Co., based upon the number of lamps in the different lighting systems or plants that they should establish. As an illustration, if a plant established by them was one containing a hundred lamps the royalty would be once for all, three hundred dollars, notwithstanding the lamps might be renewed in the same plant.

Adjourned to June 13, 1888.

1588 New York, *June* 12, 1888.

Met pursuant to agreement of counsel.

Present: Counsel as before, and the recross-examination of Mr. Man was commenced and continued as follows:

R. X Q. 3046. When testifying on your direct examin- in this suit did you recollect the getting of any bamboo for carbonization?

A. My recollection on the subject has been refreshed since I testified in regard to the matter. In my direct examination I recollected them getting somewhere and trying some endogenous wood of the larger or tree growth, such as some of the palms. I do not know which. If I knew, I have forgotten, and have forgotten where I got them. Since then I went to Crookes' place in Fulton street corner of Cliff street to get some lance-wood, such as I got from him and tried in 1878 and had my attention called to the getting of a great variety of woods from Crookes at that time which I took to 94 Walker street, carbonized, and had tried for the conductors of incandescent lamps, among which was another endogenous wood that I have not mentioned, that I am satisfied I then got and took to be tried at our workshop, No. 94 Walker street, with the other woods that I got from Crookes'. I have no further recollection in regard to the matter than that I got this wood, took it to our shop to be carbonized and tried, and have no recollection of the carbonizing and trying of this wood as distinguished from any of the others.

R. X Q. 3047. Who was it that called your attention to the getting of a great variety of woods from Crookes'?

A. I knew that I had got a variety of woods from Crookes' and my attention was called to the subject-matter by a young 1589 man that I have known as Harry Crooke, and the circumstances attending the getting of the wood were recalled by him and recollected by me.

R. X Q. 3048. What did he say to you?

A. He said that he took me up into the workshop where his father, or adopted father, as I have since learned he was, was at work, selected the woods while there, called my attention to several of them, among others this one endogenous wood (bamboo) which his father was then working, showed me the working of the wood which was then very peculiar and ingenious and gave me samples of it with the other woods.

R. X Q. 3049. This you had forgotten all about, as I understand?

A. Yes, I had not thought of it until that time.

R. X Q. 3050. Is it now your recollection that he suggested your taking this piece of bamboo and that you did not ask for it?

A. No, it is not. It is my recollection that I asked him for strong fibrous woods, all the kinds he had and that he took me up into the workshop to see what they had and showed me the different kinds of woods that his father was working, the bamboo and that he showed me the process of manufacture and that I asked him for the pieces of it.

R. X Q. 3051. You have, I understand, no recollection of having carbonized or tried it?

A. No, sir, not as distinguished from any of the others.

R. X Q. 3052. Did you ever get any more bamboo?

A. No, I don't think I ever did. I do not know that this was bamboo proper, it was cane, such as so-called split bamboo fish-poles are made of.

R. X Q. 3053. What do you mean by saying in your 3051st answer "not as distinguished from any of the others"?

A. The carbonizing at 94 Walker street, and preparing the
1590 conductors was mostly done by Mr. E. L. Myers, some of the
shaping by Mr. Sawyer. The woods I got were mostly prepared and carbonized by them and I believe that all the different kinds were tried that I took to the shop, but I am unable at this length of time to recollect and distinguish all the different kinds of woods, nor to testify, and I know that I have not named all that we got and all that were tried, but I am unable to testify positively in regard to several of the different kinds that I recollect, their individual use and trial. Among these is bamboo.

R. X Q. 3054. All that you know then is that getting a great variety of woods at Crooks', you got some bamboo, under the circumstances you have mentioned, and took it to the workshop to be used?

A. Yes, with the addition that I gave directions for the woods that I took there to be tried.

R. X Q. 3055. But whether bamboo was tried or not, you do not know?

A. I cannot answer; I cannot testify positively that it was.

R. X Q. 3056. In answer to your 3004th question you refer to woods having interlacing fibres. Do you remember what the kinds of woods having interlacing fibres that you tried were?

A. I don't know. It was one with interlacing fibres; I would know it if I saw it again, and have tried to find it, but have been unable to do so.

R. X Q. 3057. What endogenous woods have interlacing fibres?

A. The larger or tree growths such as some of the palms, I think.

R. X Q. 3058. Were conductors ever ma*k*e from this endogenous wood?

A. Yes, some straight pencils were made from it.

R. X Q. 3059. Was this wood tried to any extent?

1591 A. Not very extensively. A few batches of pencils were made from it.

R. X Q. 3060. How did it compare, in your estimation, with willow?

A. The conductors were very troublesome to make. They were good enough, but no preference was established for them in any way, and if I recollect rightly we thought the carbon was not as pure as the willow carbon.

R. X Q. 3061. In your 3007th answer, referring to the woods produced by you, you say they are similar woods to the endogenous woods with interlacing fibres which you tried. If I am correct in understanding you, you do not mean that you remember trying Grugru palm and mangrove; but what you do mean is that they are similar to these in being endogenous and having interlacing fibres?

A. As to the Grugru palm you are correct; but as to the mangrove, we did use lignum-vitæ, of which I understand the mangrove to be a species. As to this kind of mangrove it is not mainly an endogenous wood, but only, if I am right, takes on the endogenous form of growth in part only as to the interior of its aërial roots, which I think, from my investigation, are filled up so far as the pith or interior of these roots are concerned by endogenous growth, and also take an exogenous growth after they reach the ground and become new bodies for the trees. There are several kinds of woods which are commonly called in the neighborhood of their growth, mangrove. This one that I produce is called there mangrove and is lignum-vitæ, whether there are other kinds of lignum-vitæ I do not know. I only know that this kind of wood which I produce looks like that which we used which was called lignum-vitæ.

R. X Q. 3062. In your 2010th answer you say the company decided to go on with the manufacture and introduction of the lamps into use. How was this decision evidenced?

A. It was a decision reached at a board meeting of the company's trustees, and, I suppose, recorded in the minutes.

1592 R. X Q. 3063. Do you know where these minutes are?

A. No, I do not.

R. X Q. 3064. Was it explained to the board what lamp and apparatus the company had which they considered in practical shape for introduction?

A. I do not remember.

R. X Q. 3065. Do you remember what the lamp was and what the apparatus which it was decided to introduce and manufacture?

A. Only that it was like those which had been produced up to that time, and leaving a discretion as to modifications to the superintendent.

R. X Q. 3066. What apparatus other than lamps were to be manufactured and introduced?

A. Switches, resistances, regulators, meters, safety devices, cutouts and holders and connections for the lamps.

Adjourned till Wednesday, the 13th inst., at 10½ a. m.

NEW YORK, *June* 13, 1888.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and the witness; and after waiting an hour and a half, and no one appearing on behalf of defendant, the further examination of Mr. Man was adjourned till Thursday, the 14th inst., at 1 p. m.

THURSDAY, *June* 14, 1888.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and the witness. No one appearing for defendant the examination was adjourned till Friday, the 15th inst., at 1 p. m.

1593 FRIDAY, *June 15th*, 1888.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant. No one appearing for defendant, the examination was adjourned till Monday, the 18th, at 11 a. m.

NEW YORK, *June* 18, 1888.

Met.

Present: Counsel for the respective parties and the witness, and the examination of Mr. MAX was continued as follows:

R. X Q. 3067. You speak of the apparatus the company decided to manufacture. Please state what facilities for manufacture the company possessed.

A. I have already stated that fully. We had a workshop, tools and apparatus which I have named, and we had work made outside at a great variety of places.

R. X Q. 3068. Was it intended to do the manufacturing in the workshop or to have the articles made outside?

A. The main portion of the work was to be made outside; the setting up and assembling or putting together, and some other work, such as making carbon conductors, was to be done in the shop.

R. X Q. 3069. What horse power did you have available in the shop?

A. One small steam-engine. I don't remember the horse power, perhaps six horse power or less.

R. X Q. 3070. How many men did the machinery in the shop admit of employing with profit?

A. Half a dozen or more.

R. X Q. 3071. Can you tell me at what place outside of the shop the various articles or their parts were to be manufactured?

1594 A. I have already fully testified in regard to this matter. The glass-work at glass factories, the metal-work at different metal-working establishments of different kinds. I have already specified these as fully as I can.

R. X Q. 3072. What metal-working establishments was the metal-work to be done at?

A. I have already, as fully as I can, testified in regard to where we got the metal-work done. There was no direction given by the company that I recollect, that the metal-work, glass-work or other work was to be done at any particular place.

R. X Q. 3073. Where were the switches, resistances, regulators, meters, safety devices, cut-outs, and holders, referred to in your 3066th answer to be manufactured?

A. Partly in the shop and partly outside, as the other was.

R. X Q. 3074. Do you know at what places outside?

A. I do not remember that any direction was given by the company in regard to it. I cannot recollect the names of the people. They were brass-founders and machinists, and instrument-makers, and metal-spinners, and wire-coverers.

R. X Q. 3075. Did the company get any special tools or machinery after their decision to undertake the manufacture?

A. Yes, a great variety of patterns and samples, and we were all the time buying tools and having them made, of different kinds.

R. X Q. 3076. What special tools and machinery did the company get after its decision to manufacture, and to what extent did they go to fit up the shop so as to enable them to manufacture?

A. I cannot remember at this time to particularize all the things that were got or all the things that were done.

R. X Q. 3077. To what expense did the company go in this direction?

1595 A. I can't recollect the figures, but it was very large expense, thousands of dollars.

R. X Q. 3078. Do you mean it spent thousands of dollars in fitting up the workshop after its decision to manufacture?

A. Not the workshop of the company alone, but the apparatus used by all the different people who were manufacturing, all or most of them. The company had to pay for the special tools and apparatus of the different manufacturers necessary to produce the work cheaper and with facility, and for the time consumed in making such tools and apparatus. As an illustration: With H. L. Judd & Co., who made a large amount of metal-work for us, we paid for the making of tools, or rather machines for making the metal appliances of the base of the lamp, and for making the corrugated and folded conductors leading into the lamp, and for the metal apparatus underneath and above the diaphragm within the lamp. With others we did in the same manner, paid for the fitting up to make the different parts.

R. X Q. 3079. How much in all did the company pay for the special tools which Judd had to get for the purposes enumerated?

A. I cannot recollect. They made them.

R. X Q. 3080. About how much?

A. I can't tell.

R. X Q. 3081. What other manufacturers got in special tools for the doing of your work?

A. I cannot remember to name them. Special tools were made for producing the stop-cocks and grinding them, for pressing out the caps, for covers which covered the stop-cocks, for making the spun-metal caps which covered the base of the lamps, for making the clamping rings for the base of the lamps.

R. X Q. 3082. How much did the company expend in special tools and machinery for its workshop after its decision to manufacture?

1596 A. I do not know. No separate account was kept of the matter.

R. X Q. 3083. Can you tell me approximately?

A. Thousands of dollars were expended as a whole, but I do not know any way of distinguishing the expenditures for special tools and apparatus from the other expenditures.

R. X Q. 3084. Where did the company get the money they thus expended?

A. From the sale of its stock.

R. X Q. 3085. What was the capital of the company?

A. I can't recollect.

R. X Q. 3086. How much money was ever paid in.

A. That I can't recollect. I knew both, but it don't occur to me now, I should have to refresh my recollection to find out.

R. X Q. 3087. Did the company keep any books showing the monies paid in and expended?

A. Yes.

R. X Q. 3088. Where are they?

A. I don't know. The last I knew of them they were with Mr. Broadnax.

R. X Q. 3089. Were any meters actually constructed?

A. Yes.

R. X Q. 3100. By whom?

A. Two or three were partially constructed but not finished, in the workshop of the company in part, and in part by work outside. A complete meter was made I don't know who by, after Mr. Sawyer and I separated.

R. X Q. 3101. At what outside place was the work on the meters done?

A. I can't recollect where the parts were made.

R. X Q. 3102. Were any regulators made outside?

A. The parts were made outside.

R. X Q. 3103. Where?

A. I don't know.

1597 R. X Q. 3104. From whom were the special tools and machinery which the company got after its decision to manufacture obtained?

A. I can't recollect, a great number of people, here and there and everywhere.

R. X Q. 3105. You refer in your 3010th answer to an arrangement made with the Messrs. Wallace, of Ansonia, was that arrangement in writing?

A. Yes.

Counsel for defendant gives notice that they will move to strike from the record all the testimony of the witness given on his redirect examination relating to any arrangement made between the Electro-Dynamic Light Co., and the Messrs. Wallace, of Ansonia, and insist upon the original paper being produced.

Complainant's counsel, in response to the objection noted by defendant's counsel, calls his attention to the fact that it has already been proved that the agreement or contract referred to has been lost and cannot be produced.

R. X Q. 3106. I understand you do not know of your own knowledge what was done by the Messrs. Wallace under this agreement?

A. Only by reports from Mr. Wallace, Mr. Sawyer and — Mr. E. L. Myers, to the company, and to me as an officer.

R. X Q. 3107. You say in your 3010th answer that Mr. Sawyer was hired by the Electro-Dynamic Light Co., or its stockholders, which was it?

Objected to as immaterial and not cross-examination.

A. The stockholders contributed stock which they held, was sold, and the proceeds went to the company, and in part was paid to Mr. Sawyer.

R. X Q. 3108. Had the stock of the treasury of the company been exhausted?

Same objection.

1598 A. There was no stock in the treasury of the company, but stock was held by a trustee for the benefit of the company. I think that was not exhausted at the time.

R. X Q. 3109. Why did the stockholders individually contribute their stock?

Same objection.

A. In order to induce Mr. Sawyer to go to Ansonia and superintend the work there, or advise in regard to it and to interest Messrs. Wallace, who bought part of the stock that was sold.

R. X Q. 3110. Why was not the trust stock used for this purpose?

Same objection.

A. I do not know now, but I suppose it was for the purpose of keeping the company good, and not depleting it by the arrangement made with Mr. Sawyer and Mr. Wallace.

R. X Q. 3111. In your 3010th answer you say the Eastern Electric Manufacturing Co., to whom the patents were assigned, "agreed to go on with the manufacture and introduction of the lamps into use," with whom was this agreement made?

Same objection.

A. The agreement was between the Electro-Dynamic Light Co. and the Eastern Electric Manufacturing Co.

R. X Q. 3112. Was the agreement in writing?

Same objection.

A. I don't think so, but I don't recollect positively.

R. X Q. 3113. What was the agreement?

Same objection.

A. Before the patents were assigned to the Eastern Electric Manufacturing Co., or to Mr. W. H. Church, and from Church to that company, an agreement, after a great deal of negotiation, was reached between the two companies. Under that agreement the
assignment of the patent was made to the Eastern Electric
1599 Manufacturing Company, and that company agreed to go on
and manufacture and introduce the lamps and other apparatus. Whether this agreement was reduced to writing, I cannot now recollect.

R. X Q. 3114. In the same answer you say "They (the Eastern Electric Manufacturing Co.) did go on to manufacture some lamps," do you mean they manufactured them themselves, or had them made for them?

Same objection.

A. I think they did the manufacturing, in part, themselves in their workshop in Fulton street, New York, and in part had the work done outside, as the Electro-Dynamic Light Company did.

R. X Q. 3115. Did they acquire the tools and machinery of the Electro-Dynamic Light Co.?

Same objection.

A. No.

R. X Q. 3116. What became of them?

A. I bought them from the Electro-Dynamic Light Co., such as they had in their shops, and such as I could find with the different manufacturers who had done work for the company, except the engine, some of the pulleys and shafting, and some general tools, and one lathe, and perhaps some other things which were sold off to different people at the time when we closed the shop at 94 Walker street.

R. X Q. 3117. What have you done with them?

Same objection.

A. Part of them I still have, and part of them I have sold, and part of them I lent to Mr. Sawyer and never got them back again.

R. X Q. 3118. Did you keep, lend or sell the major part?

Same objection.

A. I think the major part is sold, much the major part in bulk, not in value, of what I had left after lending to Mr. Sawyer; I think I lent him about half what I got.

1600 R. X Q. 3119. What did you realize from those you sold?

Same objection.

A. I don't know; I sold them at odd times.

R. X Q. 3120. About how much?

Same objection.

A. Two or three to five hundred dollars I should think.

Adjourned for lunch.
Resumed after lunch.

R. X Q. 3121. What was the value of the special tools and machinery you bought from the Electro Dynamic Light Co., exclusive of dynamo machines and experimental apparatus; I refer to tools and machinery?

Same objection.

A. I do not know how much of it was only adapted to the special work which was to be performed, and not useful for other purposes. Some of it, such as lathes, tools, drills, was good in general workshops. Some of it I sold for old junk. Some of it I gave away to get rid of it, and the storing of it.

R. X Q. 3122. From what persons other than the Electro Dynamic Light Co. did you get the special tools and machinery which had been made for work to be done for that company?

Same objection.

A. Some of it I got from Mr. Judd, part of what we had, and part was burned up in their factory. Some of the patterns and forming tools I got from the metal-spinner in Centre street. Some of it Mr. George Sawyer went round and collected for me.

R. X Q. 3123. Is Judd the only person you can mention?

Same objection.

1601 A. He is the only person whose name I recollect.

R. X Q. 3124. Do you know, of your own knowledge, that the Eastern Electric Manufacturing Co. did any manufacturing?

Same objection.

A. Yes.

R. X Q. 3125. Did they fit up a workshop?

Same objection.

A. They had a workshop fitted up.

R. X Q. 3126. Capable of manufacturing on an extensive scale?

Same objection.

A. No; I think not on a very extensive scale, and not for the complete work of making and setting up lamps and other apparatus, but for assembling and setting up the manufactured parts of lamps and other apparatus.

R. X Q. 3127. Where was their workshop?

Same objection.

A. In Fulton street, New York, I can't remember where.

Witness here says:

"The tools and apparatus for making glass-work were most of them left at the glass factories where the glass-work was done. I never got them."

R. X Q. 3128. How much room did they have?

Same objection.

A. As I recollect it, one loft, or perhaps one loft and part of another, or the whole of another, I can't recollect.

R. X Q. 3129. What was the size of this loft?

Same objection.

A. I should think, speaking only from recollection, twenty-five by fifty or sixty feet deep, one loft complete and part or the whole of another loft of the same size.

R. X Q. 3130. To what extent did they go in the matter of tools and machinery?

1602 A. I don't know. They had a large amount of tools and machinery there.

R. X Q. 3131. You do not know as a matter of fact what work was done at this workshop?

Same objection.

A. Yes, I know some of the work that was done. I don't know the amount. There was a whole machine shop there of very special tools and large apparatus of all kinds.

R. X Q. 3132. Were these bought by the Eastern Electric Manufacturing Co. before or after its consolidation with the Electro Dynamic Light Company?

Same objection.

A. I don't know, part were bought before and part after.

R. X Q. 3133. You say they had work done outside. Do you know where?

Same objection.

A. No.

R. X Q. 3134. What has become of the tools and machinery of the company?

Same objection.

A. I don't know.

R. X Q. 3135. You were a large stockholder in that company?

Same objection.

A. I was a stockholder.

R. X Q. 3136. Do you know where the books of that company are showing the money expended by them in machinery, tools and experiments?

Same objection.

A. No.

R. X Q. 3137. Where did you last see them?

Same objection.

A. I do not know that I ever saw them, but it seems to me that they were shown to me at or about the time when the patents 1603 were assigned from the Eastern Co. to the Consolidated Co. with reference to the value of the tools, machinery and apparatus of the Eastern Co. or their cost. It may have been, however, that it was only the account *of* inventory that I saw and not the books.

R. X Q. 3138. Who was the last person, so far as you know, in whose custody they were?

Same objection.

A. I don't know that I ever knew in whose custody they were, and am not certain that I ever saw them.

R. X Q. 3139. In your 3010th answer, referring to this company you say "they did go on to * * * make commercial arrangements for their introduction into use." To what commercial arrangements were you referring?

Same objection.

A. A contract made with some Chicago people for the use of the lamps and apparatus in Chicago; a contract made with St. Louis people for the use and introduction of the lamps and other apparatus in St. Louis, a contract made with some Philadelphians of like character for the State of Pennsylvania, a contract made with Boston people, and other contracts, I can't remember where or with whom.

R. X Q. 3140. About when were they made?

Same objection.

A. After the sale of the patents by the Electro-Dynamic Co. to the Eastern, and before the sale from the Eastern to the Consolidated. I should say from some time in 1881 forward.

R. X Q. 3141. Were they in writing?

Same objection.

A. Yes.

R. X Q. 3142. Where are they?

Same objection.

A. I don't know.

Defendant's counsel objects to any testimony in regard to the subject-matter of these contracts and insists on the production of the originals.

1604 R. X Q. 3143. In the same answer you say the Consolidated Electric Light Co., after acquiring the patents, went on with the manufacture of the "lamps," &c. Do the consolidated company manufacture and sell a lamp similar to those manufactured in 1879 in Walker street?

Same objection.

A. Yes, in some respects.
R. X Q. 3144. In what respects?

Same objection.

A. They manufactured a lamp using a fibrous carbon; they treat the carbon after the Sawyer & Man patent. They support the conductors by a separate piece, similar to the base of the Sawyer-Man lamp, or equivalent to it; project this support into the interior of the lamp chamber, making it the equivalent of the diaphragm of the Sawyer & Man lamp. They make an arch or loop-shape carbon, similar to those that were made by Sawyer & Man. They use an exhausted or inert atmosphere, or both, as Sawyer & Man did, and they make the chamber wholly of glass, as Sawyer & Man did, and they produce light by incandescence of the conductor, as Sawyer & Man did. They make arrangements for connecting the lamp to conductors; they make arrangements in the lamp for connecting it with conductors and setting it upon fixtures, as Sawyer & Man did; and use a metal base around the bottom of the lamp, similar to the spun cap used by Sawyer & Man.
R. X Q. 3145. In what lamp does the consolidated company use an inert atmosphere?

Same objection.

A. In all their lamps.
R. X Q. 3148. At what pressure?

Same objection.

A. At an exhausted atmosphere; I don't know what pressure—very small and inert by reason of the exhaustion.
1605 R. X Q. 3149. What do you mean in your 3144th answer when you say the complainants use an exhausted or inert atmosphere?

Same objection.

A. Just what I said.
R. X Q. 3150. Do you use the terms as synonymous?

Same objection.

A. Yes.
R. X Q. 3151. In referring to the lamp made by complainant have you in mind one of their standard commercial lamps?

Same objection.

A. Their ordinary lamps, varying somewhat in form and in details of workmanship from time to time.

R. X Q. 3152. Do you consider the present standard lamp of complainant as substantially like Complainant's Exhibits Sawyer-Man Lamp No. 3, January 12, 1888; Sawyer-Man Lamp No. 2, January 12, 1888, and Sawyer-Man Lamp No. 4, January 12, 1888, with the exception of the form and substance of the carbon conductor?

Same objection.

A. They are not similar in form or in appearance, but they are similar in principle in the respects which I have stated, and involve the use of the same patents and inventions or devices in whole or in part.

R. X Q. 3153. Why does the complainant manufacture and sell its present form of lamp rather than such lamps as are shown in the exhibits?

Same objection.

A. I do not know, but suppose that they consider the present form of lamp superior.

R. X Q. 3154. In what respects?

Same objection.

A. In improved workmanship and skill, due to manufacture, and in simplification of the parts due to manufacture and the experience of use.

1606 R. X Q. 3155. Has the complainant any installation at the present time, so far as you know, where a thousand lamps are in circuit in multiple arc?

Same objection.

A. I do not know.

R. X Q. 3156. Do you know whether a thousand lamps such as they now manufacture could be put in a building like this (the Equitable) in multiple arc and run from dynamos in the basement?

Same objection.

A. I don't know, I think they could.

R. X Q. 3157. Have you any idea of the size of the copper wires required to be used to convey the current to the lamps in such an installation?

Same objection.

A. I have made no computation in regard to it.

R. X Q. 3158. What should you say was the resistance of the conductor of the lamp Exhibit Sawyer-Man Lamp, January 5th, 1888?

Same objection.

A. Less than an ohm.

R. X Q. 3159. Suppose you had a thousand such lamps in this building in multiple arc fed by a current from a dynamo in the basement what would have to be the diameter of the copper conductors?

Same objection.

A. Very large. Such a lamp is not well adapted to such an installation in multiple arc. Its resistance is too low.

R. X Q. 3160. When did the complainant first begin to manufacture and sell lamps?

Same objection.

A. Immediately after the organization of the company, I cannot now recollect the date. It is in the record in this case. I think it was in the fall of 1882.

R. X Q. 3161. Do you know whether there was then on the 1607 market a lamp having an appearance and structure of general similarity to the lamp the complainant now manufactures?

Same objection.

A. Yes, I think there were several kinds of lamps at that time on the market similar in general appearance. I don't know as to their details.

R. X Q. 3162. Was the Edison lamp one of those to which you refer?

Same objection.

A. I think the Edison lamp was similar in general appearance.

R. X Q. 3163. About when did the Eastern Electric Manufacturing Company cease to make or have made lamps for them?

Same objections.

A. I think about the same time the Consolidated was organized.

R. X Q. 3164. In your 3011th answer you say "each lamp was marked on a tag or label attached to it and a record entered of its performance." Referring to these records when testifying in the case on patent 211,262 between the same parties you said:

"X Q. 528. Who kept the records and what has become of them? A. Mr. Sawyer for the most part made out the cards, but the thing was very irregularly done and the records on the cards were very incomplete. I never knew what became of those that were thrown into Mr. Sawyer's desk, and the last time I recollect seeing any of them was in seeing them tied to a lamp that was given to Mr. Broadnax, counsel for the company, which had been handed by Mr. Sawyer to Mr. Arnoux to hold, showing the arched form of carbon at a time when Mr. Edison published something in the newspapers referring to the loop form of carbon; and also the card

1608 attached to another lamp which I gave to Mr. Broadnax to be used as an exhibit. What was done with the cards on those lamps then I do not know.

X Q. 529. What was the object of keeping these memoranda?

Same objection and notice.

A. As a guide to our experimental work.

X Q. 530. If that be so, what explanation have you to give of their incompleteness and your ignorance of them after they were thrown in Sawyer's desk?

Same objection and notice.

A. Their incompleteness was due to carelessness; their usefulness was in a great measure at an end for the purpose for which they were kept when the carbons or lamps were broken, or at an end, or changed."

Is such your present recollection of the facts?

Same objection.

A. Yes.

Adjourned till Tuesday, the 19th inst., at 1 p. m.

1609 TUESDAY, *June* 19, 1888.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Mr. MAN proceeded as follows:

Witness desires to state in addition to his last answer that since making the answers quoted in that question he has found one or two globes of lamps with cards or labels still adhering to them.

R. X Q. 3165. Have you such lamps in your possession?

Same objection.

A. There are two of the globes here present.

The globes referred to containing the labels are produced and marked in evidence "Complainant's Exhibit Globes with Labels, June 19, 1888."

R. X Q. 3166. In your 3015th answer you state you explained the whole matter of the invention in controversy to Mr. Broadnax and requested him to apply for a patent in October, 1878. Did Mr. Broadnax refuse to apply for a patent?

A. I don't know that he did.

R. X Q. 3167. Why did he not obey your request and apply for a patent?

A. I think there were several reasons.

R. X Q. 3168. Did he give you any reason why he did not?

A. Yes, he told me several times in regard to it.

R. X Q. 3169. You say in the same answer "Renewed applications and requests were made to Mr. Broadnax." Did he continue to disregard these applications and requests?

A. I don't think he ever disregarded them. On the contrary, he did a good deal of work in regard to them according to my best recollection.

1610 R. X Q. 3170. What reason did he give you for not obeying your request and applying for a patent?

A. One reason was that the thing would keep; that there was time enough to make the application; that he was very busy with other work for the company; that he was endeavoring to formulate claims in regard to the matter, and that he was in doubt in regard to the patentability of the invention because it was charcoal and charcoal had been used before in electric lighting.

R. X Q. 3171. Any other reasons?

A. I do not now remember any other statements in regard to it, for the delay.

R. X Q. 3172. From October, 1878, until March, 1879, what work did Mr Broadnax do for the company?

A. I don't think I could remember the details of the work he did, only some of it. He — a large number of applications for patents, foreign and domestic, for us, and was engaged in several interferences, to the best of my recollection.

R. X Q. 3173. How many applications do you think were filed between the times mentioned?

A. That I don't remember.

Witness desires to state that, discussion intervening, the last question was asked before he had completed his answer to the preceding question, which he does as follows:

Mr. Broadnax was also engaged in drawing contracts and agreements between the Electro-Dynamic Light Company and different people, attending the meetings of the board of the company, and made frequent journeys to Washington with reference to patents and interferences. This testimony I give as the best of my recollection of what he did and was doing for the Electro-Dynamic Light Company during the period you mention. My recollection is that his time was completely absorbed or nearly so, with the business of the company to the suspension of other business.

1611 R. X Q. 3174. What interferences was he conducting during this time?

A. I cannot remember them to name them.

R. X Q. 3175. How many times did he go to Washington?

A. I don't know. My recollection is a great many times.

R. X Q. 3176. About how many?

A. I can't recollect.

R. X Q. 3177. Can you give no idea?

A. No, not that would give any definite information on the subject.

R. X Q. 3178. What agreements or contracts did he prepare during this period?

A. That I can't recollect, only some of them.

R. X Q. 3179. What ones do you recollect?

A. I remember his drawing some agreements between the company and Mr. Sawyer and myself and two or three or more parties of gentlemen, called syndicates, and the Electro-Dynamic Light Co., having reference to foreign patents, and these are all that I do now recall.

R. X Q. 3180. Did Mr. Broadnax present bills for his services?

A. Yes, I think so.

R. X Q. 3181. Who to?

A. The Electro-Dynamic Light Co., I think.

R. X Q. 3182. Did those bills contain a statement of the services rendered?

A. I do not know.

R. X Q. 3183. Was the company informed in any way of the services performed by Mr. Broadnax?

A. Yes, they knew of everything that was done in a general way.

R. X Q. 3184. How were they informed?

A. At the board meetings.

R. X Q. 3185. By oral or written statement?

1612 A. Perhaps by both, I don't recollect. Mr. Broadnax was usually or frequently at the board meetings of the company and its officers, which were held very frequently, sometimes several times a week.

R. X Q. 3186. Were his bills paid by the company?

A. I think so.

R. X Q. 3187. By check?

A. I don't know whether by checks or cash.

R. X Q. 3188. Did the company have a bank account?

A. That I don't recollect, or whether he was paid by checks of the company or by checks of Closson & Hays, or others; I don't know if paid in checks and where payments were in cash, if any were made, whether the cash was handed to him by me or by Closson, Hays, or by other officers of the company. I don't know; I think, however, the payments were usually made by Closson & Hays, who acted as bankers for the company.

R. X Q. 3189. Did the Electro-Dynamic Light Co. ever have a bank account?

A. That I don't recollect, other than an account with Closson & Hays.

R. X Q. 3190. Did they have money in the hands of Closson & Hays and draw checks upon them?

A. They had money in the hands of Closson & Hays, whether they drew checks upon them I don't recollect.

R. X Q. 3191. Please explain in what way the debts of the Electro-Dynamic Light Co. were paid.

A. They were paid by the treasurer, who at the time was Mr. Jacob Hays, I think, or Mr. Lawrence Myers. Different members of the company at different times advanced money to the company, or sometimes paid some of its bills, for which the treasurer gave them credit.

R. X Q. 3192. Did the treasurer make payments out of his personal moneys?

1613 A. I do not remember that he did. He may have done so and charged it to the company till the money came in to him.

R. X — 3193. Did the treasurer keep a bank account as treasurer of the company?

A. I don't know, as I have said.

R. X Q. 3194. If the company had no bank account in what way did the company pay out or receive money as a company?

A. I have not said that it had not a bank account.

R. X Q. 3195. You have no recollection on the subject?

A. No.

R. X Q. 3196. Who kept the books and accounts of the company?

A. I think a clerk of Closson & Hays.

R. X Q. 3197. Where were the books kept?

A. At their office, corner Nassau and Pine streets.

R. X Q. 3198. Where was the stock book kept?

A. There.

R. X Q. 3199. Who wrote up the minutes?

A. The secretary.

R. X Q. 3200. Who was he?

A. I can't recollect; a part of the time Mr. Sawyer.

R. X Q. 3201. Where was the minute book kept?

A. At the same place.

R. X Q. 3202. Where was the office of the company?

A. At the same place.

R. X Q. 3203. Were the board meetings held there?

A. Yes, and at the workshops of the company.

R. X Q. 3204. Are Closson & Hays in business now?

A. I think not.

R. X Q. 3205. Who composed the firm?

A. I don't know; I know some of them.

R. X Q. 3206. Who?

A. Mr. Closson and Mr. Jabob Hays.

R. X Q. 3207. Are they living now?

A. I think they are.

1614 R. X Q. 3208. Were either of them a director or officer of the company?

A. Both of them, I think. I am not certain as to Mr. Closson.

R. X Q. 3209. Do you remember how much Mr. Broadnax's bill amounted to for the period mentioned?

A. I do not.

R. X Q. 3210. Do you know what has become of his bills or receipts?

A. I do not.

R. X Q. 3211. Nor of the books of the company?

A. No.

R. X Q. 3212. Were you or the company dissatisfied with Mr. Broadnax's failure to apply for a patent?

A. I only remember in regard to that, being urgent with Mr.

Broadnax that the thing should be done, and his rendering excuses in regard to it or giving reasons for the delay.

R. X Q. 3213. Do you remember whether you were satisfied with the reasons he gave?

A. I do not remember. I should think his reasons for delay, such as giving his attention to other matters more pressing, instead of to this particular case, were satisfactory to me at the time; but I did not agree with him as regards to the patentability of the invention, and frequently argued that question with him, and got him to go to the shops to see the thing and be better informed.

R. X Q. 3214. You speak of arguing the question of patentability with Mr. Broadnax. Please tell me what position he took on the subject in these discussions with you, and what positions you took.

A. I only recollect his telling me that he had endeavored to formulate specifications and claims upon the matter, which he said were not satisfactory to himself. I think he showed them to me, or some of them, and that he said
1615 that he was in doubt about getting any claims that
would stand. Mr. Sawyer and I had furnished him at first, about the middle of October, 1878, with a written statement of the invention. I think that after Mr. Broadnax had formulated some of the claims and specifications, that he and I discussed the matter as to the claims he had prepared, and that he was in doubt about any of them being good, and I thought they were, or some of them were, and that they would stand. I think I prepared, myself, some specifications and claims in regard to the matter after our first discussion of it, after he had prepared provisional or suggestive specifications and claims. I think that after that he prepared other specifications and claims which I saw, and I think these papers, including the original papers furnished to Mr. Broadnax by Sawyer and Man, were sent or given to Mr. Sawyer to revise, perhaps more than once, I think the last I saw of them they were with Mr. Sawyer. This occurred in the fall of 1878, and continued on until, perhaps, the 1st of January following, and perhaps later. Now I may not have given the direct order of things done or the discussion had. I cannot recall it to my memory to speak of it more clearly. I remember stating to Mr. Broadnax that the thing was new and evidently useful, and that it ought to be and I believe it was, patentable. I remember his referring to the matter of charcoal having been used before for electric lighting, and even if it was new it was not necessarily patentable, and any way there was no hurry about it, that we had two years in which to apply for the patent, and I remember him asking me if anybody else was using it, and if anybody knew of it except ourselves.

R. X Q. 3215. Were you aware of the previous use of charcoal or was Mr. Broadnax the first to inform you of it?

A. I was aware of it and I think the first papers I prepared for Mr. Broadnax and gave to him in October, 1878, contained a statement that charcoal had been used for incandescent lighting.

1616 R. X Q. 3216. Was there any discussion between you as to the arch form?

A. Yes, we both thought that was patentable at that time.

R. X Q. 3217. Do you both think it was new?

A. I believe we did, but subsequently discovered that an arch form of incandescent conductor, a something approaching that form, made of metal, had been previously used.

R. X Q. 3218. Did you discover this before or after the application was filed?

A. I think not till afterwards. I do not wish to be understood that the arch form for a carbon incandescent conductor was not then new, for I believe it was.

R. X Q. 3219. Can you not give me more clearly than you have the reasons given by Mr. Broadnax for thinking the invention was not patentable, and the reasons you gave him for thinking it was?

A. No, I could not.

R. X Q. 3220. Did the company know of these discussions between yourself and Mr. Broadnax?

A. I think the thing was talked of at the board meetings, as all our matters were freely talked of there, but the details of the talk between Mr. Broadnax and me I do not think they knew.

R. X Q. 3221. The invention belonged to the company, did it not?

A. It did.

R. X Q. 3222. Did you treat the subject as though you were dealing with your individual property, or did you consider it your duty to be guided by what the owners of the property might wish, and in order that they might act intelligently keep them fully informed?

A. I don't know what you mean. I was acting for the company in regard to an invention where I was co-inventor; I was president of the company and was acting solely for its interests, 1617 and my personal interests through the company. I had no secrets from my fellow-members of the board and did not endeavor to keep anything from them, if that is what you mean, and tried to keep them fully advised of all that was being done.

R. X Q. 3223. Did any members of the board know of the discussions between yourself and Mr. Broadnax on the subject-matter of this invention, and your requests to him to apply for a patent?

A. I don't know further than that the policy of the company was to get patents for all inventions as fast as could be done consistently, and that I was instructed to carry out that policy. As to how much of the details of the different patents the different members of the board or any of them knew, I cannot at this length of time state.

R. X Q. 3224. Did any members of the board know of Mr. Broadnax's delay in the matter?

A. I do not remember.

R. X Q. 3225. What were Mr. Broadnax's habits so far as you knew with reference to promptness and diligence in attending to the affairs of the company?

A. I do not think we ever made any complaint of Mr. Broadnax in regard to promptness and diligence.

R. X Q. 3226. The latter part of your 3015th answer might create the impression that after April, 1879, and before the application was in fact drawn up, Mr. Sawyer refused to sign an application for a patent on the invention in controversy, such is not the fact, however, as I understand?

A. I intended to be so understood. Mr. Sawyer refused to sign any and all applications for joint inventions of Sawyer and Man. I do not mean to be understood that an application for this particular invention was presented to Mr. Sawyer on behalf of the Electro-Dynamic Light Co. after he refused to sign all and every application for the joint inventions of Sawyer and Man, until the application was prepared which resulted in the patent in suit, which he did sign.

1618 R. X Q. 3227. Was an application for a patent in the invention in controversy ever presented to Mr. Sawyer with a request that he execute the same until the application which resulted in the patent in suit was presented to him?

A. Yes, I think so.

R. X Q. 3228. When?

A. In the fall of 1878, or early in January, 1879.

R. X Q. 3229. By whom?

A. I think the papers were prepared by Mr. Broadnax, and sent or given to Mr. Sawyer to modify and execute them.

R. X Q. 3230. And Sawyer refused?

A. Sawyer did not do it.

R. X Q. 3231. What reason did he give?

A. I have reference to the papers that I have before referred to in regard to this matter which were sent to Mr. Sawyer or given to him by Mr. Broadnax for correction and amendment. I do not remember talking with Mr. Sawyer about the matter until some time in February or March, 1879, after these papers were given to him. At that time I went over with Mr. Sawyer the unpatented inventions of Sawyer and Man, among others this subject-matter, with a view to get him to sign applications for patents for all of them. He refused to do so, but more subsequently consented to sign certain applications and assignments and refused to execute any others. The reasons he gave were, as he claimed, that the company was not treating him fairly, and that he was going to sever his connection from the company, and if he could not continue as superintendent that he would do all he could to injure the company, in substance, or at least that he would not do anything to help the company that he was not compelled to.

Adjourned till Wednesday, the 20th inst., at 10½ a. m.

1619 WEDNESDAY, *June 20th*, 1888.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Mr. MAN was continued as follows:

R. X Q. 3232. Do you feel quite positive that an application covering the invention of the patent in suit was prepared by Mr. Broadnax, and sent or brought to Mr. Sawyer for execution?

A. Yes, for examination, correction and execution.

R. X Q. 3233. Have you seen the application that was sent him?

A. I think the papers were shown to me by Mr. Broadnax before they went to Mr. Sawyer.

R. X Q. 3234. Were you satisfied with the application as prepared and sent?

A. I do not remember enough about it to state.

R. X Q. 3235. Was the execution in the form for execution and filing?

A. I am not certain.

R. X Q. 3236. Had you signed it?

A. No, sir, I don't think I had, or at least I do not remember that I had, but I may have done so.

R. X Q. 3237. How do you know such a paper or application was sent or given to Mr. Sawyer for correction and execution?

A. I only know of it as one of the things that I was trying to get done and to get Mr. Sawyer to do, and by another fact as follows: Some little time, a few days as my recollection goes, after the shop at 94 Walker street was closed, and while Mr. Sawyer had an office at the corner of the alley on Walker street, between Elm and Broadway, Mr. Broadnax at my request went there to see Mr. Sawyer and get him to execute some applications for patents, among others, one for this invention. He came
1620 from Mr. Sawyer's place directly to my office, No. 3 Mercer
street, and reported to me that Mr. Sawyer refused to execute any paper. The same day, or the next day, I went to see Mr. Sawyer and tried to induce him to execute the papers that Mr. Broadnax had prepared, and he would not. I feel confident that among these papers was an application for a patent for this invention, and that Mr. Broadnax either took it to him there then, or that Mr. Sawyer had it there then, and the best of my recollection is, that it was another and renewed application than the one or ones previously sent to Mr. Sawyer; but my recollection is not sufficient to swear positively to it. But in confirmation of the matter I remember talking with Mr. Sawyer about this invention when I went to see him after Mr. Broadnax called on him.

R. X Q. 3238. Did Mr. Broadnax tell you he had prepared and sent an application for a patent on this invention to Mr. Sawyer in the fall of 1878, or in January, 1879, for correction and execution?

A. I can't undertake to remember the conversation between Mr. Broadnax and myself at this length of time in detail. Whether Mr. Broadnax told me so, whether I derived the information from Mr. Sawyer or from myself handing him the papers, I cannot say.

R. X Q. 3239. Did you bring him the application to sign?

A. I don't know.

R. X Q. 3240. Did he ever tell you he had received such an application?

A. He talked with me about the application and its contents, and about Mr. Broadnax's opinion in regard to patentability.

R. X Q. 3241. Did you ever ask him whether he had received such an application?

A. I don't remember.

R. X Q. 3242. Did he ever show you any application?

A. As I have said, or intended to say, my best recollections
1621 of the matter are, that Mr. Sawyer and I looked over the papers together, but whether we did or not, I cannot be certain, or whether we simply talked about and discussed them as a matter known to both of us.

R. X Q. 3243. Have you any distinct recollection of seeing an application for a patent on this invention in Mr. Sawyer's possession?

A. As I have said before, I think and believe that I did, but as remembering a distinct paper in regard to the subject-matter which I saw in Mr. Sawyer's possession, I cannot say that I distinctly and positively remember it, but only that I distinctly and positively recollect the preparation of such papers for Mr. Sawyer's revision and execution, and recollect talking with him about them after the papers were prepared and he had them.

R. X Q. 3244. If it be the fact that an application for a patent on the invention in controversy was prepared and sent to Mr. Sawyer for execution, in the fall of 1878, or in January, 1879, as you think and believe, can you tell me whether the company was informed of such fact?

A. I, as president of the company and chairman of its executive committee, was informed of the fact, which is, I suppose, information to the company.

R. X Q. 3245. Who were the others on the executive committee?

A. I think Mr. Sawyer was one; I do not recollect who the other was, but my impression is that Mr. Lawrence Myers was the other; I should think so, but I can't recollect.

R. X Q. 3246. Who, on the board, if any one, was informed that such application had been prepared and sent to Mr. Sawyer?

A. I don't know other than I have stated.

R. X Q. 3247. Do you remember whether you discussed the specific application with Mr. Sawyer, and whether he refused to sign it?

1622 A. Yes, I remember discussing the application with Mr. Sawyer and Mr. Broadnax's ideas in regard to patentability, and I also remember discussing the subject-matter with him before the first memorandum was sent to Mr. Broadnax in October, 1878, and afterwards from that time forward until in January, 1879, at several times, and again I remember trying to get him to complete and execute the application for a patent for this invention shortly before we left 94 Walker street, when he positively refused to do so. And again, after Mr. Broadnax visited him at his office, at the corner of the lane or alleyway and Walker street, when he positively refused to execute any application. I remember subsequent conversations with him on the subject at different times, up to and shortly before the application was made, which resulted in the patent at which he refused to unite with me in any applications for patents for the benefit of the company.

R. X Q. 3248. In your interviews with Mr. Sawyer over this specific application sent to him for execution between October, 1878, and January, 1879, is it your recollection that he refused to sign the application, or objected to its claims and statements?

A. It is my recollection that he simply neglected the matter, and that I urged him to go on and complete it; not that he objected to anything that Mr. Broadnax had done, or any claim that Mr. Broadnax had prepared.

R X Q. 3249. What was it Mr. Sawyer neglected; to sign the application or to criticise and correct it?

A. To revise and sign it.

R. X Q. 3250. Did he ever express himself to you as satisfied or dissatisfied with its statement and claims?

A. Well, I don't recollect in those exact terms; I remember his stating, in substance, that he could better or improve the statement or claims, or both, and I remember his discussing with me whether an application simply covering the loop or arch form of the
1623 conductor, cut or made to shape and size before carbonization,
would not be sufficient without any reference to the character of the carbons, as to which Mr. Broadnax had expressed his doubts as to patentability.

R. X Q. 3251. Was any other application covering the invention of the patent in suit prepared than the one which you think was sent to Mr. Sawyer for correction and execution between October, 1878, and January, 1879, until the application which was filed was prepared?

A. I have said that I think Mr. Broadnax prepared a new application which he presented to Mr. Sawyer for execution, when he called upon him at his office, at the corner of Walker street and the alley. Of this I am not positive, but it is the best of my recollection.

R. X Q. 3252. When was this?

A. Just after the shops at the corner of Walker and Elm streets were closed, I should say in the month of April, 1879.

R. X Q. 3253. Why was this second application prepared?

A. In order to get Mr. Sawyer to execute it.

R. X Q. 3254. Was not the first application satisfactory to him or you?

A. I don't know; it was not executed and Mr. Broadnax had several conferences with Mr. Sawyer about the matter before the time of preparing and presenting this last application in the fall of 1878, and early in 1879.

R. X Q. 3255. Can you give me no reason why this second application was prepared?

A. I can't recollect the details in regard to it. I assume that it was in order to get Mr. Sawyer to immediately execute and not delay, and perhaps to conform to what Mr. Sawyer's ideas and mine in regard to what the application should be, or what it should contain.

All after first sentence objected to as irresponsive.

1624 A. I know it was done to conform to my desire and request to bring the matter to a close.

R. X Q. 3256. How did the second application differ from the first?

A. I don't know that it differed at all, and I don't know but it did.

R. X Q. 3257. How do you know Sawyer ever received the second application?

A. From Mr. Broadnax telling me that he presented it to him, and Mr. Sawyer's admission to me that he had done so when I went to see him about it.

R. X Q. 3258. Did you ever execute this second application?

A. I do not remember whether I did or not.

R. X Q. 3259. Did you ever ask Sawyer to execute it?

A. Yes.

R. X Q. 3260. Was any one present?

A. Part of the time during the conference between him and me some one else was present. I think either Mr. Church or Mr. George Sawyer, and part of the time Mr. Sawyer and I were alone at my request.

R. X Q. 3261. Did Mr. Sawyer refuse to sign this second application, or object to its claims and statements?

A. He refused to sign any and all applications including the one for this invention.

R. X Q. 3262. Did he object to the statement or claims of this second application?

A. No; he simply objected to it because it was for the benefit of the Electro Dynamic Light Co.

R. X Q. 3263. What were the other applications which he objected to sign at this time?

A. I can't recollect what they were; there were several of them.

R. X Q. 3264. Mention those you do recollect.

1625 A. I don't recollect any of them to specify them without going through and looking up; I could not tell what they were.

R. X Q. 3265. What would you have to go through and look up?

A. The things that Sawyer and I had done together, which were not patented, and I do not know that I could now sufficiently refresh my recollection to tell what any of them were. I know that included among the papers which Mr. Broadnax then took to him were several assignments and several applications.

R. X Q. 3266. Do you remember whether any of the applications were ever executed and filed?

A. I don't know whether any of them were ever executed, but I cannot be certain.

R. X Q. 3267. Were any of the assignments executed?

A. Yes, I think some of the assignments or others for the same invention were subsequently executed by Mr. Sawyer.

R. X Q. 3268. Did you inform the company of Mr. Sawyer's refusal?

A. Yes, they all knew it, that is, his refusal to execute any papers for the benefit of the company.

R. X Q. 3269. Did they know of his refusal to execute this and other applications for patents?

A. I think so.

R. X Q. 3270. How were they informed of it, and who were informed.

A. I informed the board at a board meeting.

R. X Q. 3271. Did you explain to the board the several inventions which he had refused to sign applications for?

A. I don't know; I related to the board what had taken place between Mr. Broadnax and Mr. Sawyer, and between Mr. Sawyer and me in a general manner.

R. X Q. 3272. Who was present at the board meeting?

A. I cannot recollect.

R. X Q. 3273. Mention such as you do recollect.

1626 R. X Q. 3274. Who were the directors of the company at this time?

A. I do not recollect, I can recollect some of them.

R. X Q. 3275. Name those you do recollect.

A. Jacob Hays, Lawrence Myers, Wm. H. Hays, I think Mr. Hugh McCulloch, I think Mr. H. L. Judd. I was a director or trustee.

R. X Q. 3276. Which of these gentlemen were present?

A. I cannot recollect.

R. X Q. 3277. What action did the board take when you informed them of Mr. Sawyer's refusal?

A. If my recollection serves me they sent for Mr. Sawyer.

R. X Q. 3278. Did he come?

A. Either then or at a subsequent meeting he did.

R. X Q. 3279. Did you inform the board of your estimate of the value of the property for which application had been prepared, and which Mr. Sawyer refused to execute?

A. I do not remember.

R. X Q. 3280. Did the board or the company take any action to induce or compel Mr. Sawyer to sign the applications?

A. I have said they sent for Mr. Sawyer, and that at that or a subsequent meeting he was present for the purpose of inducing him to perform his agreements with the company and execute necessary and proper papers.

R. X Q. 3281. Were you present at the meeting referred to?

A. I was.

R. X Q. 3282. Who else was there?

A. I do not remember, a quorum of the board.

R. X Q. 3283. Mention whom you remember other than Mr. Sawyer and yourself.

A. I cannot remember to particularize.

R. X Q. 3284. What took place at this meeting?

A. Generally Mr. Sawyer refused to go on with the 1627 company, and said he would make a proposition to the company.

R. X Q. 3285. Did he refuse to execute the application?

A. He refused to do anything with the company other than to say that he would make a proposition to them.

R. X. Q. 3286. Was there such a discussion, or did you make such explanation as that the board were aware that he refused to execute applications for patents on inventions which the counsel for the company had prepared, and which inventions were the property of the company?

A. I think the board so understood it.

Adjourned till Friday the 22d inst., at 11 a. m.

1628 FRIDAY, *June* 22, 1888.

Met.

Present: Counsel as before, and the examination of Mr. MAN continued as follows:

R. X Q. 3288. What efforts, if any, were subsequently made by yourself or the company to induce Mr. Sawyer to sign the second application?

A. I cannot remember details. I can only say generally that I urged Mr. Sawyer a great many times from this time forward till the application was made which resulted in the patent, to unite with me in an effort to obtain a patent for the invention, and that Mr. Broadnax, counsel for the company, was directed and requested to apply to him to have the thing done, and I believe did so.

R. X Q. 3289. Did the company as a company do anything?

A. I don't remember further than my own action. The company acted through me.

R. X Q. 3290. At about what time was this second application given to Mr. Sawyer to execute?

A. You speak of it as a second application. I think it was, but do not wish to swear to the identity of papers. I have stated that my best recollection was that it was shortly after our leaving 94 Walker street and in the month of April, 1879, but I cannot undertake, after so long a period, to be positively definite as to them. It may have been a little earlier or a little later. I think the expression "spring of 1879," would positively cover the time.

R. X Q. 3291. What is your best recollection of when the meeting was held at which Mr. Sawyer was present?

A. I can only fix it as soon after Mr. Sawyer's refusal to execute any papers in the spring of 1879.

R. X Q. 3292. Did Mr. Sawyer persist in his refusal from the time of the meeting till January, 1880, when the application for the patent was filed?

1629 A. At different times after this and prior to the making of the application which was filed Mr. Sawyer promised me that he would execute an application for this invention, but sent to or applied to personally by Mr. Broadnax, neglected or refused or postponed doing anything about it, and did not so far as I know except to talk to me. In his talks with me he sometimes refused, sometimes postponed the matter, and sometimes promised me he would attend to it.

R. X Q. 3293. And does this represent his attitude from the time of the meeting till January, 1880?

A. No, not wholly. From some time in September, 1879, up to the making of the application which was filed, he was actively hostile to the Electro-Dynamic Light Co.

R. X Q. 3294. Now from the time of the board meeting, at which Sawyer was present, until September, did you inform the board of your and Mr. Broadnax's efforts to get Mr. Sawyer to sign this application, and of your inability to do so?

A. I do not remember.

R. X Q. 3295. Did the board consult counsel as to whether they could compel Mr. Sawyer to sign the application, or whether they could file it without his signature?

A. I do not remember.

R. X Q. 3296. Did the board do anything to protect their rights so far as you know?

A. I do not remember what they did about it further than my own efforts in charge of the matter of the company.

R. X Q. 3297. Did you inform them of your efforts and their failure?

A. I presume so, I don't remember in regard to it.

R. X Q. 3298. You say from September on he was actively hostile to the company. Did he peremptorily and positively refuse after September to execute the application?

A. He peremptorily and positively refused to do anything
1630 with the company, or for its benefit, unless the company
would grant to him a license for the use of all the inventions, which the company refused to do.

R. X Q. 3298. Did this refusal include the refusal to execute this application?

A. The refusal included every invention.

R. X Q. 3300. Do you mean to answer "yes" to my question?

A. In that way, yes.

R. X Q. 3301. Do you remember whether he was asked to sign this application after September?

A. I do not remember as a specific thing, until some short time before the application was filed.

R. X Q. 3302. Were the company aware of his refusal to do anything?

A. I think they were.

R. X Q. 3303. Did the company take any steps to secure their rights in this matter after September?

A. Yes.

R. X Q. 3304. What did they do?

A. They counseled with Mr. Broadnax in regard to the matter, as to what their rights were in a general manner, and what was best to be done under the circumstances.

R. X Q. 3305. Did he advise the company?

A. I do not remember what his advice was.

R. X Q. 3306. Between October, 1878, and January, 1880, Sawyer did at different times execute applications and assignments to the company, did he not?

A. Yes.

R. X Q. 3307. It appears from the exhibits in the case printed in the interference record, that numerous assignments were executed by Mr. Sawyer transferring property to the Electro-Dynamic Light Co. from October, 1878, to August, 1879; what explanation have you to offer for his executing these papers, and not executing the application to which you have referred?

A. I think I have already explained that fully.

1631 R. X Q. 3308. Perhaps so, but please do so again.

A. I have explained the delays in getting Mr. Sawyer to sign an application for this patent up to the time of the breaking up of the shop at 94 Walker street, that from some time before breaking up the shop the company was dissatisfied with Mr. Sawyer and his management as superintendent which Mr. Sawyer knew, and that Mr. Sawyer was averse to making applications during that time, and delayed and put them off, and that after Mr. Sawyer's discharge, as superintendent, and the breaking up of the shop, he only signed applications and assignments by special agreement or arrangement with him in each particular case by which he thought he was obtaining some personal advantage, or under which he was unable to get money or dispose of stock of the company which he held

R. X Q. 3309. On December 9, 1878, Sawyer joined in an assignment to the company of several applications for patents on his sole inventions. What special consideration or inducement was given him for this?

A. I did not state that there was any. It was done under his general agreement.

R. X Q. 3310. On December 9, 1878, Sawyer joined in an assignment to the company of certain joint applications signed by Sawyer and Man. Was any special consideration given him for this?

A. I have not stated that there was any special inducement for any of the assignments or applications made by him until his discharge as superindendent.

R. X Q. 3311. On July 30th, 1879, Sawyer executed an assignment to the company upon application for an electric lamp filed April 3d, 1879. What special inducement was offered or given him for this?

A. I cannot remember the details of the arrangements by which he was induced, from time to time, to sign applications or assignments after his discharge as superintendent. I can only say generally that at the time the arrangement was made with 1632 the Messrs. Wallace, under which Sawyer received a large consideration in money and otherwise, he agreed in substance to execute such papers, assignments and applications as the counsel to the company advised were necessary and proper, part of which he performed, as in the execution of the papers to which you refer, but frequently after repeated attempts to get him to do so, and by pushing him to perform what he had agreed and sometimes he was only induced to do so by finding for him purchasers of the stock of the company which he held, or by making loans to him. I cannot remember the details of the inducements to him in any particular case.

R. X Q. 3312. You do not remember then what, if any, special inducement or consideration, was given to him for the execution of the paper referred to?

A. No.

R. X Q. 3313. On the 3d of February, 1879, Sawyer and Man executed the assignment of a number of patents to the company; was any special inducement given to him for the execution of this paper?

A. I have already stated that I do not know of any special inducement to him to sign papers other than his general agreement prior to his discharge as superintendent.

R. X Q. 3314. On May 21st, 1879, Sawyer executed a general release in favor of yourself and others. What special inducement or consideration was given him for this?

A. I answer as before that I cannot recollect the inducement in any particular case. I remember it was given in connection with the arrangements made with the Messrs. Wallace.

R. X Q. 3315. On July 30, 1879, Sawyer executed an assignment of an application for a sole invention of his in electric lamps. What special consideration or inducement was offered him for this?

1633 A. I answer as before, that I do not remember the special inducement in any particular case.

R. X Q. 3316. Was Sawyer ever offered any special inducement or consideration to sign the applications which was prepared by Mr. Broadnax covering the patent in suit?

A. I don't remember.

R. X Q. 3317. Who conducted the interviews or negotiations with Mr. Sawyer with reference to the executions of these applications and assignments?

A. I some; Mr. Broadnax some; I think Mr. Jacob Hays some; I have reference to the papers made after his discharge as superintendent.

R. X Q. 3318. What explanation have you to offer for the sending of Mr. Sawyer to Ansonia by the company after his neglect or refusal to sign an application for a patent on an invention belonging to the company?

A. I do not think it needs explanation, and I do not desire to make any. Do you desire one?

R. X Q. 3319. I would not have asked the question if I had not.

A. I don't desire to make any explanation.

R. X Q. 3320. When the application for the patent in suit was filed, was either Mr. Cheever or Mr. Baldwin informed that a prior application had been prepared?

A. I don't remember.

R. X Q. 3321. You never told them?

A. I don't remember whether I did or not.

R. X Q. 3322. If the subject of this invention had been one of so much discussion between yourself and Mr. Broadnax, would it not have been a very natural thing to have done?

A. I don't know.

R. X Q. 3323. From the record in the interference between Weston and Sawyer-Man it appears that the minute book of the Electro-Dynamic Light Co. was in your possession on December 13, 1882; was it then in your possession?

1634 A. No, I think not, further than it was handed to me to refer to extracts from the minutes copied on pages 69 and 70 of the interference (printed) record of Edward Weston against Sawyer and Man.

R. X Q. 3324. Where was that testimony given?

A. If I recollect rightly, at my office, No. 3 Mercer street.

R. X Q. 3325. What is your recollection as to the custody of the book; was it in your possession, or was it brought there?

A. It is my recollection that it was brought there by Mr. Broadnax.

R. X Q. 3326. Did he leave it there or take it away?

A. I have no recollection.

R. X Q. 3327. Did you ever see the minute book after the occasion referred to?

A. I don't recollect.

R. X Q. 3328. Did you ever try to find it?

A. Yes.

R. X Q. 3329. Did you find it?

A. No, I do not think I did, but perhaps I did. I recollect trying to find it and not being able to do so. I mean that I don't know, but that after I saw it at my office I saw it again, and I don't know that I did, but at a subsequent period I searched thoroughly for it and could not find it.

R. X Q. 3330. The extracts from the minutes of May 20 speaks of "a royalty of three dollars a lamp for such lamps as they should put up." Does this refresh your recollection as to whether the royalty was to be three dollars a lamp whether such lamps were original or renewal lamps, or whether the royalty was to be paid on original lamps, and that renewals were not to be subject to royalty?

A. No, because at the same meeting as appears by the extract from the minutes, a committee was appointed to draw up 1635 the details and prepare the license. In regard to this whole matter permit me to say that it is my impression that the royalty was applicable only to the lamps as first put up, and not to renewal lamps, but in the absence of the agreement or license I do not wish to be understood as swearing positively that such was the fact.

R. X Q. 3331. From the minutes of Nov. 25th it would seem that an agreement had been made with Mr. Wallace, and that the company was directed to execute it. Was a written agreement ever made?

A. I think so, but I don't know where it is. It was cancelled afterwards.

R. X Q. 3332. Do you remember how the business was to be done under this agreement?

A. The Messrs. Wallace were to manufacture and sell under all the patents of the company and the inventions belonging to the company, all the different apparatus, and were to pay for their exclusive license to do so a royalty of three dollars per lamp as compensation for the use of all the inventions; and my impression is, but I cannot swear positively to the fact, that the royalty was limited to the lamps as first set up or installed, and not to renewal lamps or plants which they had previously set up and supplied with lamps. They were to sell to the public and make reports to the Electro-Dynamic Light Co.

Adjourned till Monday the 25th inst., at 11 a. m.

1636 NEW YORK, *June 25th*, 1888.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Mr. MAN was continued as follows:

R. X Q. 3333. Referring to your 3018th answer wherein you say—

"We (Sawyer and I) always cautioned our workmen not to say anything about what we were doing"

which of your workmen knew of this invention at the time to which you refer and was so cautioned by you?

A. We cautioned Mr. Wm. Sawyer, Mr. George Sawyer and Mr. E. L. Myers, and the others from time to time.

R. X Q. 3334. Please mention the names of the others to whom you refer.

A. There was a Mr. Keating and Mr. Sharp and the people who did work for us outside. Mr. Judd's folks, Mr. Lothrop and Mr. Edsall who knew most about our work in Judd's shops. I do not remember the names of others and I do not mean to say that all those I have named knew of this invention, though they may have done so, except Mr. Keating.

R. X Q. 3335. Who of Judd's folks do you think knew of it?

A. Edsall and Lothrop, if they did know about it, and Mr. H. L. Judd himself, possibly.

R. X Q. 3336. Are Edsall and Lothrop with Judd now?

A. I think they are, I don't know.

R. X Q. 3337. What were they employed as?

A. Foreman and superintendent.

R. X Q. 3338. At his factory in Brooklyn?

A. Yes, in State street, Brooklyn.

1637 R. X Q. 3339. Do you remember their first names?

A. I think Mr. Edsall's name was William; I do not remember Mr. Lothrop's.

R. X Q. 3340. In the answer above referred to you say: "We did explain the matter to our friends and some of the stockholders of the Electro Dynamic Light Co." Mention the friends to whom you explained it.

A. I cannot, except as to some few.

R. X Q. 3341. Mention the few.

A. I explained many of our matters to Mr. Wm. Halley and to Mr. James M. Jackson who were in the office with me at No. 3 Mercer street. I frequently explained matters to different members of the board of trustees of the Electro Dynamic Light Co. I remember explaining it to Mr. E. D. Griswold, a neighbor of mine, and to Mr. Allen, who was in the same office with Mr. Griswold; I remember explaining it to a neighbor, Mr. Rowe, of Brooklyn. Edward Rowe.

R. X Q. 3342. Was this all before the application was filed?

A. Yes, I think so; all of it.

R. X Q. 3343. Do you mean to be understood by 3339 answer that the matter of the invention in controversy was explained to the gentlemen you there mentioned?

A. Yes, or some of them.

R. X Q. 3344. Which of them?

A. I think it probable that it was explained to all of them, but I cannot be certain at this length of time. I explained our inventions generally to them, and therefore think this matter was included. It would be proper to say that I omitted Mr. Broadnax, counsel for the company, to whom very full explanations were give both by myself and Mr. Sawyer.

1638 R. X Q. 3345. Were Mr. Alley and Mr. Jackson in your employ?

A. They were my assistants in the Lorillard office.

R. X Q. 3346. What was Mr. Griswold's business?

A. He is a manufacturer of cotton goods in Massachusetts. He lives in Brooklyn.

R. X Q. 3347. What is Mr. Rowe's business?

A. I don't know that he has any business now. He was engaged in the straw-hat business, an importer.

R. X Q. 3348. To what stockholders of the Electro Dynamic Light Company was the matter explained?

A. I don't know; I should think to nearly all of them that I met. They frequently talked to me about our inventions.

R. X Q. 3349. If you were desirous of keeping the matter secret why did you explain it to the gentlemen named, if in fact you did do so?

A. I cannot remember the reasons. It was done in confidence with them.

Adjourned till Thursday the 28th inst., at 11 a. m.

1639 Met pursuant to adjournment.

Present: Counsel for complainant, and witness and counsel for defendant not appearing, adjourned to Monday, July 2, 1888, at 1 o'clock p. m.

JULY 2, 1888.

Met pursuant to adjournment, and counsel for defendant not appearing, adjourned to July 3, 1888, at 1 o'clock p. m.

NEW YORK, *July* 3, 1888.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Mr. MAN continued as follows:

R. X Q. 3348. If, as you say, applications covering the inventions in controversy were prepared and the subject of their preparation and execution was a matter of the extent of discussion your testimony would indicate, what explanation have you to make of the fact that in the interference between Sawyer-Man and Edison no reference was made or testimony produced as to these several things?

Objected to as immaterial and for the further reason as not cross-examination, as there was no question of laches raised or inquired into or even alleged.

A. I do not know that the matter needs explanation. So far as counsel and others are concerned, I am not in position to make explanation for them. So far as I myself am concerned, if my testimony in the interference does not refer to this subject-matter, it was because my attention was not called to it, and I was not questioned in regard to it that I recollect.

R. X Q. 3349. Do you remember in whose possession you last saw the memoranda in relation to this application or the application themselves?

A. In Broadnax, the counsel's hands, or Mr. Sawyer, I do not recollect which.

1640 R. X Q. 3350. You speak of selling some of the machinery which at one time belonged to the Electric Dynamic Light Co. Do you remember to whom you sold it?

A. I sold a lathe, lathe tools and other tools to a Mr. Bigbee in Brooklyn. I sold a lot of stop-cocks and chemical apparatus, retorts, receivers and I don't know what, all to a dealer in such things. I don't know what his name was. He came to the place in Pacific street, where they were, and selected them out. I sold several parcels to different old-material men. I don't know their names. I sold some gearing and counter-shafts to a machinery man in Centre street. I don't recollect who else I sold to at different times, and I don't recollect the names of any of the parties except Mr. Bigbee.

R. X Q. 3351. You have mentioned the names of several gentlemen to whom you believed you explained, or who were informed in other ways of the making of the invention in controversy prior to the application. Why were they not called in the interference?

A. I don't know. I suppose because their testimony was not necessary or not thought to be so by counsel managing the case.

R. X Q. 3352. Did the Eastern Electric Manufacturing Company ever have a bank account?

A. I don't know.

R. X Q. 3353. Do you know where the books of the Eastern Electric Light Co. are, or any of them?

A. No.

Recross-examination closed.

1641 Questions by Mr. BROADNAX, complainant's counsel:

R. R. D. Q. 3354. In answer to recross 3318, and also in answer to question 3319, you stated that you did not desire to make any explanation of the sending of Mr. Sawyer to Ansonia by the Electro-Dynamic Light Co. after his neglect or refusal to sign an application for a patent on an invention belonging to the company. Please to state what your recollection is of the reason why Mr. Sawyer was sent to Ansonia after such a refusal or neglect to sign such application.

A. As I stated before, I do not desire to go into that matter, because I do not consider it necessary to the case; I have nothing to conceal in regard to it. Do you consider it necessary that I should make answer. If you do, I will do so.

R. R. D. Q. 3355. Of course I want an answer, or an explanation, if there be one?

A. I have already testified that the company had refused to go on with Mr. Sawyer as superintendent of its workshops, and that Mr. Sawyer insisted upon it that he should be such superintendent or the work should not go on. Things had come to such a pass that there was violent antagonism between the company and Mr. Sawyer; on his part, at least. There was nobody but myself and in part, Mr. E. L. Myers, a very young man and inexperienced in manufacturing, who knew about the work of the company; I could not give my attention to it, and the only remedy against Mr. Sawyer, on the part of the company, would be litigation, which was advised against by the counsel for the company. Under these circumstances a concession was made on the part of the company to Mr. Sawyer, and the Messrs. Wallace were brought in to do the manufacturing, in order that the manufacturing might go 1642 on, and Mr. Sawyer was paid to give advice and instruction at Mr. Wallace's place in Ansonia, but not as superintendent of the manufacture.

R. R. D. Q. 3356. Do you mean by your last answer that Mr. Sawyer was sent to Ansonia at that time for the purpose of conciliating him and to get him to remain sober and work diligently in harmony with the company's interests?

Objected to as leading and calling for a conclusion.

A. I mean that the arrangement was made to conciliate Mr. Sawyer and it was only entered into on his promise and agreement with the company to remain sober, and behave himself in other respects and work diligently and in all ways to promote the interests of the company.

R. R. D. Q. 3357. State whether or not Mr. Sawyer carried out the agreement referred to in your last answer?

A. He did not, as I have stated in testimony before.

1643 Questions by defendant's counsel, Mr. Tomlinson:

R. D. X Q. 3358. When this agreement was made was Sawyer conciliated and friendly?

A. For a little and until the matter was closed, and until he got the money and other considerations going to him under the agreement.

R. D. X Q. 3359. While in this mood was he asked to sign the application?

A. I don't know.

R. R. X Q. 3360. What was the necessity for conciliating Mr. Sawyer?

A. I have already stated that; to avoid litigation and prevent antagonism on his part, and to get him to work for the company's interests.

R. R. X Q. 3361. Why, when he was conciliated, was he not requested to sign this application?

A. I think he was. I do not know. I think he was by the counsel for the company, Mr. Broadnax, and I, myself, personally urged him to go on and complete the applications for patents for the unpatented inventions of himself and me together, including this, not specifically, but generally.

R. R. X Q. 3362. Did he refuse when Mr. Broadnax made the request?

A. I only know from the report sent to me and made to me by Mr. Broadnax that he did not do it, and Mr. Broadnax could not get him to do it.

R. R X Q. 3363. Was this the first indication that you had of Sawyer's unfriendliness after being conciliated by the agreement?

A. I don't remember. I do not mean to be understood in my answer before this that Mr. Sawyer did not sign any applications or papers after this, but that such was the complaint made to
1644 me by Mr. Broadnax, coupled with a request that I should see Mr. Sawyer about the matter, which I did.

R. R. X Q. 3364. If the fact be that Mr. Sawyer was placated by the agreement temporarily, and signed papers, while so placated, in the company's interest, what is your explanation of this application not having been signed with the others?

A. Mr. Sawyer only signed a few of the papers that were sent to him, and not all, but neglected or postponed them and did not execute them, and sometimes refused absolutely, as I was informed by Mr. Broadnax. The matter of this invention was one that he did not execute at that time.

R. R. X Q. 3365. But why can you give me no explanation as to this specific application?

A. Not more than others.

R. R. X Q. 3366. But you give me no explanation as to the others.

What was the reason for not signing the others, whatever you mean by "others"?

A. Much of the time Mr. Sawyer was not in condition to do any business. Further, I believe that Mr. Sawyer was actuated by a motive to retain a hold upon the company by not executing the papers which were sent to him and which he was requested to execute, in the hope that he could get further consideration for doing so, either by being retained in the payment of the company, or by getting further consideration for everything that he did for the company.

R. R. X Q. 3367. I do not understand from your answers the cause of the neglect or refusal of Sawyer to sign an application for this invention while he was conciliated by this agreement, nor do I understand whether you mean to say whether he was requested to do so. The exhibits in this case show that all the patents of Sawyer and Man were assigned by him to the company, that he assigned one or two patents and applications on his separate inventions and executed a general release to you and to the com-
1645 pany. When I ask you for an explanation of his not sign-
ing an application for this invention, you refer in general terms to his neglect or refusal to sign papers but do not give me any explanation why this specific paper was not signed?

A. Not as distinguished from the others.

ALBON MAN.

Sworn to before me this 12th day of July, A. D. 1888.

WM. T. FARNHAM,
Notary Public, County and State of New York.

Complainant's counsel here gives notice to defendant's counsel that he now closes his affirmative proofs in this case, but it is agreed between counsel, that if any merely formal matter has been inadvertently omitted which may be necessary or proper to complete the matter of the foregoing deposition, such as the filling in of dates, marking exhibits or offering as exhibits matters or papers which have been referred to, and the like, either party may put in such formal matters; and it is further agreed that no objection shall be taken to any of the proofs heretofore put in by complainant in this cause, upon the ground that it was not put in within the time limited by the rules of the court; nor shall any objection be taken to any such proofs upon the ground that it was not put in and certified to by one of the standing examiners of the court, but the whole of the foregoing deposition may be sworn to and certified before William T. Farnham, the notary public, by whom the deposition was actually taken, and such deposition and proof accompanying and making part of the same shall stand in the case the same to all intents and purposes, and have the same force and effect as if they had been taken before, sworn by and certified to by
1646 Timothy Griffiths, Esq., who was originally selected as the
examiner, before whom such proofs were to be taken.

Witnesses:—
John C. Tomlison, for defendant.
Broadnax & Bull, for complainant.
July 12th, 1888.

Q. 3368. I place in your hands a paper. Please to examine it and state what it is?

A. It is a paper belonging to the Electro-Dynamic Light Co., dated January 9th, 1880, signed by Charles A. Cheever, witnessed by W. K. Applebaugh and W. D. Baldwin, and is an agreement made by and between the Electro-Dynamic Light Co. and Charles A. Cheever, of the city of New York.

Q. 3369. Is this the same agreement referred to in your New York deposition relating to the provisional sale of the invention of the patent in suit, or a part thereof, to Charles A. Cheever?

A. It is.

Q. 3370. This is the original agreement, as I understand you, entered into by Mr. Cheever with the Electro-Dynamic Light Co.?

A. It is. I desire to state in this connection that from about 1881 or 1882, or prior thereto, I have not seen or had access to this paper until within the last few days, or at least have not seen it or been able to do so, although I inquired for it.

Paper offered in evidence and marked "Complainant's Exhibit Cheever agreement March 27, 1889."

1647 Q. 3371. What, if any, explanation do you wish to make of the paper which you have examined and identified as the agreement between the Electro-Dynamic Light Co. and Charles A. Cheever?

A. In the New York case in answer to cross-question 318, at page 407 of my printed testimony, the following question was asked me:

"What is your recollection as to whether under the arrangement with Mr. Cheever, the Electro-Dynamic Light Co. was to have the use of the invention?"

My answer was:

"My recollection of the matter is that the Electro-Dynamic Light Co. were to have the right to use the invention or some part of it by an understanding with Mr. Cheever."

To the next cross-question, No. 318*b*, (*318b*), same page, I was asked:

"Was this expressed in the written agreement?"

To this question I answered:

"My impression is it was not. My recollection is not clear about it, though."

The production of the written agreement with Mr. Cheever refreshes my recollection upon this subject, and I now remember that it was the intention to sell to Mr. Cheever only the arched horseshoe or V-shaped incandescent conductor, of whatever carbon it might be made, and not the conductor or other forms which does not comprise the whole invention but excludes, or was intended to exclude, conductors of other shapes of whatever carbon they might be formed or made.

Q 3372. I place in your hands Defendant's Exhibit Baldwin-Wallace Letter, January 8, 1880. Please to refer to the last clause of that letter and explain what it means, as you understand it?

A. The purpose of this letter was to make it perfectly plain that the Electro-Dynamic Light Co. controlled the application for a patent made in its behalf by an attorney, the writer of the 1648 letter, selected by Mr. Cheever, and to make it clear that Mr. Cheever's interest had reference only to the arched or pointed form, V-shaped carbon conductor.

Q. 3373. Do you mean without reference to the kind of carbon of which the conductor might be made?

A. I do.

Q. 3374. What was your understanding as to the novelty of the illuminating conductor being made in the form of an arch or loop or V-shape at the time this agreement with Cheever was made, irrespective of the kinds of carbon of which that conductor might be made?

A. At that time we deemed this form of incandescent conductor novel and original with us, and believed that we were the first to make incandescing conductors for electric lamps of those forms.

Q. 3375. Do you mean carbon incandescing conductors?

A. I do, and not only carbon but all incandescing conductors of that form, I think, but certainly those made of carbon.

Q. 3376. And was it that form of carbon conductor that you negotiated, or that the Electro-Dynamic Light Co. negotiated to sell to Mr. Cheever?

A. It was conductors of those forms, as they are mentioned in the contract, and those forms only.

Q. 3377. Please to examine the paper now handed you, and state what it is?

A. It is a copy of the Scientific American, a paper published in New York, dated December 7, 1878, containing a printed article and illustrations headed, "The Sawyer-Man electric lamp."

Q. 3378. How recently have you read the article mentioned by you, published in that paper, called the "Sawyer-Man electric lamp"?

A. I have not read it very recently. I will read it now.

Adjourned till 2 p. m.

1649 Resumed after adjournment.

Witness continues:

I have now read the article referred to.

Q. 3379. State, if you please, whether you find any reference in that article to the making of the illuminating conductor of carbonized, fibrous or textile material?

C. E. Light Co.
v.
McK. Light Co.
p. 1651

A. I see no reference in this article to the carbon conductor, as to how it was made or what it was made of.

Q. 3380. State, if you know, why there was no reference made in that article to the making of the illuminating conductor for your lamps, of carbonized, fibrous or textile material?

A. Because it had not been patented nor an application filed for it up to that time.

Q. 3381. Was it or not the purpose of yourself and Mr. Sawyer to keep all knowledge of that invention or discovery from the public before an application for a patent for it had been filed?

A. It was, not only in regard to this but also in regard to other things and other kinds of carbons, but we did disclose these things to a few people in confidence, and we could not keep it entirely from the knowledge of our workmen, or some of them.

Said Scientific American is offered in evidence (proof of publication being waived by defendant's counsel) and the same is marked "Complainant's Exhibit Scientific American Article, produced by Albon Man March 27, 1889. W. T. F., S. E."

Q. 3382. Have you recently measured the size of the rooms occupied by the Electro-Dynamic Light Co. as a shop on the corner of Walker and Elm streets?

A. I have.

Q. 3383. Please to give the several dimensions of those rooms, and please to make a diagram of them marking the dimensions on the diagram?

(Witness makes a diagram and hands it to Mr. Broadnax.)

1650 Q. 3384. Please to describe the diagram you have made, giving the dimensions marked on it?

(Here follows diagram marked p. 1651.)

A. The entrance was on Walker street, at the southwest corner of the building. The building stands on the northwest corner of Walker and Elm streets. A hall seven or eight feet wide, with a staircase, leads to the second story, extending back from Walker street, according to my measurement, seventeen feet six inches. From this hall in the second story a door led into the front room, on the corner of Walker and Elm streets. Another door opened from the hall into our engine-room. The front room, according to my measurement, was seventeen feet six inches deep on Elm street, and eighteen feet six inches wide on Walker street, with two windows on Walker street and one on Elm street. At the southwest corner of this room were two doors, together five feet wide, opening on a hatchway extending from the ground floor to the top of the building. At the northwest corner of this room a door opened into the back room, which, according to my measurement, was twenty-two feet six inches in length on Elm street, and about nineteen feet deep. Opening out of the back room and near to the door from the front room was an open space about three and a half

or four feet wide, leading into the engine-room, which is seven feet wide and about seventeen feet long. At the north end of the engine-room was a water-closet and sink. At the northwest corner of the building is a light-hole, a shaft about four feet square extending from the ground floor to the roof. There were two windows in the back room looking on Elm street, a brick partition wall between the back room and the engine-room, a brick partition wall between the engine-room and the hall, and a simple board, wooden partition between the hall and the front room and between the front and back room. The dimensions I have given are interior dimensions and are substantially accurate, but not positively so,
as I had to take them with a tape-line without assistance.
1652 The height of the rooms is about twelve feet to twelve feet
six inches. The height from the first floor to the roof in the light-hole at the northwest corner is about thirty-nine feet.

Q. 3385. These rooms of which you have made a diagram and given a description, as I understand you, occupied the whole of the second floor of the building?

A. The rooms and the hallway did, except the hoistway at the front end of the hallway on Walker street, about five feet by seven or eight.

Q. 3386. Do the description and the diagram you have made and given represent the rooms at the time they were occupied by the Electro-Dynamic Light Co.?

A. They do.

Q. 3387. What does the circular figure represent in the side room?

A. The engine and boiler.

Q. 3388. And this engine and boiler, as I understand the diagram, were accessible from the hall leading to the stairway and also through the door or passageway from the back room near the partition wall, between the two rooms?

A. Yes.

Diagram offered in evidence as part of the witness' deposition and the same is marked "Complainant's Exhibit Man's Diagram Walker and Elm Shop, March 27, 1887."

Q. 3389. Have you also measured the size of the shop occupied by you and Mr. Sawyer at 43 Centre street. If so, please to make a diagram marking the dimensions thereon?

A. I have made such a diagram and now produce it.

Q. 3390. Please to describe the diagram produced by you, giving its several dimensions?

A. The entrance to the premises was through a passageway from Centre street, and the premises were in a rear building or rear part
of a building up two flights of stairs, I think. The entrance
1653 to the room was at its northeast corner. There were windows
on the northwest and south sides of the room. The room is forty feet five inches long, east and west, and twenty-seven feet six inches wide, interior measurement. I should think it was ten or twelve feet high. This room was divided by a partition, partly of

canvas and partly of boards, into two rooms, the smaller one in the southeast corner, being about twelve feet wide, north and south, and twenty feet long, east and west. I have placed the window openings in the diagram from recollection only, and they are only substantially correct as to position and number. That is, there were several on each side of the room and several at the west end of the room.

Diagram offered in evidence and marked "Complainant's Exhibit Man's Diagram Centre-street Shop, March 27, 1889."

(Here follows diagram marked p. 1654.)

I had not seen this place until to-day since 1878. The diagram represents it as it was then.

Q. 3391. In addition to the electric lamps made by the Electro Dynamic Light Co., at the shop corner of Elm and Walker streets, what other and additional apparatus or parts of apparatus were made there as parts of your system of electric lighting?

A. Very little manufacturing, except of carbons and models and patterns, was done at No. 94 Walker street. The several parts of lamps, excepting carbon conductors, were divided up and the separate pieces were sent to different shops and mechanics to be manufactured and finished. The carbons were made at 94 Walker street, except the holders made of carbon, which were sent out with patters to be made. The several parts were returned by the mechanics who manufactured them, finished and ready to be assembled and set up, to our place, 94 Walker street. In addition to lamps we had manufactured in the same manner switches, resistances, parts of a regulator, parts of, or a complete meter, brackets, and
I don't know what all. Mr. Sawyer also started on his
1655–1665 own account the manufacture of a dynamo, by H. L.
Judd & Co., of Brooklyn, which was subsequently completed and paid for by the Electro-Dynamic Light Co., and the machine was sent to 94 Walker street while we were there, and tested and tried, and subsequently sent back to Mr. Judd in Brooklyn. I had intended in my correction of testimony in the New York case given this morning, to have mentioned this dynamo, as I was very thoroughly cross-examined in regard to dynamos in the New York case, and I failed to recall this one, and it is only within the last week or ten days and since I testified in the New York case, that it has come to my recollection.

While I am on the question of corrections I understand the testimony in the interference case with Edison is introduced in this case in some way, and in the printed testimony in the interference case and perhaps in the record I am made to *same*. "We went to 43 Centre street on the sixth or seventh of February, 1878. Of this there can be no doubt," or in substance this. The word February is a mistake, and should read March; whether it was a *lap-us lingua* of mine, or an error in taking down or printing the testimony, I do not know. The fact is, we went to 43 Centre street on the 6th or

7th of March, 1878. I well knew that fact and intended to so testify. I had at one time a letter from Mr. Sawyer, dated March 7th, 1878, showing the time of our going there and which is now handed to me by counsel for complainant, and I now produce it.

Q. 3392. Is this letter, referred to by you, in the handwriting of Mr. Sawyer, and was it received by you at about the time of its date?

A. It is, and it was received by me on the date of its date. In it I was asked to come to the place, 43 Centre street, that day, and did go there that day, though I think I also went there the day previous.

1666 Letter offered in evidence and marked "Complainant's Exhibit Sawyer's Letter, dated March 7th, 1878. March 27, 1889."

Q. 3393. Referring now to the dynamo mentioned by you in the previous answer as having been designed by Sawyer and made in whole or in part by Mr. Judd, is that the same dynamo that is described and claimed in letters patent of the United States granted to William E. Sawyer February 8th, 1881?

A. It is substantially the same thing.

Patent offered in evidence and marked "Complainant's Exhibit Sawyer's Dynamo Machine, patent of February 8, 1881. March 27, 1889."

Adjourned till Thursday, the 28th inst., at 11 a. m.

THURSDAY, *March* 28, 1889.

Met pursuant to adjournment.

Present: Amos Broadnax, Esq., for complainant and Grosvenor P. Lowrey and Walter K. Griffin, Esq., for defendant.

Q. 3394. I place in your hands letters patent of the United States granted to William E. Sawyer and Albon Man, No. 229,476, for improvement in electric switches, dated June 29, 1880. Please to state whether the switch illustrated and described in that patent was made or caused to be made by you and Mr. Sawyer for the Electro-Dynamic Light Co. while your shops were at the corner of Walker and Elm streets?

A. A large number of these switches, some of plaster of Paris add more of soapstone, were made for us while we were at 94 Walker street, and the parts sent to us at that place and assembled by ourselves or our workmen, and I have a large number of them now, and their parts.

1667 Patent offered in evidence and marked "Complainant's Exhibit Sawyer-Man Soapstone Switch Patent, March 28, 1889."

Q. 3395. I place in your hands letters patent of the United States, 210,152, dated November 19, 1878, granted to yourself and Wm. E. Sawyer for improvement in switches for electric lights. Please to state whether you and Mr. Sawyer made or caused to be made such switches at the shop of the Electro-Dynamic Light Co. at the corner of Walker and Elm streets, New York?

A. We had manufactured the parts for a large number of switches and safety devices shown in the illustration of this patent and set up a considerable number of them, I don't know how many, at our place, 94 Walker street, corner of Elm street, and I have some of the completed switches and many of the parts not set up now. We also made or caused to be made a large number of the switches embodying the idea of this patent, using circular instead of sliding movement, as embodied in a switch that I now produce, of which a considerable number were set up, I don't know how many, while we were at 94 Walker street, and of which I have a considerable number completed still, and the parts for many more. The switch produced has never been put to actual use, but was made in its different parts at different places by special tools and machinery adapted for its manufacture.

Patent offered in evidence and marked "Complainant's Exhibit Sawyer-Man Switch Patent 210,152, March 28th, 1889."

Switch produced by the witness also offered in evidence and marked "Complainant's Exhibit Sawyer-Man Switch, produced by Albon Man, March 28th, 1889."

Q. 3396. I place in your hands reissued letters patent, No. 10134, dated June 6, 1882, originally patented June 25, 1878, to yourself and Wm. E. Sawyer for electric lighting system. Please to state
whether the apparatus described and illustrated in that
1668 patent were made and used or caused to be made and used
by you and Mr. Sawyer at the shop of the Electro-Dynamic
Light Co., corner Walker and Elm streets, in this city?

A. They were.

Q. 3397. I place in your hands letters patent of the United States granted to yourself and Wm. E. Sawyer, No. 205,305, dated June 25, 1878, for improvement in regulators for electric lights. Please to state whether the apparatus described and illustrated in this patent was made or caused to be made by you and Mr. Sawyer and used at the shop of the Electro-Dynamic Light Co., corner of Walker and Elm streets, in this city?

A. Before going to the corner of Walker and Elm streets, according to the best of my recollection, patterns for the several parts of the apparatus described in this patent were made by us and the parts ordered. They, or some of them, were set up while we were at 94 Walker street. Whether any completed regulators were made, I do not recollect, and believe that at most only one was tried experimentally, but not in connection with our system of electric lights which we had set up for exhibition. My impression is that the parts for several regulators were assembled at the place, 94 Walker street, according to the plan of that patent, but not put to actual use. One regulator we ran experimentally complete, and I remember the parts shown in figure 3, as a whole, being set up and run there, and some of the parts separately from the rest.

Patent offered in evidence and marked "Complainant's Exhibit Sawyer-Man Regulator Patent, March 28, 1889."

Q. 3398. I place in your hands letters patent of the United States 210,151, dated Nov. 19, 1878, granted to Wm. E. Sawyer for electric meter. Please to state whether Mr. Sawyer or yourself, or the Electro-Dynamic Light Co. made or caused to be made the 1669 instrument or apparatus described and illustrated substantially in that patent at your shop, corner of Walker and Elm streets.

A. We did, and ran it there in connection with our electric lighting system, and made patterns and ordered the parts made for several more.

Said patent offered in evidence and marked *March 29, 1889," with the understanding on be-* "Complainant's Exhibit Sawyer-Man Electric Meter Patent, March 28, 1889."

Q. 3399. Between what dates were the several apparatus described and illustrated in these several patents to which we have been referring assembled, set up and used at the Walker and Elm street shop?

A. From the time we went to Walker and Elm streets, which, according to my recollection, I fix as the last of September, 1878, between that date and about the 15th, 16th or 17th of March, 1879, when I ceased to work in connection with Mr. Sawyer.

Q. 3400. And were all of the electric lamps referred to by you in your testimony in the New York case assembled and set up in that shop, 94 Walker street, during the same period?

A. Not all. The greater number were. Some were assembled and set up before we left 43 Centre street, in May or June, 1878. Some, and possibly a larger number, were assembled and set up after we left 43 Centre street, and before we went to 94 Walker street, at the shops at the corner of Howard and Centre streets.

Q. 3401. State as nearly as you can how many electric lamps were certainly set up and illuminated at the Walker and Elm street shop between the 1st of October, 1878, and the 15th of March, 1879.

A. I cannot fix that number, as I have stated before. It was a large number, in my judgment exceeding one hundred, and according to my recollection, as I look back upon it, running to 1670 between two and three hundred, but the manner of our work was such, lamps being used over and over again, and modified and changed in whole or in part, as to their interior works, that I cannot be certain in regard to the matter. I prefer to say that a very large number of lamps, without fixing definite numbers, was made, set up, and run there between the dates given in the question, and further, the manner of their manufacture in separate and distinct parts by workmen and manufacturers outside of our shop, at separate and distinct places, and the finished parts being brought to us there and set up by us and run. Whether lamps in use were new or modified, or refilled or refitted lamps is a matter which confuses my recollection.

Q. 3402. Please to state whether or not, between the dates you have given, Mr. William Sharp was employed at the shop of the Electro-Dynamic Light Co., corner of Walker and Elm.

A. He was, during part of the time.

Q. 3403. State as near as you can recollect when his employment at that shop commenced, and when it terminated.

A. He commenced work at that place, I should think, some time about the middle or last of October, and continued in the employment of the Electro-Dynamic Light Co., with possibly some intermissions of a few days at a time, until about the 15th, 16th or 17th of March, 1879, when I discharged him, and he was immediately re-employed by Mr. Wm. E. Sawyer, and continued at work at the same place, if I recollect correctly, with some intermissions, possibly, until about the middle of May, 1879, when the shops were broken up.

Q. 3405. Please to state the cause of Mr. Sharp's dismissal.

A. The Electro Dynamic Light Co. and I, as its president, were dissatisfied with Mr. Sawyer by reason of his drunkenness. I consulted with my cotrustees and with Mr. Sawyer, and remonstrated with him and told him that the work could not go 1671 on in that way, and, in substance, that if he continued his inebriation, we should shut up the shops. I consulted with my cotrustees, and it was agreed that if Mr. Sawyer did not mend his habits, I should shut up the shop and discharge the employees, except Mr. Edwin Myers. I went to the shop at the time when I discharged them, found Mr. Sawyer drunk, and his father and Mr. Sharp both under the influence of liquor. I immediately sent to the bank for money, discharged and paid off all but Mr. Myers, and stopped the work, so far as the Electro Dynamic Light Co. was concerned. I reported my action to the board at the meeting of the 20th of March, 1879, and it was approved. Before this meeting I had reported to the several trustees of the company what I had done, and why I had done it.

Q. 3406. Previous to the closing of the shop, as you have stated in your last answer, and the termination of your co-operation and work with Mr. Sawyer, had you admonished him that unless he discontinued his intemperate habits you would close the shop and discontinue your work with him?

A. I had.

Q. 3407. Frequently?

A. Very frequently.

Q. 3408. In closing the shop and discontinuing your work with Mr. Sawyer were you or the Electro-Dynamic Light Co. influenced in any way by the failure or any want of success of your electric lamp or inventions appertaining to your system of electric lighting?

A. In one sense we were, in another sense we were not. We believed in our system of electric lighting and in our electric lamps and in the patents that we had obtained and inventions that we had made, and believed that they were practical and successful, and it was not for any want of confidence in them that we stopped work,

but in the work done by Mr. Sawyer, in his drunkenness.
1672 As to its practicability we had not confidence, and in that sense our action was influenced in stopping the work, by want of practicability in the lamps made and set up by Mr. Sawyer, or under his direction while he was drunk, and we attributed this want of practicability solely to Mr. Sawyer's drunkenness.

Q. 3409. Had you any want of confidence in Mr. Sawyer to make the lamp and work all the inventions of your system if he would remain sober?

A. No, I had none, and I do not believe that any other members of the board of trustees had.

Q. 3410. Referring now again to Mr. Wm. Sharp, please to state what opportunity he had of observing what was being done at the Walker and Elm street shop during the time he was employed there?

A. Mr. Sharp's place of employment was in the back room. He had little or no opportunity to know what was going on in the front room, except as he occasionally went out and into the building in going to or returning from his work he might possibly pass through the front room. He had an opportunity to see, if he looked, the work that was going on in the back room except such as was conducted in the engine-room, which, from his position in the shop could not be seen by him ordinarily unless he left his work and went to the engine-room door or entrance. How much he knew or understood of it, I don't know. He was not an electrician or chemist. His business was a metal-finisher.

Q. 3411. What were his duties or work as a metal-finisher?

A. To make the pattern things according to drawings and directions for the different things he wanted to order made. And in this connection, the modifications which we wanted made in our lamps which we had run, were frequently if not usually placed in his hands. He sometimes assisted Mr. Myers or Wm. Sawyer in taking down lamps that had been run, but not usually, and in finishing up metal-work of all kinds.

1673 Q. 3412. In what capacity was he employed?

A. Simply as an ordinary workman, a mechanic.

Q. 3413. Did he occupy any confidential relation with either you or Mr. Sawyer?

A. We did not tell him of or discuss the things we wanted to do or accomplish in his presence or with him. His relations were only so far confidential that he was requested not to talk about the things that he did do, with any one outside.

Q. 3414. Did that request extend to anything that he saw?

A. Yes, and the request was general to all the workmen in the shop.

Q. 3415. Was it any part of his duty, or did he in fact assemble the several parts of the lamps and put them up at the shop?

A. That was not his ordinary work, but was done by Mr. Wm. Sawyer, Mr. Wm. E. Sawyer and Mr. Myers, ordinarily. I think, however, that Mr. Sharp may have put up a few lamps.

Q. 3416. Whose duty was it to make the carbons that were used in the lamps, and who, in fact, did make them and put them in the lamps?

A. Mr. Myers had charge of that matter under Mr. Wm. E. Sawyer and myself, and usually treated the carbons and put them in the lamps, exhausted and charged them and sealed them off. Mr. Wm. E. Sawyer, however, frequently put in carbons into the lamps, some that were made by himself, but mostly those that were made by Mr. Myers, and did a good deal of the electrical treatment of carbons which Mr. Myers ordinarily did, and Mr. Wm. Sawyer frequently put the carbons into the lamps and ordinarily set them up. Mr. Myers, under my direction, did all or nearly all the carbonizing in the furnace. I do not think Mr. Sharp had anything to do with carbon.

Q. 3417. In view of Mr. Sharp's position there, is it prob-
1674 able that he would know what the carbons were made of,
how they were carbonized, or what kind of carbons were put
in the lamps?

A. The fact is, that I thought that Mr. Sharp would know and recollect more than he appears to do by his testimony, at least as to the form of carbons and the carbonization and the materials carbonized. His opportunities for knowing were dependent only upon his own observation, and not upon information conveyed to him by us. As to the material of the carbons before treatment I should think it highly improbable that he could know what the material of the carbons actually treated was, further than that I think he saw the carbonization going on in the furnace by Mr. Myers and might have inferred that it was the carbons thus made that were being treated by Mr. Myers and Mr. Wm. E. Sawyer. After the carbons were treated I do not think Mr. Sharp could know what they were made of. The carbons when carbonized were taken care of and locked up by Mr. Wm. E. Sawyer in his desk in the front room and in the drawer of the table in the center of the front room to which Mr. Sharp had no access, of course. The carbons were given out by Mr. Sawyer to Mr. Myers to be treated and put in the lamps, and to his father to put in the lamps or in the holders for treatment.

Q. 3418. Was Mr. Wm. Sharp's employment and the condition and arrangement of the shop and the division of the work such that many different kinds of carbon could be made there and used in the lamps without Mr. Sharp's knowing anything about it, unless he was specially told of it?

A. Yes, such was the fact, and he could only know it by attending to that which was none of his business, or being told of it, but, at the same time, I had believed that Mr. Sharp, from the condition of things, must have positively known of the making of carbons
from paper, wood and other substances, as according to my
1675 recollection Mr. Sharp made several kinds of punches for
cutting out paper for carbons. It may be that I am mistaken in my recollection and that these punches were made by old Mr. Sawyer; still, even if Mr. Sharp made the punches, as they were not used in the back room, but all the material for carbons were cut

and shaped in the front room, he may not have known what they were for. I mean to say, in this, that there was abundant opportunity for Mr. Sharp not to know what was going on, and that he did, in fact, know, as I believed at the time, very lit-le of what was being done. That part only which he could see and observe while attending to his work with his back to the rest of the shop, ordinarily, but the carbonization was conducted in a room connecting to that in which he was, and it seems to me that if he had exercised any thought upon the matter he must have known that the carbonization was for the purpose of electric lighting, and some of the materials that were carbonized were in plain sight in his room, and it was no infrequent thing for the vegetable and fibrous carbons to be openly exposed on the table and on Mr. Sawyer's desk in the front room. It is true, however, that Mr. Sharp had no business whatever in the front room. Again, these carbons were taken by Mr. Myers and Mr. William E. Sawyer to the back room and treated upon the chemical platform right back of where Mr. Sharp usually worked. I think no explanation whatever was made to him, but he might have seen them.

Complainant's counsel states upon the record, in the presence of defendant's counsel, that, not having been able to get a copy of the deposition of Mr. William Sharp, he is unable to proceed with the examination of this witness as to Sharp's deposition, and, therefore, defers such further examination as to that deposition until he is able to get a copy of the same, and proceeds with the examination of the witness on another branch of the case.

Q. 3419. Please to state what, if any, correspondence you have
had with any one connected with the Edison Electric Light
1676 Co. as to uniting the interest of the Edison Electric Light
Co. with the interest of the Electro Dynamic Light Co. in
incandescent electric lighting, and please to give the name of the person or persons with whom you corresponded, either in writing or orally, as president of the Electro Dynamic Light Co.

A. I had a correspondence with Mr. Grosvenor P. Lowrey, counsel now present, to whom I was referred by Mr. Wright, of Drexel, Morgan & Co., as the attorney of the Edison Electric Light Interest or Company. I don't know whether it was a company or being promoted by Drexel, Morgan & Co., and in which I understood Mr. Lowrey to have some personal interest. In the fall of 1878, I invited Mr. Lowrey to our place, at No. 94 Walker street, and showed him our lights, or some of them, and some of the things we had. I had a conversation with him, I think, at my office, No. 3 Mercer street, upon the subject-matter of uniting in some way the Edison interest with the Sawyer and Man interest, with a view of preventing subsequent litigation and injurious competition. On the 30th of October, 1878, I received a letter from Mr. Lowrey, dated that day upon this subject-matter. On the 31st of October, 1878, I replied to that letter. On the 2d of November, 1878, I received another letter from Mr. Lowrey, dated that day, and on the 6th of November, 1878, I received another letter, dated that day, from him.

Q. 3420. How was this correspondence initiated between you and Mr. Lowrey?

A. First by my seeing glowing statements in the newspapers of what Mr. Edison was doing or about to do in incandescent electric lighting, and my thinking by the widespread notoriety of Mr. Edison in electric lighting and knowing what we ourselves had done, that it would be better to have Mr. Edison as a coworker than an opponent; and second, hearing that Drexel, Morgan & Co., with whom I had frequent business at the time, were interested with Mr. Edison, I took occasion to speak to Mr. Morgan 1677 of that firm, and tell him in substance that we, Sawyer & Man, had done a good deal in electric lighting by incandescence, had some very good inventions and patents in regard thereto, and some good lights, and expressed my views personally that good business policy would indicate the propriety of a union of interests between us in the field of incandescent lighting. Mr. Morgan referred me to Mr. Wright of that firm, as having charge of the subject-matter, and Mr. Wright referred me to Mr. Lowrey as the attorney and interested in the matter. I saw Mr. Lowrey in accordance with Mr. Wright's suggestion. Then, or soon afterwards, I invited him, in some way, to go to 94 Walker street and see what we had. The result was the correspondence between us, the dates of which I have given.

Q. 3421. Can you give the time of your first interview with Mr. Morgan?

A. No, except that it was a week or ten days, perhaps more, and it may not have been so long, before Mr. Lowrey visited 94 Walker street.

Q. 3422. After your first interview with Mr. Morgan, how much time elapsed before your interview with Mr. Wright?

A. I think it was the same day.

Q. 3423. How long after that before your interview with Mr. Lowrey?

A. At this length of time I cannot state with accuracy. My best recollection is, it was some days subsequent to my interview with Mr. Morgan and Mr. Wright, and it was several days after this before Mr. Lowrey came to 94 Walker street. I should think a week or more; perhaps it may have been two weeks.

Q. 3424. What was the nature of your business with Drexel, Morgan & Co. at that time?

A. Buying foreign exchange of them, and buying letters of credit for my clients.

1678 Q. 3425. Please to examine the paper now shown you and state if you recognize it as one of the letters referred to by you as having been received by you from Mr. Lowrey?

A. I do; that is the letter dated October 30th, to which I referred.

Letter offered in evidence and marked "Complainant's Exhibit, Lowrey Letter of Oct. 30, 1878. March 28, 1889."

Adjourned till Friday, the 29th inst., at 11 a. m.

NEW YORK, *March 29th*, 1889.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Mr. MAN was continued as follows:

Q. 3426. You have referred to a letter addressed to you by Mr. Lowrey, dated Nov. 2, 1878. Can you produce the original of that letter?

A. I cannot, and don't know where it is. The last I saw of it, it was in the hands of William E. Sawyer, then secretary of the Electro-Dynamic Light Co., to the best of my recollection.

Q. 3427. Have you made search for the letter?

A. I made search through my papers some time ago for all the papers connected with the Electro-Dynamic Light Co., and am confident I haven't got it.

Q. 3428. Do you know of your own knowledge that the record of that letter found in the minute book of the Electro-Dynamic Light Co. is a true copy of that letter?

A. I do. I compared all this correspondence, as recorded in the minute book with the original letter and press copy that I made of the letter. I wrote to Mr. Lowrey with the record in the minute book at the time they were made with Mr. William E. Sawyer, the then secretary of the company.

1679 The copy of said letter as recorded in the minute book of the Electro-Dynamo Light Co. is offered in evidence, and is marked "Complainant's Exhibit Lowrey's Letter of Nov. 2, 1878. March 29, 1889."

Counsel for defendant, Mr. Lowrey, being present, notwithstanding the general reservation of the right of objection till the close of Mr. Man's testimony, states that he will cause a search to be made for a letter-press copy of such letter, if it exists, and will produce it for the use of the complainant if found, but that as he has no recollection of such a letter, he now notes an objection to this method of proving the letter, that a sufficient ground had not been laid for producing a copy in place of the original, and that the original, if produced, and the copy are incompetent, irrelevant and immaterial as between the parties to this action and upon the issues thereof.

Q. 3429. Please to examine the paper now handed you and state if you recognize it as the original letter written you by Mr. Lowrey, November 6, 1878?

A. This is the original letter dated November 6, 1878, to which I referred, addressed to me by Mr. Lowrey, and received by me and recorded in the minute book of the Electro-Dynamic Light Co.

Letter offered in evidence and marked "Complainant's Exhibit Lowrey Letter of November 6, 1878. March 29, 1889."

Q. 3430. Are these three letters all the letters you received from Mr. Lowrey on the subject of this correspondence?

A. I can only say that I think so, and that I do not recollect any others.

Q. 3431. Are these letters in the handwriting of Mr. Lowrey and signed by him?

Mr. Lowrey being present and shown the letter of November 6,
says that the signature is his, and from examination of the
1680 two letters of October 30 and November 6, he has no doubt
they were both written in his office although the letter of
October 30th does not purport to be an original letter, but to be a
copy, both as to its body and signature, and he has no doubt that it
was written by his direction.

A. I think this answers your question fully. They are the original papers received by me from Mr. Lowrey.

Q. 3432. Was the other letter, I mean the letter of November 2, 1878, in the handwriting of Mr. Lowrey?

A. I think the letter of November 2nd purported to be a dictated letter from Mr. Lowrey. My impression is that it was in typewriting, but of this I am not certain. It may have been in manuscript. It is referred to in the letter signed by Mr. Lowrey, personally, dated November 6, 1878, and there stated to have been dictated to his stenographer by him.

Q. 3433. What, if any, answer did you make to these letters that was in writing?

A. I answered according to my recollection in writing, only the letter from Mr. Lowrey to me, dated October 30, 1878, and my answer thereto is recorded on pages 31, 32, 33 and 34 of the minute book of the Electro-Dynamic Light Co. My letter is dated October 31, 1878, and its receipt by Mr. Lowrey is acknowledged in his letter to me of November 6, 1878, and in his letter of November 2, 1878.

Q. 3434. Can you produce the original of the letter referred to by you in your last answer?

A. I cannot.

Q. 3435. Why?

A. I sent it to Mr. Lowrey.

Q. 3436. Was it recorded in the minute book before you sent it to Mr. Lowrey?

A. It was not.

Q. 3437. From what was the record made in the minute book of that letter?

1681 A. From a letter-press copy of that letter which I made before I sent it.

Q. 3438. Can you produce the letter-press copy from which the record was made?

A. I cannot; I gave it to Mr. Sawyer, the secretary of the Electro-Dynamic Light Co., to record it in the minute book, take care of it, and file it with the papers of the Electro-Dynamic Light Co.

Q. 3439. Did you compare the record of that letter in the minute book with the letter-press copy you have mentioned, and do you know of your own knowledge that the record of the letter in the minute book is a true copy?

A. I did so compare it with the record in the minute book with

Mr. Wm. E. Sawyer, the secretary, and I believe it to be a true copy of the letter I sent to Mr. Lowrey, and think I know it is.

Counsel for complainant calls on defendant's counsel to produce the original of this letter, to be offered in evidence.

Mr. Lowrey being present, says that counsel for defendant has never received any such letter, that in his personal character Mr. Lowrey will examine his file of personal letters deemed to be of sufficient importance to be preserved, and if such a letter is found he will produce it. That he has no present recollection of receiving such a letter.

The record of letter referred to as found in the minute book of the Electro-Dynamic Light Co. is offered in evidence as "Complainant's Exhibit Man's Letter to Lowery of October 31st, 1878, March 29, 1889," with the understanding on behalf of complainant's counsel, that if the original is produced it may be substituted for the copy found in the minute book.

Q. 3440. Did you have any personal interviews with Mr. Lowrey regarding the subject-matter of these letters? If so, please to state what was said at such interviews, as you recollect it.

1682 A. I had several interviews with Mr. Lowrey prior to his going at my invitation to No. 94 Walker street, in which I endeavored to impress upon him my views that it would be advantageous to both the Edison people and the Electro-Dynamic Light Co. that their interests should be united and their inventions worked together, rather than to be antagonistic or rival interests, this, as a business proposition, addressed to business men. I myself at the time believed that we were very far in advance of Mr. Edison in incandescent electric lighting, as I saw his attempts and experiments published in the periodicals of the day, and as I had heard of them from others, and I expressed this belief to Mr. Lowrey as an inducement to the Edison people to unite with us. On the day of his visit to 94 Walker street Mr. Lowrey and I went from that place, according to my recollection, to my office, No. 3 Mercer street. We there had a conversation, in which Mr. Lowrey, in substance, expressed himself pleased with what he had seen and that it was more or better, or both, than he had anticipated, and promised to confer with other people interested in the Edison invention or inventions, and I think we canvassed in some measure, the appointment of committees on the part of the Electro-Dynamic Light Co. on the one side, and on the part of the Edison electric light people on the other side, or Mr. Lowrey for them, to confer together in regard to the propriety of a union of interests and the basis of a union, if any should be deemed practicable, or advisable, and Mr. Lowrey at this interview, I think, promised to further confer with me or write me.

And on receipt of his letter on the 31st of October, 1878, on the same day the Electro-Dynamic Light Co., at a meeting of its trustees, did appoint such a committee of whom I was one, and I verbally advised Mr. Lowrey of their appointment, and some further conversation was had between us of a like character to that that had gone before. I think this was the same day or the day following the 31st of October, 1878. I do not think I had any further 1683 conference with Mr. Lowrey, after the receipt of his letter dated November 2, 1878, which was an utter surprise to me, until long afterwards at several times when I casually met him, and simply possibly referred to the subject-matter. I think in the summer of 1880, after the organization of the Eastern Electric Manufacturing Company, I again brought up the subject-matter of either a union of the interests of the Electro-Dynamic Light Co. and the Edison Electric Light Co., or the sale of the patents and inventions of the Electro-Dynamic Light Co. to the Edison Electric Light Co. with Mr. Lowrey, but nothing was accomplished and the matter was dropped.

Adjourned one hour for lunch, to resume at 2 p. m.

Resumed at 2 p. m.

Witness continues:

Several persons indirectly approached me and the other directors of the Electro-Dynamic Light Co. to know whether the patents and inventions belonging to that company would be sold. It was after conference between myself and other trustees thought best that I should call on Mr. Lowrey in regard to the matter, as it was supposed or understood that these inquiries came from or were instigated by the Edison Company. I accordingly called on Mr. Lowrey in regard to the matter, referred to previous attempts at negotiations, and perhaps to the inquiries that had been made, and asked him whether the Edison people desired to enter into negotiations. He told me, as near as I can recollect, that he was not advised of any such thing, that it was hardly in his province then, that other people had charge of such matters and advised me, I think, to see Mr. Wright, of Drexel, Morgan & Co. This, I think, is the substance of what took place in the summer of 1880, as I recollect the time of it.

Q. 3441. Referring now to the correspondence and interviews with Mr. Lowrey in the fall of 1878, when did such interviews and correspondence terminate?

1684 A. Immediately after my receipt of his letter of November 2, 1878, so far as any conference was concerned, or interviews. The last correspondence, so far as I know or recollect, was his letter to me dated November 6, 1878.

Q. 3442. Was he then one of the counsel of the Edison Electric Light Co.?

A. I only know from his being a lawyer and from being referred to him, and by my interviews and correspondence with him. I supposed him to be so.

Q. 3443. How often did Mr. Lowrey call at the shop of the Electro-Dynamic Light Co. on the corner of Elm and Walker streets in the fall of 1878?

A. I only remember the one occasion to which I have testified, and which is referred to in the correspondence between us.

Q. 3444. Was that occasion in the daytime or in the evening, and were your lamps exhibited to him at that time?

A. My recollection is that it was in the daytime, and that the room was darkened by putting up movable shutters which we had at the windows, that several lamps were lighted up and turned off to show that one could be turned off without affecting the others, and turned down to less incandescence by means of switches to show that one lamp or more could be run at one incandescence while the others were running at a different incandescence, the lamps individually giving such light as was desired within their limits of luminosity; that the dynamo-electric machine that was running the lamps was shown to him, and the switch or switches by which the lamps were turned off and their luminosity governed.

Q. 3445. State, if you recollect, how many lamps were in circuit at that time?

A. I cannot state further than that I remember that several were lighted at the same time in order to show that one could be turned off or reduced in brilliancy without affecting the others.

1685 Q. 3446. What was the duration of Mr. Lowrey's visit at that time, as you recollect it?

A. I could not undertake to state that at this length of time, definitely. My impression would be from half an hour to an hour.

Q. 3447. Do you know anything of a visit of Mr. Lowrey to the works of the Electro-Dynamic Light Co., corner of Walker and Elm streets, in the spring of 1879? If so, please to state what knowledge or information you have about such visit?

A. About a week or ten days after the 20th of March, 1879, I knew of Mr. Sawyer having invited gentlemen from, or representing the Edison Company, to witness an exhibition at evening of our electric lights and apparatus at that place. I was not present at the exhibition inside the building, but saw the illumination of the building, or our rooms, as I passed by there, and I heard that the Edison people were there that evening, and that Mr. Lowrey was among them. I do not know it personally, except by reputation.

Q. 3448. This exhibition made by Mr. Sawyer at that shop, mentioned in your last answer, was after you discontinued to work with him, as I understand you, and after you had closed the shop, so far as the Electro-Dynamic Light Co. was concerned.

A. It was, and also after Mr. Sawyer had made a proposition to the Electro-Dynamic Light Co. to interest other people, which had been accepted, at least provisionally by the Electro-Dynamic Light Co., and the exhibition was made by Mr. Sawyer, as I understood, in order to interest other people in accordance with his proposition.

Q. 3449. As I understand you, you had no personal knowledge of this exhibition beyond what you have stated, or of the causes which led to it. Am I right in my understanding?

A. Not quite. I knew that the exhibition was to be made: I knew the object of the exhibition, and knew that it was
1686 made. I knew the object of it through Mr. Sawyer, and I

think, Mr. Church. I have already stated in my testimony that it was made by Mr. Sawyer in pursuance of an attempt to carry out his proposition before then made to the Electro-Dynamic Light Co. to interest other people.

Counsel for defendant, Mr. Lowrey, calls the attention of the counsel for complainant to the intention already expressed by Mr. Lowrey to limit, so far as is possible, the future cross-examination of this witness, in order that the already overburdened record may be limited as far as is practicable. He also calls attention of counsel for complainant and of the court to the character of the testimony, as being called out and permitted from the witness, it being a very large part hearsay and inference from assumed facts which would seem to force upon counsel for defendant a prolonged cross-examination to separate that which is really material and competent from that which is not so, and lest counsel for complainant may be misled and also the witness by the absence of any present objections, under the arrangements heretofore made, he now calls attention to the tendency of the testimony, both questions and answers, to spread beyond suitable limits, and asks counsel to restrain it. Mr. Lowrey makes this statement not in any way imputing either to witness or counsel a purpose of this sort and merely to guard them against what must necessarily lead to the statement of broad objections and to the unnecessary prolongation of cross-examination.

Counsel for complainant says in reply that he has finished his examination of the witness upon the topics upon which he has been last examined and that he has asked him no more questions than he thought were fairly necessary to corroborate the testimony of other witnesses that he proposes to call.

Q. 3450. Please state how the Consolidated Electric Light Company came to be formed?

A. Sawyer having fallen out with Messrs. Wallace, re-
1687 turned to New York in the month of September, 1879, in a
very antagonistic frame of mind and demanded a license under the patents to go on and manufacture, although he knew that Messrs. Wallace & Sons held an exclusive license from the company. This was refused him. Thereafter he devoted himself to active antagonism to the Electro-Dynamic Company and its interest in every way.

In the early part of 1880 he succeeded in organizing an opposition company entitled the Eastern Electric Manufacturing Company, and in the meantime he devoted himself to writing articles to the newspapers, which he told me were intended to injure the Electro-Dynamic Light Company and myself, and to belittle the work that we had done, and in this connection he wrote a book entitled "Sawyer on Electric Lighting." Mr. Edwin Myers was taken sick in the fall of 1879, and after a lingering illness died. There was no other person acquainted with the manufacture except myself, and I was too absorbed in other business, which I could not leave to attend to it. The hostile activity of Mr. Sawyer and the Eastern Electric

Manufacturing Company, which he had organized, continued, Sawyer refusing to unite in applications for patents, reissues and in the prosecution of interference proceedings, and otherwise injuring us, until finally, in order to put an end to the matter, an agreement was made by which the patents and inventions belonging to the Electro-Dynamic Light Company were in the spring of 1881, sold and conveyed to the Eastern Electric Manufacturing Company. Sawyer agreed that he would thereafter cease his hostility and work actively for the interest of the patents. This he did for a little while. He soon became hostile to the Eastern Electric Manufacturing Co. His habits were so bad that no one could work with him, and he had parted with, hypothecated and sold all his interest in the company. Then, in order to get the patents actively at work, a consolidation was made with the American Electric Light 1688 Co., which agreed to furnish capital and go on with the work, and the Consolidated Electric Light Co. was the result of this union, which was effected in the fall of 1882, and the business of manufacturing and selling incandescent electric lamps under the patents of Sawyer and Man, has been actively carried on from that date.

Adjourned till Saturday, the 30th inst., at 11 a. m.

SATURDAY, *March 30th*, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant, and Mr. Lowrey for defendant, and the examination of Mr. MAN proceeded as follows:

Q. 3451. Referring again to the testimony of Mr. Wm. Sharp, he says in answer to question 50 as to machinery, that you had at Walker street:

"They had a small dynamo, a lathe, a grindstone, a boiler and engine. I might say there were two vices in there."

Is that a description of all the machinery you had at that place?

A. It is not.

Q. 3452. How is it deficient?

A. There was all the time two dynamos, a large one of the largest size then built by Arnoux & Hochhausen, and a small one built by them, and part of the time three or more dynamos. There were two lathes there, a chemical bench, permanently fitted up, a water exhaust, permanently fitted up, mercury exhausts, barometers and mercurial g*ua*ges, permanently fitted up to the wall above the chemical bench or table, galvanometers, on the same bench, switches and other electrical apparatus, and a very complete and extensive chemical apparatus, a set or partial set of carpenters' tools, 1689 and tools for doing special work, turning tools and bench tools of all kinds, a steam engine and boiler, and on the partition in the back room an electrical meter and a number of switches, a locked cupboard at the south end of the workmen's bench, to the right of Mr. Wm. Sawyer's place, filled with work and apparatus and materials, and at the other end of the bench a cupboard with a cloth cover at the left of where Mr. Sharp worked, filled with chemical apparatus and materials. In the front room there was a large table in the centre. At the south side, between the windows, a table filled with testing and measuring apparatus, with a set of galvanic batteries underneath it; opposite that, on the other side of the room, a large screen; on the north side, next the hall, was Mr. Sawyer's private desk and revolving chair, and there was a set, I think, of half a dozen common chairs in the room. There was on the centre table a variety of testing apparatus. There was a stand for a camera and photometer, used for both, lamps put up on brackets on all sides of the front room, arrangements on the chandelier for lamps, a movable lamp on the centre table connected to the chandelier; in the back room brackets at different points for setting up lamps, apparatus for treating carbons in both oil and gas, and a great variety of things I can't enumerate. I have omitted several switches in the front room and several in the back room, and electric circuits running in both rooms, and electrical resistances, rheostats fastened to the walls and partitions. One of the lathes was a large or medium sized lathe, intended to be run by power, and adapted to doing a great variety of work. It also had a pedal that could be attached, but was too heavy to be run practically by foot. The other lathe was quite small and adapted only to turning. It was a foot lathe.

Q. 3453. What do you mean when you say you had a "water exhaust" in the shop? Please to describe it, stating its general construction and mode of operation?

1690 A. It consisted of a lead pipe, thirty six or eight feet long, run from the roof of the building down through the light or air shaft at the northwest corner, with an enlarged air chamber at the top. Through the top of the air chamber, soldered in, entered the water pipe, connected on our floor to the Croton water system, with a faucet for turning the water on or off. This pipe was diminished in size in the air chamber at its lower end, and nearly entered the waste pipe connected with the lower end of the air chamber, of which I have spoken. The waste pipe at its lower end was turned up and had an air-tight reservoir or trap, large enough to hold water enough to fill the pipe with water as high as it would rise with atmospheric pressure. From the upper air chamber at its upper end ran a small lead pipe, soldered into the air chamber, which passed down to our floor in the light-hole, and from thence through the brick wall, and was carried on the north wall of the building to a point just above the chemical table, where it ended with a small stop-cock and screw-nipple, by which to connect it with the exhaust system of the lamps. This is a general description only.

Q. 3454. Was this apparatus used to exhaust the lamp chamber of its air?

A. It was.

Q. 3455. What degree of exhaustion in your last chamber was obtainable by this apparatus?

A. Sometimes more and sometimes less, according to the flow of water in the Croton water *water* system. When the flow of water was good we could obtain by it an exhaust whose pressure was substantially equal to the tension of water vapor at ordinary normal temperature of the atmosphere, or about that. It was such an exhaust that the height*h* of the mercury in the g*ua*ge which measured it could hardly be distinguished from the height*h* of the mercury in the barometer standing beside the mercury gauge.

1691 Q. 3456. What other, if any, apparatus did you use in your shop at the corner of Walker and Elm streets, for the purpose of exhausting your lamps?

A. The ordinary mercury exhaust, on the principle of the Bunsen or Geissler pump, worked by filling a chamber with mercury, driving out the air, shutting the stop-cock by which the air escaped, opening a stop-cock to the space desired to be exhausted, and then allowing the mercury which filled the chamber to escape through a vertical tube of the length of about thirty-six inches, and repeating the operation. I also had a Sprengle pump. I do not now remember or recall whether it was used there or not.

Q. 3457. Mr. Sharp in his deposition testifies as follows:

(Counsel reads from question 213 of his examination-in-chief to 216.)

Please state who made that lamp. I mean the lamp of figure 49 in Sawyer's book.

A. Referring now only to the spiral leading-in-conductors of that lamp, made of concentric spiral tubes, for the first lamp of this pattern Mr. Sharp turned from wood the form for bending the tubes constituting the conductors, and he and I bent them and fitted them together and fastened them to a diaphragm and a lamp base at his place in Brooklyn, in the month of April, 1878, according to the best of my recollection. I have a distinct recollection of the work and of the difficulties we met with in executing it and keeping and fastening the conductors so that they would not by the least movement touch each other, and so, short circuit the lamp. It is proper, however, to remark in justice to Mr. Sharp, that I did not tell him and he did not know what he was doing or what the apparatus was for, and that the holders above the diaphragm were not put on by him, but were at 43 Centre street, and that this apparatus was separate and distinct from the two lamps to which he has referred in his testimony and was made before either of those to which he referred.

1692 Q. 3458. Referring to the lamp marked the horseshoe lamp, figure 52 in the Sawyer book, what kind of carbons were used in that lamp?

A. Mostly, if not entirely, carbons made from wood and paper. It may be that some few lamps were set up of this form with circular discs or rings turned from sheet French carbon or sheets of gas-retort carbon; but I do not think so in lamps of this size, or diameter of lamp chamber.

Q. 3459. The carbon burner of this lamp as it appears by this drawing in Sawyer's book, appears to be thicker at its junction with the holders than in the center. How do you account for that appearance?

A. We made carbons that were so, but this may be in the illustration, only a fault in drawing or representation, or it may represent a flat twisted-paper carbon, of which we used some.

Adjourned for lunch.

Resumed after lunch.

Q. 3460. What do you mean by a flat twisted-paper carbon? Please to take a piece of paper, cut it and illustrate what you mean.

Witness takes a piece of paper, cuts it, and says: "I bend it in the form of a loop and twist it, at the same time so that the plane of the paper at its two ends will be the same, so as to be held in the two holders flatwise, as illustrated."

Q. 3461. Do you mean by that that the ends of the conductor when twisted as you have illustrated will show the breadth of the conductor, and the top of the arch will show the thickness of the paper?

A. Yes, that is it.

Q. 3462. And did you make such conductors as long as this shown in figure 52 of Sawyer's book?

A. Yes, I think so, and longer.

Q. 3463. Referring now to the carbons made of willow
1693 about which you have testified; of what kind of willow did
you make such carbons?

A. We made them from willow osiers—basket willow—which I got, and from willow twigs, from weeping willow.

Q. 3464. What part of the weeping willow did you use?

A. The pendulous twigs of the growth of the year or year previous, both, the long sweeping branches or twigs of the weeping willow.

Q. 3465. How did you prepare them for carbonization?

A. Selecting them, removing the bark, some of them that were fine enough, boring out the pith, bending them and carbonizing them whole, after being bent, some of them carbonizing in straight pencils without being bent, with and without the pith removed in both cases. Some of them we split up, shaped them to the size we wanted, then bent them and carbonized them or carbonized them in straight pencils. The same with regard to the osier or basket willow, except that none of these were small enough to form conductors and so had to be split and shaped to size.

Q. 3466. Where your carbons proved defective how long would it take to take the lamp apart and put in a new carbon?

A. Where one lamp alone was taken, perhaps ten minutes. If more were taken in a batch, a less average time, but if the lamp required any cleaning it would take longer.

Q. 3467. In that case, give the maximum time it would take in the hands of a fairly skillful man?

A. Mr. Sawyer was accustomed to say, and I think he was correct, that he could take down and set up from ten to a dozen lamps an hour, putting new carbons in them.

1694 Q. 3468. How many lamps and parts of lamps did Mr. Sharp make for you before he went into the employ of Sawyer & Man?

A. That would be impossible to tell, as to the parts, because he worked at a great many parts of different lamps and made other parts for lamps which we already had, to change their internal work. I do not now remember but two lamps that were made complete at his shop in Brooklyn, or at most three, and those did not have the carbon conductors in them. The two that he has mentioned and the concentric spiral lamp, which I have mentioned; I do not think the holders for the conductor were in this last-mentioned lamp, but they may have been. I don't think he put them in, but I don't know. The best of my recollection is that he did not.

Q. 3469. Mr. Sharp testifies in cross-questions and answers 567 to 568, inclusive, that there were no galvanic batteries in the office room, corner of Walker and Elm streets. What is your recollection about that?

A. There certainly were, as I have testified. I have them now and can produce them.

Q. 3470. Redirect question 603 of Sharp is as follows:

"At your home or shop in Brooklyn did you ever bore several dozen glass base plates for Mr. Man or Mr. Sawyer?

"A. I have a slight recollection of drilling one or two holes, but no such quantity as one or two dozen."

What is your recollection as to that?

A. My recollection of the subject-matter is that before we got molds for making the holes in the glass base plates of the lamps at the same time that they were blown, that I had the holes bored in them by a lapidary in Ann street, New York; that I took one of those over to Mr. Sharp's place to have him fit the tubular binding screws to it; that something happened to it, and that I proposed to get another one bored; that Mr. Sharp told me that that was 1695 unnecessary, as he could drill them. I asked him how he would do it, and he said with an ordinary steel drill. I had never heard of such a thing before and it was new to me, and I asked him to show me how he did it. He got a piece of glass and took a steel drill, and after hardening it, drilled the glass with it; but in doing so the inside or further part of the glass where the drill passed through last was bursted out around the edges; that to prevent this we got a tube and after drilling with the steel drill until the point of the drill came through the glass we used the tube with emery and water or turpentine, and succeeded in making smooth holes through the glass. We were having at the same time these glass base plates made at the glass factory in Brooklyn, and finding that Mr. Sharp could drill them, as I was returning home, I called at the glass factory, got my pocket full of the glass bases, took them to Mr. Sharp, and he did drill them. I wish to add that in none of these cases did Mr. Sharp know what the things he was doing were for, at least, I did not tell him. I mean during the period while we were at 43 Centre street, except in the one case some time after his work was done, I told him it was for an electric lamp.

Q. 3471. What other interferences did you have with your patents other than your interference with Mr. Edison?

A. We had an interference with Maxim & Keith, declared March 4th, 1879. That interference was dissolved March 2nd, 1880. We had also an interference with Brush & Fuller, which was declared April 29th, 1879, and dissolved January 5th, 1880. We had also an interference with Hiram S. Maxim, declared August 16th, 1880, dissolved July 10th, 1883. We had also an interference with Edward Weston, declared October 1st, 1881, and decided September 24th, 1884. The subject-matter of the first interference was treating and making carbons for incandescent electric lighting electrically in an atmosphere of hydrocarbon. The subject-matter of the
1696 second interference was an electrical switch for controlling
the currents in electric lighting. The subject-matter of the third interference was an electric regulator for governing currents in electric lighting. The subject-matter of the fourth interference was for the treatment of carbons for incandescent electric lighting in a hydrocarbon bath or atmosphere.

The complainant having called Albon Man, and offered in evidence his printed testimony and accompanying exhibits taken in the case of The Consolidated Electric Light Co. *vs.* The Edison Electric Light Company, pending in the circuit court of the United States, in the southern district of New York, and in like manner, his printed testimony and exhibits taken in the interference proceedings between Sawyer and Man and Thomas A. Edison, and it being understood that said Man is to be produced as a witness in this case to be subject to further cross-examination upon the testimony in the said two other cases, should defendant desire it after reasonable opportunity to examine the printed testimony now offered, the defendant now consents to the introduction of said testimony and exhibits without other objection than such as already appear upon the records now introduced.

Counsel for defendant notifies counsel for complainant that defendant now offers to enter into the same stipulation in respect to the testimony of any witness for Sawyer and Man in the interference above referred to, who shall be produced by the complainant for further cross-examination, as Mr. Man has been.

(COUNSEL'S NOTE: The testimony of Albon Man taken in the interference case referred to above, is printed in volume 3 of this record as follows: First deposition, pages 102–125; second deposition, pages 205–210; third deposition, pages 572–600.)

Adjourned till Monday, April 1st, at 3 p. m.

1697 TUESDAY, *April 2d*, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and Mr. Lowrey for defendant, and the examination of Mr. MAX was continued as follows:

Q. 3472. State, if you please, who did the carbonizing at your shop at the corner of Walker and Elm streets?

A. Mr. Edwin L. Myers, principally under my direction. I did some, and Mr. William E. Sawyer, I think, did a little.

Q. 3473. Please to state if you recollect of making any lamps at your shop at Walker and Elm streets of the form substantially shown by the sketch now shown you.

A. I do.

Q. 3474. State if you recollect how many of such lamps were made.

A. I cannot be precise as to numbers at this date, of that exact form of globe; my best recollection, I would say, about a dozen.

Q. 3475. Please to state how they came to be made, and state if you have any parts of such lamps that you can produce.

A. We had blown while we were at the corner of Centre and Howard streets a number of sizes of globes, as many, I think, as six or seven different sizes in diameter and of great variety and length. They were mostly straight tubes, with a flange at the lower end like test tubes in shape, but some of them had round bulbs blown on the closed end of the tube. The smallest size of these globes or lamp chambers had an internal diameter of about one inch and their length was from four to six inches; we had them set up at about the time of our going to Walker and Elm streets, or soon
1698 afterwards, a batch of something like a dozen lamps. Some of these had little round bulbs at the top. I did not like the shape of them. It was not pretty and after trying to draw something satisfactory to myself I called upon my friend, James McDonough, an artist and designer, and now president of the American Bank Note Company, and he drew for me the design of the tulip-shaped bulb shown in the drawing which I have produced and which I made. I took the drawing to Mr. Hahn, glass-worker, in North William street, and about a dozen of the straight tubes of the internal diameter of about an inch and the length of about four to six inches, already ground and fitted to the glass discs or bases of the lamps already used, and on which the works were set up, and the workman at Mr. Hahn's (they called the workman "Gus." I think his name was August Wedekind) blew the upper part of the tubes into the tulip-shaped form of bulbs, and I took them back to our shop in Walker street and had the lamps set up in them, and they were run there. I am unable to produce any parts of these lamps except the short spiral conductors, which I now produce, and do not know what became of them. I only know we had them and run them. I produce a piece of soapstone from which the diaphragms of these little lamps were turned, showing the diameter of the diaphragm of these small lamps in its circular part. I may have some of these diaphragms and might be able to produce them, but I have not found them yet. My attention was called to this matter in regard to this little

lamp by the testimony of my daughter, Mrs. Ives, yesterday. I have spoken in my testimony of the small lamps and lamps with bulbs, but not those, if I recollect right, of this particular form.

Drawing and conductors and soapstone produced by witness, offered in evidence and marked "Complainant's Exhibits Man Drawing of Tulip-shaped Lamp and Exhibit Conductor of Tulip-shaped Lamp and Soapstone or Disc of Tulip-shaped Lamp, all of April 2, 1889."

(Here follows diagram marked p. 1699.)

1700 Q. 3476. Please to take the sketch produced by you and mark its several parts with letters or figures of reference, and describe its several parts on the record.

A. No. 1 is globe of lamp with flange; No. 2, glass base; No. 3, binding screws and cups with stop-cock; No. 4, binding screws of clamping rings; No. 5, clamping rings; No. 6, upright carbon clamps for incandescent conductor; No. 7, incandescent conductor; No. 8, copper conductors corrugated; No. 9, diaphra-m soapstone.

Q. 3477. What kind of carbons were used in those lamps?

A. Mostly small circular rings or loops. I think one or two of them were fitted up for straight pencils.

Q. 3478. What were they made of?

A. Carbonized wood and paper usually.

Q. 3479. Cut to size before carbonization?

A. Yes, sized and shaped before carbonization.

Q. 3480. Who, if any one of your family, did you take to see these lamps?

A. Early in the fall of 1878 I took some friends, Mr. and Mrs. Greenough, who were visiting at my house, my daughter Ida, and my sister-in-law, Alice Watkins (the two ladies who testified in my presence here yesterday), over to our shop in Walker street, and showed them our lamps, as the ladies testified yesterday. This was soon after our going to Walker street. I do not mean to testify that this kind of lamps was what was shown to them, for I do not remember, but I do wish to be understood that at that time we had the small lamps of this kind, and also many other kinds of lamps.

Q. 3481. When did you make the sketch which you have produced?

A. I made it in pencil mark last evening, finished and inked it this morning and just now.

Q. 3482. Does the sketch represent the lamp as made by you in 1878 as accurately as you can now recollect it?

1701 A. It does as accurately as I can recollect. It is not drawn to scale, except approximately, by the eye. It does correctly represent the general appearance of the lamp.

Q. 3483. Do your daughter and Miss Watkins identify it as of the form of globe which they saw and about which they testified yesterday?

A. They do, both of them.

Cross-examination by Mr. LOWREY:

X Q. 3484. In the letter produced by you referred to in your 3419th interrogatory, purported to be signed by Mr. Lowrey, dated October 30th, 1878, there appears to be a reference to an article in the morning paper. I hand to you a copy of an article from the New York Times of October 30, and ask you whether you understand that that is the article referred to.

It is understood that the copy referred to in the question is to be compared with the original and corrected by the examiner, and when so corrected to be treated as original.

A. Several of the newspapers contained more or less extended notices of our lights, I think on the morning of October 30th; of course I cannot say what one Mr. Lowrey referred to in that letter; I think the New York Times published an article that morning; my recollection is that it has already been introduced in evidence; I may be wrong.

X Q. 3485. Have you now read the Times article, and do you find the statements therein contained substantially correct?

A. Substantially correct, only as a newspaper reporter would write out an account of what he saw.

X Q. 3486. Do you see anything in that article to which you would wish to call attention as being incorrect in substance?

A. The reporter assumes, perhaps, in the article that he knew 1702 all that Sawyer and Man had done. I think he gives a pretty correct description, so far as it goes, of what he saw.

X Q. 3487. Can you tell from whom this or other reporters about that time obtained this information, whether from you or Mr. Sawyer, or both?

A. The reporters had been running there to our shop. We had to stop our lathe to run the dynamos. We would just simply show them the light and get rid of them, to go on with our work, not only reporters but other people. I think Mr. Sawyer sent notice to all the papers to have them all come at once, and they did come and the lights were shown to them. I was present part of the time. While I was there they asked questions of Mr. Sawyer and of myself, some of which we answered and some of which we did not answer, and the next morning these articles came out in the papers.

X Q. 3488. Mr. Man, I call your attention to cross-interrogatory 5, addressed to Franklin L. Pope, in this case and hand you at the same time an electric lamp bearing the stamp of Sawyer-Man upon the metal socket, and will ask you while examining the lamp to listen to the description of a lamp which I take from the interrogatory above referred to, and will ask you to say whether that is a correct description of the structure and mode of making of the lamp now in your hand?

"The lamp consists of what may be called two parts, one part consisting of an enclosing globe or bulb made entirely of glass; the other part consisting of an incandescing conductor and wires to which it is attached in the interior glass portion. The inside part

contains a filament of carbon first united mechanically and then electroplated to two small platinum wires. These platinum wires pass through the glass, the glass being sealed around the wires by the fusion of the glass. The inside part is then inserted in the glass bulb and the seal is made by hermetically sealing the glass
1703 bulb and the glass of the inside part by fusion of the glass; the lamp, as an entirety, being now complete, the air is exhausted from the top of the bulb, where the 'tit' is, and which previously was an open tube, and, after being exhausted, a hermetical seal is made at this point by the fusion of the glass."

A. In regard to the lamp you hand me, the description is a substantially correct one, except in particulars in which I am not able to judge from the mere appearance of the lamp, to wit: The attachment of the carbon conductor to the leading-in wires or conductors, and to the atmosphere of the lamp, of which I can know nothing by appearance. The description is not accurate as to the manner in which the leading-in conductors are passed into the lamp, nor in the support of those conductors.

X Q. 3489. Are those the only divergences of substantial importance that you note?

A. Yes.

X Q. 3490. State if you know by whom that lamp was manufactured, and for what purpose.

A. I do not know, except for the purpose, apparently, of electric lighting.

X Q. 3491. Do you not recognize that as a lamp of the Consolidated Company, made under the Sawyer and Man patents?

A. No; not of the Consolidated Company or the Sawyer and Man Company. I do not wish to be understood that it was not made by them, but that I do not recognize it. The particular part of it that I do not recognize is the attachment of the conductor to the leading-in wires.

X Q. 3492. Does this lamp conform in all essential particulars to the principles of construction under the Sawyer and Man patents with which you are familiar?

A. I think it contains many of the things which we patented, or substitutes or equivalents for them.

1704 The lamp is offered in evidence and marked "Defendant's Exhibit Sawyer & Man Electric Co.'s Lamp No. 1, April. 2, 1889."

X Q. 3493. I hand you now another example of a lamp, and ask you to state what that is, if you know.

A. That is, I think, a Sawyer & Man lamp, made by the same company.

Said lamp put in evidence, and marked "Defendant's Exhibit Sawyer & Man Electric Co.'s Lamp No. 2, April 2, 1889."

X Q. 3494. Tell me, if you know, whether lamps of the type of either of these exhibits are in general use in connection with the electric lighting system of the complainant.

A. I know only that many lamps similar in general appearance to these, without going into details as to construction, are in use all over the country, and I understand them to be put out under the general direction of the complainant, or its licensees.

X Q. 3495. I now show you a lamp, which has been put in evidence in the case of The Consolidated Electric Light Co. *vs.* The Edison Electric Light Co. in the southern district of New York, and marked "Complainant's Exhibit No. 21, Edison's Incandescent Electric Light, Timothy Griffeth, examiner, October 9, 1886," and which is understood to be identical with "Exhibit Defendant's Lamp" and referred to in interrogatory 4, to Franklin L. Pope herein, and will ask you to compare it with Exhibits 1 and 2, referred to in the last interrogatory, and say in what essential particulars, if any, the latter differs from the two former lamps? I do not refer to non-essential mechanical details, but only to such particulars as affect the character of the respective lamps, as consisting chiefly of fibrous, arc-shaped incandescing conductors in chambers wholly of glass and hermetically sealed.

1705 A. You wish me to leave out then all the mounting of the lamps and consider them simply as to the glass leading-in-conductors, atmosphere and carbon?

Counsel says "yes."

Witness continues:

The construction of the three lamps is very similar; a slight difference in the shapes of the globes, a difference in the support of the leading-in conductors and the carbon conductor; a difference between No. 2 exhibit and the Edison lamp in the attachment of the leading-in wires to the carbon conductor. I cannot tell how the attachment between the leading-in conductors and the carbon conductor is made in Sawyer-Man lamp, No. 1 exhibit. In the Edison lamp it is evidently electroplated with copper. In the Sawyer-Man lamp I do not know that I have ever seen one like it and don't know how it is connected.

X Q. 3496. What appears to be the material of the carbon in each case?

A. Carbonized fibrous material.

X Q. 3497. By what do you judge that it is fibrous material?

A. I know of no way by which such conductors as these appear to be can be made except from fibrous material. It is proper to remark that all the conductors appear to my eye to have been treated in some manner by deposit of carbon upon them.

X Q. 3498. From your experience in the making and inspection of lamps, do you doubt that these carbons are as stated in the question to Mr. Pope and to yourself, made from bamboo fibre?

A. I have no knowledge whether from bamboo fibre or some other fibre. I simply know that bamboo fibre would make such carbons, and if asked should say that they look like carbons made from bamboo fibre.

X Q. 3499. You have spoken in your recent re-examination-in-

chief of refitting and refilling and cleaning of lamps. Will
1706 you explain in a general way the occasions which occurred
in your experience, or were expected to occur in the use of
your lamps, for refitting or refilling a lamp, and how this would be
done?

A. All our lamps, while Mr. Sawyer and I were working together, were made so as to be readily taken apart, so that anything could be readily done to the interior work of the lamps, such as substituting carbon conductors, or restoring vitiated atmosphere or an atmosphere not suitable to the incandescent lamp. The word "filling," as used by me, covers exhaustion of the atmosphere filling with an inert gas, repeating the process of exhaustion and filling, heating up the walls of the lamp and heating up the interior of the lamp, and especially the incandescent conductor by an electric current, and finally leaving the lamp sealed up with an atmosphere of inert gas, or a vacuum of such gas. Perhaps it would be better to say, such a gas at different pressures from a little below atmospheric pressure to a substantial vacuum. The method of doing this, while Mr. Sawyer and I were working together, was to take out the screws holding the binding rings together, remove the sealing, open the stop-cocks to let the air in, in case there was an attenuated atmosphere in the lamps, then remove the glass plate to which was attached all the interior works of the lamp. If any purifying were required, clean the parts as attached to the glass base plate; if the carbon were a straight-pencil carbon, remove it, or any remains of it, and put another in its place, wash out the globe with alcohol, or ether or both; put the interior works of the lamp which were on or attached to the glass base plate into the globe proper, and screw the two parts together with the binding screws and rings. The refilling was done in the same manner as the original filling, all the lamps requiring to be filled or exhausted being connected together in one batch, and all done together. By refitting, I mean this, that we were frequently and often changing
the carbon-holders and their adjustments with the carbon
1707 incandescing conductor, and these changes I call refitting.
In the straight-pencil lamps the method of holding them in
the carbon clamps or holders was very frequently changed. This I called refitting. Again, the parts of the lamp above the diaphragm (which diaphragm is represented in the exhibits you have presented me to-day, by the glass support of the leading-in conductors) were frequently changed to use carbons for incandescent conductors of different shapes, or lengths, or sizes, such as the change from straight pencils to arch-shaped carbons of greater or less diameter, or the reverse, from arch-shaped to straight pencils of greater or less length. The occasion for doing this was to make a lamp which in all its parts, except the incandescent carbon conductor, would be permanent, and to make a lamp of such construction that a new incandescent conductor could be substituted in the lamp, which itself was permanent. The further occasion in our practice for the thing was like this: The testing of contacts between the holders and the incandescent conductor, the testing of the atmos-

phere of the lamp and the durability of the incandescent conductors of different shapes, forms and sizes, and of different methods of attachment to their holders. We almost continually took down good lamps to examine microscopically the incandescent carbons. We also frequently took down good lamps because, by reason of the formation of electric arcs at the points of contact, we found that such contact had not been made perfect electrically. We observed these arcs when the lamps were set up by means of a camera and screen by which a picture of the carbon while incandescent was thrown upon the screen of very large size, and when we found the least appearance of such an arc or defect, or the least appearance of the consumption of the carbon, or of defect in the carbon, such as unequal resistance at different parts of it, we usually took the lamps down, refitted or refilled them, or both, or sometimes ran them to light our shops, but not for exhibition In the
1708 straight-pencil lamps some of these lasted a very long time. Many of them were good lamps, but we thought them not reliable.

X Q. 3500. I understand then, Mr. Man, that you contemplated that in use the illuminating part or carbon might be subjected to injury or destruction, and the design of the lamp was to allow renewal or repairs without sacrificing the lamp chamber itself or any of the uninjured parts of the structure?

A. Yes, we did so contemplate and we did not know as we do now, the average life of the carbon conductor, and we thought it desirable to make a lamp in which a new carbon conductor could be substituted for one that should give out for any cause at any time.

X Q. 3501. You understand that we are speaking of the lamp of the patent in suit?

A. I mean the lamps made by Mr. Sawyer and myself, one of which is illustrated in the drawings of the patent in suit.

X Q. 3502. Look at figure 2, attached to the patent in suit, and say whether that is intended to illustrate a lamp upon the plan and to attain the purposes which you have explained.

A. The illustration, figure 2, is from the drawing accompanying the application for the patent in suit, and was made from an actual lamp given to the draughtsman from which to make it, which was one of the lamps made by Mr. Sawyer and myself, while at 94 Walker street, in our work for making a practical incandescent lamp, and is one of the plans used by us for that purpose. It is a lamp that may be readily taken apart and set up again, as I have described.

X Q. 3503. Is that lamp, as thus designed and constructed within, according to your understanding, the second and fourth claims of the patent in suit?

A. First, as to the second claim: I answer, yes, if the incandescent conductor is made of carbonized, fibrous material. Second: As to the fourth claim, I answer, yes.

1709 X Q. 3504. Please look again at Exhibits 1 and 2 of to-day and 21 of the New York case, referred to in a previous answer, and say whether their construction contemplates or permits the opportunities and advantages of repair or change which you have spoken of in your answer to interrogatory 3499 and subsequent questions.

A. They do not in any practical sense; that is, they cannot be readily taken down and set up again. I suppose, indeed I know, that a skillful glass-blower could take those lamps apart and a new carbon could be substituted or other change made in the interior of the lamp, and the lamp be again closed, refilled or exhausted, or both, and run again, but it would cost more than to make new glass parts for the lamp, preserving the metal parts.

X Q. 3505. Do you mean to say that it would be practical to do that with the lamp of the patent in suit, on the score of cost?

A. Yes, it could be readily taken down and a new carbon substituted, and the lamp be recharged or exhausted, and in many places to-day a lamp adapted for this purpose would be highly desirable. In referring to the lamp of the *the* patent in suit I simply refer to the type of lamp illustrated in the patent in suit, and do not mean to be understood that the invention sought to be covered by the patent in suit is limited to that type of lamp. If you refer to the cost of taking down a lamp and putting in new carbon conductors in lamps of the type of that illustrated in the patent in suit, the cost is entirely within the limits of practicability for many purposes for which incandescent lamps are or could be used to-day.

Adjourned till Wednesday, 3d inst., at 1 p. m.

1710 WEDNESDAY, *April 3d*, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant, and Mr. Lowrey for defendant, and the cross-examination of Mr. MAN proceeded as follows:

Mr. MAN here says: "I wish simply to say that in my answer to cross-question 3499, while I say that all the lamps made by Mr. Sawyer and myself were made so as to be readily taken down, &c., that my statement was intended by me as a general statement. The word 'all' is too broad, taken specifically, as a few lamps made by Mr. Sawyer, in which I did not participate, and one or two made by myself, were not intended to be taken down. If the word 'nearly' is put before the word 'all,' my answer would be correct."

X Q. 3506. Where are the one or two lamps which you have just spoken of as made by you; can you produce them, and will you?

A. I don't know. I at one time gave one of them to Mr. Broadnax, my counsel. They were made by Mr. Sharp and substantially illustrated by the drawing made by Mr. Sharp.

X Q. 3507. Do you now produce one of those lamps?

A. Yes, one of those made by Mr. Sharp, but not the one he illustrated.

X Q. 3508. Has this lamp which you now produce been in use?

A. Yes, I think so, only experimentally.

X Q. 3509. Please explain what was the arrangement of circuits and of incandescent conductors if there were to be more than one used in that lamp?

A. It was intended for two incandescent conductors.

1711 X Q. 3510. Where and for how long a time had you that is use?

A. At 43 Centre street while we were there. I should think in the month of March, 1878. The only use we made of it was simply a trial and not permanent use. The tubular conductors in the trial we made of it were covered at their ends with India-rubber tubing, and the tubing, after charging the interior of the lamp, was simply pinched together. The carbons were passed in through the tube and impinged upon the cross-piece hinged upon an upright held by a spiral spring in a central tube. The other lamp had lead tubing soldered to the ends of the tubular conductors after the carbon was put in, and had only one carbon, and after the lamp was charged the lead tubes were pinched together and melted to make them air tight. This lamp does not appear to have been run long enough to have determined any advantage in it, and so had not the means of permanently sealing it up attached.

X Q. 3511. There were two lamps similar in character, as I understand, one of which you produce, where is the other?

A. I don't know. It was at our shops. I don't know what became of it. It was never used after we left 43 Centre street.

X Q. 3512. Did you ever see it after leaving there?

A. No, sir.

X Q. 3513. You say the carbons were pushed up through the tubes in that lamp. Was it so in the lamp with the lead tubing?

A. Yes; there was only one carbon in the lamp, and the upper carbon piece was held rigidly instead of by a spring as in this case, and the carbon conductor was held up to it by a rod of carbon of the size of the bore of the tube, into which the end of a straight pencil carbon was inserted, and under the rod of carbon was a spiral spring to hold the carbon pencil up to the upper contact piece of the lamp. The holes through which the tubes pass are bored in the glass and sealed with binding screws. 1712

X Q. 3514. Did you insert the pencil or carbon before or after you had filled the lamp chamber with the atmosphere?

A. Before.

X Q. 3515. There are pieces here at the lower end of the tubular conductors which unscrew and come off. Were they removed for the insertion of the carbon and the filling of the lamp chamber?

A. They were removed for the insertion of the carbon, but were replaced and had lead tubes soldered to them before the charging of the lamp chamber. Not in this lamp, but in all glass lamps that Mr. Sharp illustrated.

X Q. 3516. What was the carbon material used in this lamp and the other?

A. Straight pencils of French carbon.

X Q. 3517. Do you mean of the Carre carbon?

A. Carre or some other French manufacture.

Said lamp put in evidence and marked "Defendant's Exhibit Experimental Lamp Produced by Man, April 3d, 1889."

X Q. 3518. How many types of lamps had you from the beginning of your work with Sawyer until its close in March, 1879?

A. I don't know that I could state. I have gone over that very fully, and it is only by going over from first to last all the work that we did that I could enumerate the different types. There were two general classes of the lamps, straight pencils and arched pencils, or V or other shaped, in which latter the incandescent conductor rose above or extended beyond both the holders or conductors leading to it.

X Q. 3519. I understand you to say that exhibit conductors put in evidence April 2d, 1889, are examples of part of the smaller forms of lamps?

1713 A. Yes, the shorter form of lamps. I think that they were used in the smallest form of lamps, but I can't be certain. I am sure they were used in the shorter form of lamps. They were conductors of this form that were used in the smallest form of lamps, perhaps of less size.

X Q. 3520. If I understand your recent testimony correctly, you made and set up between two and three hundred lamps of these various forms?

A. That is my estimate. I do not wish to be understood as swearing to positive numbers.

X Q. 3521. The lamps which you had were then made for your own use experimentally and otherwise?

A. It would be more accurate to say that they were not used, to my knowledge, except by ourselves and by Mr. Sawyer, after he separated from the Electro-Dynamic Light Co., unless they were used by some other people by direction of Mr. Sawyer in this later period. They were made, most of them, with a view of being sold.

X Q. 3522. Did you know in 1878 and 1879 of any rule by which you could have determined which was the better kind of fibrous material for your use without experiment?

A. One thing we took into consideration: The purity of the fibre to be carbonized. Our rule was to get as pure cellulose as possible, in which there was as little admixture of other things than gases and carbon (particularly metals or their bases), as possible. Another thing was to get a dense fibre, or one that was not too porous; another thing was to get a fibre that was uniform and that could be easily worked and put in shape before carbonizing. These rules, except the first, were learned by us very early by experiment. The first was determined when we determined to use carbon in our lamps. I do not know of any experience or rules of others at that time except the high resistance of pure carbon to heat, its high melting point, its infusibility.

X Q. 3523. By means of these experiments and the appli-
1714 cation of these rules, were you enabled within the range of

the materials which you examined to select the better and reject the worse natural fibres for your purpose?

A. We thought so, so far as our experiments extended, but it is proper to say our experiments and selection by means of them were limited to our then forms of lamps.

X Q. 3524. Did you make any experiments as to the kind of vegetable fibre most desirable, having in view standards of resistance in the incandesncing conductor, standards of size in main or distributing conductors, and other standard conditions of a business in which current is to be supplied from a central station for use in towns, cities, or villages? Did you assume conditions for this purpose?

A. We made experiments and calculations with reference to all things you mention.

X Q. 3525. Were there any of these conditions in respect to which you made these experiments and calculations in which you found willow carbon the best for the purpose?

A. I don't know or recollect.

X Q. 3526. Were there any of these conditions in respect to which you made these experiments in which you found carbonized paper the best for the purpose?

A. Confining myself to central station plant lighting, I do not know or recollect.

X Q. 3527. In your cross-examination you were asked (X Q. 964): "Now, if a person wanted to make a lamp under this patent with an incandescent conductor of fifty ohms resistance, what would he have to make the length or cross-section of his carbon?" and you answered: "I cannot tell without knowing the carbon that he was using and its resistance, and then only by experiment." Would not that be a correct answer in respect to any kind of carbon in any of the lamps which were made by you?

A. No, not in the sense that we could not or did not make carbons of any fixed or determined resistance which we desired.
1715 In the sense that I would have to know the elements I have mentioned there, of resistance in a particular case, before I could determine how to make the carbon, it is a correct answer. By "elements of resistance" in the conductor, I mean the specific resistance of the carbon to be used and its dimensions in either length or cross-section, which were not given to me in the question then asked.

X Q. 3528. Would the material of the carbon as to whether it was one vegetable or another vegetable fibre have anything to do with determining the question?

A. Yes, both the material and its treatment before carbonization.

X Q. 3529. Suppose in 1878 and 1879 you had wished to use incandescent lamps in multiple arc in the number of ten lamps of sixteen candles each for each horse power of current, and to attain the best duration of which you then had any experience, which one of the woods with which you were then familiar would you have selected as best for the purpose?

Obected to as not cross-examination and not material.

A. I speak from recollection that I think we should have selected willow, and treated the carbons.

X Q. 3530. Was that judgment the result of experiments which you tried on various kinds of wood?

Same objections.

A. It is a recollection only of what I think we would have done in looking back now upon the experiments we tried.

X Q. 3531. Are there any uses in electric lighting to which bamboo carbon would be applicable, and in which willow carbon would be either inapplicable, or less applicable?

Same objections.

A. I don't know; there may be, or may not.

X Q. 3532. Is willow carbon, to your knowledge, used anywhere at present in electric lighting?

1716 Same objections.

A. I have seen some lamps with willow carbon, a year or two ago. I don't know whether there is any use made of them now. I think it would be a good material to use now for some of the incandescent lamps.

X Q. 3533. Do you know whether there is any way of ascertaining if you are right in your last answer, except by experiment?

Same objections.

A. Yes; I know I could go to work and make good lamps of willow carbon, or, at least I think I could.

X Q. 3534. Do you mean that they would be commercial lamps in modern systems of lighting?

Same objections.

A. I mean that they would be good commercial lamps in some of the modern systems of electric lighting, in my opinion.

X Q. 3535. Have you any experimental experience, or are you answering according to your judgment merely?

Same objections.

A. I have not made any lamps since I quit working with Mr. Sawyer. I have advised in regard to the making of lamps at different times since then.

X Q. 3536. On page 48 of the minutes, on the eighth line from the bottom, I find the word "Sawyer's" between the word "his" and the word "judgment" interlined. Tell me if you know in whose handwriting is the interlineation.

A. In Mr. Sawyer's, I think.

X Q. 3537. Is the whole page in his handwriting?

A. Yes.

Adjourned till Thursday, the 4th inst., at 1 p. m.

1717 NEW YORK, *April* 4, 1889.

Met pursuant to adjournment.

Present: Counsel as before, and the cross-examination of Mr. MAN was continued as follows:

X Q. 3538. You have referred to Mr. Lowrey's visit to the shop of Sawyer & Man on the 30th of October, 1878, and have stated that you then exhibited to him your light. Please state whether you showed or communicated to Mr. Lowrey anything more than had been on the day previous communicated to the various representatives of the press?

A. I think that we exhibited to Mr. Lowrey about the same as was exhibited to the representatives of the press the day before, and in about the same manner. The lamps exhibited to him, according to my recollection, had straight-pencil incandescent conductors, and we told him that we made them of carbon. I do not recollect of anything being said of how our conductors were made or of any discussion of the carbon, except simply that we made them and they were of carbon; of course I cannot say at this length of time whether we told Mr. Lowrey some things that we did not tell the press representatives, or whether we told the press representatives some things that we did not tell Mr. Lowrey.

X Q. 3539. I hand to you what purports to be a letter signed by you and addressed to Charles A. Cheever, Esq., dated Dec. 12, 1880, and ask you to say whether that is your letter and whether it was sent to Mr. Cheever at or about its date?

A. Yes.

Said letter offered in evidence and marked "Defendant's Exhibit Man-Cheever Letter, April 4, 1889."

1718 Redirect examination:

R. D. Q. 3540. What, if any, profit have you made out of your enterprise in electric lighting entered into by you with Mr. Sawyer?

A. I have made none, and I have no prospect of making any, and on the contrary, have put in a great deal of money aside from my time, of which I see a prospect only of recovering a part.

R. D. Q. 3541. You have stated that Mr. Sawyer resigned the offices of secretary and trustee in the Electro-Dynamic Light Co. in the spring of 1879. State if you have refreshed your memory since as to the date of his resignation, and make such corrections as you wish to.

A. I think I stated when first examined in this case before Mr. Kitchen, examiner, that my impression was that Mr. Sawyer resigned in the spring or summer of 1879. I have not the means of referring to my testimony now, but that is the impression I have in regard to it. I have since refreshed my recollection by reference to the minute book of the Electro-Dynamic Light Co., which I had not then and had not for years before been able to examine. I find by the minutes of the meeting of the trustees of the Electro-Dynamic Light Co., in my own handwriting of Nov. 20, 1879, that Mr. Sawyer's resignation was accepted at the meeting of that day. I find by the minutes of the meeting of October 7th, 1879, at which Mr. Sawyer was also present and at which meeting no business was transacted except to adjourn, that I acted as secretary, although Mr. Sawyer was present. My recollection therefore is that Mr. Sawyer offered his resignation in the fall of 1879, and before or on October 7th.

R. D. Q. 3542. State whether or not you have recently furnished the Consolidated Electric Light Co., or the Sawyer-Man Electric
Company, its licensee, with parts of Sawyer-Man lamps, to
1719 be used by them in the construction of such lamps, to be
used as exhibits in this case, and if yea, please to state what
parts you furnished?

A. During the year last past I have furnished to them the parts of the Sawyer-Man lamps, enough for about from thirty to fifty lamps, made or caused to be made by Mr. Sawyer and myself (while we were working together) for the Electro-Dynamic Light Co. in 1878 and 1879, and which I have had in my possession ever since then. I delivered these to Mr. Robertson, Mr. Packard and Mr. Garden. The parts I think were complete for nearly all the lamps, except the carbon-holders, possibly some diaphragms and the carbon incandescing conductors. They were glass globes, glass base plates, binding rings, tubular binding screws, with stop-cocks, cups to cover the stop-cocks and binding screws, corrugated leading-in conductors, spun caps for covering the base of the lamps made of sheet metal. I have also given to Mr. Packard, Mr. Shallenberger and others instructions as to the making and purification of nitrogen gas and the details of work in setting up and sealing the lamps, and part of the material I furnished was sent to Mr. Shallenberger at Pittsburgh.

R. D. Q. 3543. Please to give the name of the person who put up for you at your Walker-street shop the water-exhausting apparatus referred to by you in your answer to question 3453.

A. David Hennessy.

R. D. Q. 3544. In the article taken from the New York Times of October 30, 1878, and put in evidence by defendant's counsel, it is stated:

"The pencil of carbon is heated by the electric current with a temperature of from 30,000 to 50,000 degrees Fahrenheit, in an atmosphere with which it cannot chemically combine."

State if you know what authority there is for that statement.

1720 A. Mr. Sawyer and I made experiments to ascertain what degree of heat carbon would endure without softening or becoming flexible. Our experiment was made in this way; we took different metals whose melting points were known, placed them in our lamps, passed through them currents of definite quantity and electro-motive force to heat them up to the melting point, turning in the electric current gradully. We took carbon conductors and turned into them currents of the same electro-motive force and quantity, or amperes, as those at which the different metals melted. We took into consideration the resistance of both the metals and the carbon conductors and their specific heats. From this we ascertained, or thought we did, in a rude way, approximately, the temperature of the carbon conductors at different degrees of luminosity. From this we deduced a rule of temperature of the carbon conductors as their luminosity increased. It was a rough and crude way of approaching the subject, but from it we came to the conclusion that pure carbon would soften and bend at a temperature of 30,000 to 50,000 degrees. Mr. Sawyer was in the habit of stating that we had found out that these carbons that we used would stand from 30,000 to 50,000 degrees Fahrenheit. I never heard him make the statement that we ran our lamps at such a temperature, and I think I certainly never made such a statement. I know of no other authority for its being stated in the newspapers than that I have given. I think the reporter must have got the idea from some statement of what degree of heat we thought carbon conductors would endure.

ALBON MAN.

Counsel for complainant offers in evidence a diagram made by the defendant's witness, Wm. Sharp, of the Walker-street shop, in answer to question 547 of his deposition and the same to be taken as part of his said deposition, the same is marked "Complainant's Exhibit Sharp's Diagram of Walker-street Shop, April 4, 1889."

Adjourned till Friday, April 5th, 1889, at 1 p. m.

1721 COMPLAINANT'S EXHIBIT CHEEVER AGREEMENT, W. T. F., S. E.

Agreement made by and between the Electro-Dynamic Light Company, organized under the laws of the State of New York, and having its principal place of business in New York city, party hereto of the first part, and Charles A. Cheever, of the city, county and State of New York, party hereto of the second part:

Witnesseth, that whereas, the party of the first part is the owner of a certain improvement in electric lights or lamps, consisting in the use of an incandescing arc of carbon, the joint invention of William E. Sawyer and Albon Man.

And whereas, the party of the second part is desirous of acquiring the ownership and control of said invention for the United States and of any letters patent of the United States granted therefor; to which end he desires time in which to negotiate with other parties in relation to the purchase of said invention and patent for the common benefit of the parties hereto:

Now, therefore, in consideration of the premises and of other good and valuable considerations, them thereunto moving, it is agreed and covenanted between the parties hereto as follows:

1. The party of the second part shall have the right or option of purchasing said invention, as described and claimed in that application, this day prepared and executed, and shown in the models and drawings thereof, and in any letters patent which may hereafter be granted in the United States therefor, thereon for the sum of one hundred thousand dollars in cash, during the coming week,

ending at midnight of Saturday, January seventeenth, eighteen hundred and eighty.

1722 2. The expense of preparing and soliciting the patent herein referred to, is to be borne by the party of the second part, as far as incurred during the existence of this option. In case he fails to purchase, he is to be liable for no further expense, but in case of a consummation of the purchase, all further expenses, costs and charges are to be borne by the party of the second part.

3. It is understood between the parties hereto that said party of the second part will complete his negotiation at the earliest practicable moment; but in case delays should occur, if matters are in such condition that further time can be given to complete such negotiations, without loss to the party of the first part, or complications of its affairs, such time may be given by mutual consent.

CHAS. A. CHEEVER.

Dated January 9th, 1880.

Witness to C. A. C.:
W. K. APPLEBAUGH.
WILLIAM D. BALDWIN.

1723 COMPLAINANT'S EXHIBIT LOWREY LETTER OF OCTOBER 30, 1878. March 28, 1889. W. T. F. E. E.

John K. Porter, Grosvenor P. Lowrey, Geo. Wales Soren, Ch. Francis Stone, George S. Hamlin.

Porter, Lowrey, Soren & Stone, attorneys and counsellors at law, No. 3 Broad street, Drexel building.
P. O. box 1836.

NEW YORK, *October 30th*, 1878.

DEAR SIR: Referring to my visit to 94 Walker street this morning, I think it desirable to repeat to you more deliberately than may be done in a hurried conversation that the field of electric lighting is so vast, and promises such great results that good business men would commit a great error if they should allow themselves to become, in the outset, involved in any uncalled-for struggle for the possession of the whole field, and a small part of it would be enough for all.

As I said to you this morning, the suggestions which passed between us, arising apparently in both our minds out of the same practical considerations, were not intended by me to express the opinion of my associates, for I had not seen any of them since reading in the morning paper the announcement of the Sawyer-Man light; nor do I understand what you said as in any way committing you, except to the general proposition that it was always in these matters wiser to unite strong parties than to divide them, and leave them to expend themselves in opposition.

I want to repeat, therefore, that I shall be at all times in favor of considering more carefully the general ideas which we mutually expressed, and that without any very great reference to the question, who would or who would not succeed in the final contest.

1724 As I understand it, you have not a correct idea of Mr. Edison's light; in fact, he has not allowed any one to know what his intention consists of, but I understand that you have what is apparently to me a very good light, and even if we were able to sustain both rival patents we should be competitors in business, which itself would be commercially a great mistake.

I have already described to one of the directors of our company what I saw of your light and I shall mention our conversation to others as I shall chance to meet them.

You will be glad to hear that a telegram from Menlo Park this morning informed me that Mr. Edison slept twelve hours last night without pain, and is therefore out of the difficulty which has prevented him *for* working for the last few days.

I presume that your foreign patents are taken out, and I think there is a much greater field over there than here, and also if there should be a practical union of these interests in any way, it would be enormously to the advantage of both, on the other side, to be represented by the same strong banking house or houses.

Very truly yours,

(S'd) G. P. LOWREY.

Albon Man, Esq., 94 Walker street, city.

1725 COMPLAINANT'S EXHIBIT MAN'S LETTER TO LOWREY OF OCTOBER 31, 1878. March 29, 1889. W. T. F., S. E.

NEW YORK, *October* 31, 1878.

DEAR SIR: I have to acknowledge the receipt this afternoon of your letter to me of Oct. 30th inst. We feel very confident of the success of our inventions and the stability of our patents. Some of your people, and if we are not mistaken, from Mr. Edison's own laboratory, have seen our light and can attest its excellence, as can also a vast number of people who have thronged to see it. Of course we have not made public all that we have done, nor do we suppose that Mr. Edison has done so, but we do distinctly claim that we are the inventors of all that we use, and that we can show our priority over Mr. Edison and every one else in these inventions, and we cannot but feel from what we see published that many of these inventions are essential to the successful working of Mr. Edison's light.

If we are right, Mr. Edison's light, if put in operation, must in the end pay tribute to us. At the same time, my dear sir, we do not claim to be all the world, nor to contain all the wisdom of it, nor to know in advance all that has been and will be found out about lighting by electricity. Permit me just here to pay what is but just tribute to the ability, skill and inventive talent of Mr. Edison, and to admit that his well-known character in this respect is a great advantage to those attempting to bring his inventions before a public whose confidence in him as an inventor is great. I admit at the same time the high character, standing and wealth of your associates, as you must that of those who are associated with us.

1726 I do not permit myself for a moment to think that either you, or those associated with you, would think of attempting to deprive us by litigation or otherwise of our just rights, notwithstanding any inference to the contrary that might be drawn from your letter. Having thus cleared the ground, I have to say that I can see no ground of objection to a union of interests that should do away with antagonism, if a fair basis for such union can be found. But on the contrary I can see, and I have no doubt the eminent business men who are associated with us in interest would also see, that great advantages might be derived to both companies from such a union.

If you will bring about the appointment of a proper committee from your company for the purpose, I will see to it that representatives from our company shall meet them as soon as you advise me, for the discussion of the subject. The matter may be informal if you desire it, at first.

I am happy to hear of Mr. Edison's improved health.

In the matter of foreign patents I believe we are all right.

Very respectfully yours, ALBON MAN.

G. P. Lowrey, Esq., Drexel building, cor. Wall and Broad streets, N. Y.

1727 COMPLAINANT'S EXHIBIT LOWREY LETTER OF NOVEMBER 6, 1878. March 29, 1889. W. T. F., S. E.

John K. Porter, Grosvenor P. Lowrey, Geo. Wales Soren, Ch. Francis Stone, George S. Hamlin.

Porter, Lowrey, Soren & Stone, attorneys and counsellors at law, No. 3 Broad street, Drexel building.

P. O. box 1836.

NEW YORK, *Nov. 6th*, 1878.

DEAR SIR: I received your letter of Oct. 31 inst. as I was leaving my office. I had time to glance at the first page of it hastily, and then, thinking I might not have another opportunity for several days, I dictated to my stenographer my letter to you of November 2d and left it to be written out and signed by him for me. I have just this morning returned to the city and take the first opportunity to make a more formal reply.

I adhere to the general ideas of policy which I expressed to you in conversation and in my former letter. I do not think the matter is in any situation, however, to require the present consideration of whether or not we are likely to be rivals, and as such, injurious to each other. That time may very likely come, and perhaps soon, and of one of those interested in Mr. Edison's patents, I shall be ready and disposed towards whatever may seem to be required by good business judgment.

1728 I should not allude to any possible contest between our patents, except from your having exppessed a belief (very proper from your standpoint) that "Mr. Edison's light, if put in operation, must in the end pay tribute" to you.

I am entirely satisfied that the most exhaustive search of what has been done others will show that Mr. Edison has produced a perfectly novel invention.

Very truly yours, G. P. LOWREY.

Albon Man, Esq., 3 Mercer St., city.

1729 Complainant's Exhibit Sawyer's Letter, Dated March 7, 1878. March 27, 1889. W. T. F., S. E.

Office of the United States Electric Engine Co. (74 & 75 Coal and Iron Exchange), 21 Cortlandt St.

New York, *Mar.* 7, 1878.

Dear Sir: I received your note too late to see you yesterday, having been very busy running round all day. Before receiving it I had made an important appointment for this morning, and could not therefore come round to-day.

There is no machine at Columbia college, but I have got hold of a Hochausen machine that answers the purpose. Shall have it all this week, but not next week. I have hired a room, this morning, at 43 Centre street, up one flight, and the wires are now being run. Expect to do something this afternoon. If you can come round between 2 and 4, I will meet you there. Ask the engineer in the basement for my location. The entrance is by an arched way from Centre street.

The difficulty seems to be vanquished, although the machine is not just what we want.

I tried the full power on a lamp yesterday, and you would have supposed a small sun was shining in the vicinity.

Truly yours, in haste, W. E. SAWYER.

1730 Complainant's Exhibit Lowrey Letter of Nov. 2, 1878. March 29, 1889. W. T. F., S. E.

New York, *Nov. 2d*, 1878.

Dear Sir: I have this moment received your letter, which, however, I have not time to read, as I am going out.

I was surprised this morning to hear that my letter to you was spoken of as an advance towards a consolidation of our company with yours. I am sure you cannot have made such a mistake. At any rate, if such an impression was derived from what I wrote, there was no such specific purpose in my mind, and I desire to correct it now and to add that I have not the slightest idea that the Edison Electric Light Co. would entertain any such proposition from you, and certainly they would not make it.

It is one of the dangers of private intercourse that it is liable to these misconstructions.

Very truly, G. P. LOWREY,
By K.

Albon Man, Esq., 94 Walker St.

1731 (Vol. II.)

United States Circuit Court, Western District of Pennsylvania.

No. 5, May Term, 1888.

In equity.

THE CONSOLIDATED ELECTRIC LIGHT COMPANY
vs.
MCKEESPORT LIGHT COMPANY.

Testimony on Part of Complainant in Reply, Taken before William T. Farnham, Special Examiner, under Order of Court Reopening the Testimony.

NEW YORK, *March 30th*, 1889.

Present: Thomas B. Kerr, counsel for complainant; and Richard N. Dyer and *and* Walter K. Griffin, of counsel for defendant.

1732 THOMAS B. STILLMAN, a witness on the part of the complainant, being duly sworn, deposes as follows in answer to interrogatories by Mr. KERR:

Int. 1. Please to state your name, age, residence and occupation.

Ans. Thomas B. Stillman; age, 37; residence, Hoboken, New Jersey; my profession, analytical chemist.

Int. 2. Were you acquainted with William E. Sawyer; and if so, when did you get to know him?

Ans. Yes, sir; in December, 1878.

Int. 3. Are you acquainted with Albon Man? If so, when did you get to know him?

Ans. Yes, sir; at the time that I became acquainted with Mr. Sawyer.

Int. 4. Under what circumstances did you become acquainted with Sawyer and Man?

Ans. I was consulted by them at that time in regard to the preparation of pure nitrogen gas

Int. 5. For what purpose?

Ans. The gas to be used in the filling of the Sawyer and Man electric lamps.

Int. 6. Did you do any work for them at that time; and if so, what?

Ans. I did. I arranged an apparatus for manufacturing and purifying nitrogen gas, and also filling the lamps with the same.

Int. 7. Where did you arrange this apparatus?

Ans. In the first place at 94 Walker street at their factory; and in the second place at my laboratory at 40 Broadway.

Int. 8. Did they have any apparatus for that purpose at 94 Walker street before you arranged the apparatus you have spoken of for them?

Ans. They did.

Int. 9. Please describe it.

Ans. It consisted of a large glass retort connected to a series of Wolff *pottles*. The Wolff bottles contained purifying agents, and a large rubber bag as a receiver.

1734 Int. 10. Will you please produce drawings of the apparatus for purifying nitrogen gas and for filling the lamps, which was arranged by you for them?

Ans. I now produce the drawings required, which I have marked "Stillman No. 1" and "Stillman No. 2;" drawing No. 1 representing the method of preparation of the gas, and drawing No. 2 the method of purification of the gas.

The drawings produced by the witness are offered in evidence as Complainant's Exhibits Stillman No. 1 and Stillman No. 2, W. T. F., examiner, March 30, 1889.

Int. 11. Please describe the apparatus shown in the drawing "Stillman No. 1."

(Here follows diagram marked p. 1733.)

Ans. It consists essentially of a retort marked "A," in which is placed a mixture of chloride of ammonium and nitrate of potassium, which, upon the application of heat and a sufficient quantity of water, generate nitrogen gas. This gas is then passed through a Wolff bottle marked "B," containing some oil of vitriol as a dryer, then through the Wolff bottle marked "C," containing a solution of sulphate of iron, then through the Wolff bottle marked "D," containing a solution of pyrogallate of sodium; then through the Wolff bottle marked "E," containing sulphuric acid; then through the Wolff bottle "F," containing raw cotton; thence to the receiving gas bag marked "G."

Int. 12. Please describe the apparatus shown in the drawing Stillman No. 2.

(Here follows diagram marked p. 1736.)

Ans. The gas bag full of the gas is put in connection with the following system of purifiers; first through Wolff bottle "H," containing solution of sulphate of iron; thence through a Wolff bottle marked "I," containing solution of pyrogallic of sodium; thence through the Wolff bottle marked "J," containing oil of vitriol into a series of long glass tubes marked 1 to 7 respectively, and shown in the drawing as "K." Tube No. 1 contains oil of vitriol;
1735 tube No. 2, broken pieces of caustic potash; tube No. 3, solution
of sulphate of iron; tube No. 4, sticks of caustic potash; tube No. 5, solution of sulphate of iron; tube No. 6, oil of vitriol; tube No. 7, containing phosphoric anhydride; thence into a wash bottle containing cotton; thence into an iron tube containing metallic sodium, the metallic sodium being kept melted by means of a Bunsen combustion burner, through which the tube passes; this tube is marked No. 8 in the drawing. From thence the gas passes

through two bulbs containing phosphoric anhydride; thence into a Wolff bottle filled with cotton, and thence to the lamps.

Int. 13. Did you make any use of this apparatus at 94 Walker street?

Ans. I did. For preparing nitrogen gas to be used in the Sawyer-Man electric lamps, and I filled the lamps by the process and the apparatus just described.

Ans. 14. Please describe those lamps which were filled by you?

Ans. These lamps were the lamps being made by the Sawyer-Man people at 94 Walker street. They were all incandescent electric lamps, the light being given by a small piece of incandescent carbon in each instance. The carbons used were of various forms and material. There was the straight willow carbon, treated and untreated. There was the straight Carré carbon. There was the horseshoe paper carbon, treated and untreated; also the willow carbon, hollow and treated. Various names were given in the shop to these different forms of carbon, for instance, we had the straight-pencil carbon which was called the hammer and anvil. There was the plain arch, and the straight willow. Those were the three principal ones made at the time I was at the factory. The lamp consisted essentially — two metallic electrodes of various forms; but usually of two pieces of brass conductors passing through the base of the lamp, one to about three-quarters of the distance up, the other paralle*l* to it, and extending*s* some distance further up the globe. The ends of the brass rods or tubes were connected to large pieces of carbon which 1737 acted as the receiver for the pencils of carbon used as an illuminant. Various devices were made use of to maintain the contact of these larger pieces of carbon perfect with the carbon used as the illuminant. In the straight-pencil lamp a long and delicate spring extending from the upper portion of the brass conductor connected with the upper end of the pencil, extended to the base of the lamp, retaining the pressure of the carbon uniform when in a heated cond*d*ition. In the arch lamp, however, no use was made of the spring for this purpose, as it was found by experiment that the passage of the current through the carbon arch did not rupture the carbon and that the arch itself relieved the carbon of the strain. In filling the lamps with nitrogen gas, the gas was passed through a tube to the upper end of the globe and the air displaced by the nitrogen passing out through an aperture at the base in the other side. When the air had been displaced a current of electricity was turned onto the lamp and the carbon maintained in a state of incandescence from one-half hour to an hour to drive out any occluded gases that might be present. The filling tube was then withdrawn, valves turned, and the lamps closed. Lamps standing this test were passed by me and sent to the factory or office for exhibition. The base of the lamp consisted of two glass plates attached to the end of the globe by means of screws running up through the plates. The plates were joined together by means of Canada balsam, when the lamps were filled, sealing wax was then placed around the base, securing the interior of the globe from admixture with the air from the outside. A short time after my working in the factory at 94 Walker street, I ordered a sealing mixture for the base of the lamp, as the wax at times became soft. To overcome this a mixture containing caoutchouc was used, which when cold adhered firmly to the glass and made a tight joint. The globe of the lamp was a long cylindrical one about two inches in diameter, and from six to ten inches in length.

Int. 15. About how many lamps did you fill at 94 Walker street?

1738 Ans. Forty or fifty lamps.

Int. 16. Can you tell what proportion of these had arch-shaped paper carbons?

Ans. I should judge about a third.

Int. 17. You spoke about putting up a purifying and filling apparatus at your laboratory No. 40 Broadway. Please state when you did this and why.

Ans. The latter part of December, '78 or first of January, '79, I transferred the apparatus from the Walker-street shop to my laboratory at 40 Broadway, as I could not devote all my time at the factory.

Int. 18. Did you fill any lamps at No. 40 Broadway for Sawyer and Man?

Ans. I did.

Int. 19. About how many?

Ans. There were a good many lamps. I couldn't tell you how many; over a hundred to a hundred and fifty.

Int. 20. What was the character of the carbons in these lamps?

Ans. The same as I have previously described—straight-pencil carbons and arch carbons.

Int. 21. What was the material of the arch carbon?

Ans. Paper carbon.

Int. 22. About what proportion of the lamps which you filled at 40 Broadway were provided with arch-shaped paper carbons?

Ans. I think the proportion was smaller than that at the Walker-street shop, probably a quarter instead of a third.

Int. 23. Was there any test applied to the lamps you filled at 40 Broadway?

Ans. Each lamp was subjected to the current of electricity and the carbon kept incandescent from one-half hour to an hour. No further test was made at my laboratory, but if the lamps maintained this incandescence without break or change in the carbon the lamps were returned to the factory as properly charged.

1739 Adjourned until 2 p. m.

Met pursuant to adjournment.

Int. 24. Have you any record of any tests made with those lamps at 40 Broadway, and if so, please produce it and explain it.

Ans. I have, and now produce a record of some lamps tested January, 1879. This record shows the test made of some lamps sent to my laboratory from the Walker-street factory to be charged with nitrogen gas. The first date is January 6th, 1879, on which

Date	Number of Lamps filled	Kind of Lamps	Remarks
Jan'y 6th	3	1 H.A. plain 1 H.A. S.P. 1 arc.	H.A ~~plain~~ S.P. poor contact (II) H.A. plain ~~good~~ fair carbon but the anvil & hammer carbons appear short and poor. The arc in fair condition but contacts not very secure. The arc gives a light of about 4 candles with 10 Lalande cells. If properly secured it will doubtless be the most economical and rational form yet devised -
Jan 8th	1	large willow carbon.	
" 9th	3		No 1, anvil, No 2 crescent, both good. No 3 burned 8 minutes.

Cons E L Co
v.
McKeesport Co

date three lamps were sent down to be filled by me, one being a hammer-and-anvil plain carbon, one hammer-and-anvil specially prepared or treated, and one arch lamp, the latter being a paper carbon. The entry of January 6th contains the following remarks:

"The hammer-and-anvil specially prepared—poor contact. The hammer-and-anvil plain—good fair carbon, but the hammer-and-anvil carbons appear short and poor. The arch in fair condition, but not very secure. It gives a light of about four candles with ten Ladd cells. If contacts are properly secured it will doubtless be the most economical and rational form yet devised."

This entry was made in the handwriting of my partner, Mr. William H. Fuller. January 8th is a record of one lamp marked "large willow carbon" with no remarks. January 9th three lamps were sent down, as follows: No. 1, anvil; No. 2, Crescent; No. 3, straight carbon. Under the head of remarks, No. 1, anvil, and No. 2, Crescent, both good. That is to say, they stood the test required by me, and were returned to the shop as satisfactory. No. 3, straight carbon, burned eight minutes. On January 10th one lamp was sent down marked "willow carbon, large." The remarks under this show that it burned eight minutes. On January 12th three lamps were sent down for me to fill, No. 1 being an arch lamp, No. 2 hammer-and-anvil, and No. 3 willow carbon. Under head of remarks, "arch lamp formed arc in current of battery."
1741 No. 2, treated-wood carbon, hammer-and-anvil, stood the test fifteen minutes; marked "good fifteen minutes." No. 3, willow carbon, "not good, four minutes." On the 13th of January four lamps were sent up. On the 14th, three lamps. On the 16th, four lamps. Under remarks it states "Of the lamps (7) sent up January 12th and 13th four burned good."

Paper offered in evidence as Complainant's Exhibit Stillman Record of Lamp Tests, W. T. F., examiner, March 30th, 1889.

(Here follows lithograph marked p. 1745.)

Int. 25. You state that the entry of January 6th, 1879, on this exhibit, is in the handwriting of your partner Mr. Fuller. Is he still your partner?

Ans. He is not. We dissolved partnership in 1880.

Int. 26. Do you know where he is now?

Ans. No; I do not.

Int. 27. In whose handwriting are the other entries on this exhibit?

Ans. In my own handwriting.

Int. 28. When were they made?

Ans. At the dates set forth on the exhibit.

Int. 29. Where has that exhibit been since 1879?

Ans. In my desk at my office, 40 Broadway.

Int. 30. Does this record show all the lamps which were filled and tested by you at 40 Broadway?

Ans. No, sir.

Int. 31. Have you any other record showing the tests of the other lamps?

Ans. Not that I know of. I have looked but could not succeed in finding any.

Int. 32. Was it your custom to keep a record of all the tests you made of those lamps?

Ans. It was not.

Int. 33. How did this record happen to be made?

Ans. It was started by Mr. Fuller, and I carried it along for a few days, later the lamps came more at a time and I had not the time to devote to it, and another reason was that no check record was kept at the factory of the lamps that I checked off at the laboratory.

1742 Int. 34. Did you ever see any of these arch-shaped paper-carbon lamps in use at 94 Walker street?

Ans. Yes, sir.

Int. 35. Please state how they burned.

Ans. Some burned well and some poorly.

Int. 36. Do you know what was the cause of the difference in the operation of those lamps?

Ans. My impression is that it was a mere mechanical difficulty, a failure to make proper contact between the carbon. Some lamps sent down to be filled, plainly showed this, as the record in the last exhibit also shows.

Adjourned until Monday, April 1st, 1889, at 11 a. m.

NEW YORK, *April 1st*—11 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

Int. 37. What does the part marked " L " in the drawing Stillman No. 2, indicate?

Ans. It indicates the rack for holding the lamps during filling, the lamps being indicated in position by the letter " M."

Int. 38. Was there any other apparatus used in filling the lamps which is not shown in the drawing Stillman No. 2?

Ans. There was. It consisted of dryers and a large aspirator, the dryers being used to prevent any contamination of moisture, and so forth, from the air, which might possibly come from this end of the apparatus, and a stop-cock to shut off the apparatus when completed.

Int. 39. Will you please make a drawing illustrating this additional apparatus and produce it at the meeting to-morrow morning?

Ans. I will.

Int. 40. Please state whether you made any exhaustion of the lamp globes.

1743 Ans. Yes, sir, I did.

Int. 41. Please describe the apparatus you used for that purpose.

TRANSCRIPT OF RECORD.

SUPREME COURT OF THE UNITED STATES.

OCTOBER TERM, 1893.

No. ~~286~~. 44

THE CONSOLIDATED ELECTRIC LIGHT COMPANY,
APPELLANT,

vs.

THE McKEESPORT LIGHT COMPANY.

APPEAL FROM THE CIRCUIT COURT OF THE UNITED STATES FOR THE WESTERN DISTRICT OF PENNSYLVANIA.

FILED OCTOBER 17, 1890.

(14,326.)

Ans. It was a simple water exhaust at use at 94 Walker street. A large number of the lamps were exhausted there and sent to me in an exhausted condition at 40 Broadway. I also exhausted some in my laboratory at the suggestion of Mr. Man, before charging the lamps with nitrogen. In my laboratory I made use of the mercury vacuum. In a few of the lamps the air was displaced by coal gas, and the coal gas displaced by nitrogen, and then the lamps sealed. The mercury vacuum consisted of a glass globe, two openings at the top, with stop-cocks, the lower portion of the globe being drawn down to a tube, in which tube was also a stop-cock. This globe was connected by rubber tubing to a large bottle, similar in shape to a Wolff bottle, but having a stop-cock at its base. The method of using it was as follows: Mercury was placed in the glass bottle, the stop-cocks in the glass globe opened and the bottle containing the mercury placed upon a shelf some two or three feet above the height*h* of the glass globe. When the mercury had filled the glass globe up to the stop-cocks they were closed, the stop-cock connecting with the apparatus was opened, the glass bottle removed from the shelf to the floor, the stop-cock at the base of the glass globe opened, allowing the mercury to descend from the glass globe to the bottle, thereby filling the glass globe full of air which was formerly in the apparatus—in the lamps to be charged. This operation was repeated until we were satisfied that the air had been taken out of the lamps.

Int. 42. You have spoken of the conductors in the lamps as being of unequal length. Was that the case with all the lamps?

Ans. No, sir. I referred to the hammer-and-anvil lamps—straight carbon. In the arch lamp of paper carbon they were of the same height.

Int. 43. You have given the size of lamps filled by you, were they all of the same size?

1744 Ans. No, sir, they varied in length and breadth.

Int. 44. In the first entry on Complainant's Exhibit Stillman Record of Lamp Tests, namely, that of January 6th, in the handwriting of Mr. Fuller, one of the lamps is referred to as an arc lamp. Was that what is commonly known as an arc lamp?

Ans. It is not. It refers to an incandescent arch lamp.

Int. 45. Referring now to the filling tubes, did all these lamps have a *long* filling tube reaching to the top?

Ans. Some of the lamps required a tube to be placed in during the process of filling, while in others the metallic conductor reaching to the top of the lamps was hollow, and served the purpose of a filling tube.

Int. 46. Have you any recollection of the life of any of the Sawyer-Man lamps filled by you?

Ans. I have. Several of the lamps burned finely for a number of days, while one in particular burned several weeks in the shop at Walker street, and was in good condition when broken accidentally by one of the workmen in hammering something on the wall.

Int. 47. Where was this lamp placed when in use?

A. Part of the time in the shop and part of the time in the office at 94 Walker street.

Int. 48. In what part of the shop?

A. Over the workmen's bench.

Int. 49. Please state what kind of a carbon that lamp had.

A. It was a straight treated carbon, and when the lamp was broken the carbon appeared of a silvery white color without any apparent break to it.

Int. 50. What was the atmosphere in that lamp?

A. Nitrogen gas.

Int. 51. What was its mechanical construction?

A. The construction was the same as the hammer-and-anvil lamps I have already described.

Adjourned to meet on Tuesday, April 2d, at 10 a. m.

1746 New York, *April 2d*, 1889—10 a. m.

Met pursuant to adjournment. Present counsel as before.

The examination of Mr. Thomas B. Stillman was resumed:

Int. 52. To what in your opinion was the durability of this particular lamp due?

(Objected to as incompetent.)

A. To proper contact between the carbons, and proper filling with nitrogen gas.

Int. 53. Do you remember anything about the subsequent history of that lamp?

A. Yes, sir. The same lamp was set up with the same carbon and filled with nitrogen gas and run for a few hours when an arc formed in the carbon, caused by poor contact, and the carbon was soon destroyed.

Int. 54. You speak in question 46 of several of the lamps burning finely for a number of days. What kind of carbons did these lamps have?

A. They were of all the various forms of carbon sent down to the laboratory to be filled—straight pencil, arch paper carbon.

Int. 55. How did you come to know about the lives of these lamps?

A. By being in the shop off and on from day to day, meeting people there who were interested in the lights, and who were carefully watching them and who were very much interested in the existence of the lamps.

Int. 56. Was it any part of your business to take records of the lives of the lamps?

Ans. No, sir.

Int. 57. Can you produce any letters from William E. Sawyer in regard to the filling of lamps, and if so, please produce the same.

Ans. Yes, sir. I produce a letter written to me by Mr. Sawyer March 5th, 1879, regarding the filling of some lamps by me with nitrogen gas.

12. Aspirator.

1747 (The letter is offered in evidence as Complainant's Exhibit Sawyer-Stillman Letter of March 5, 1879, W. T. F., examiner.)

Int. 58. I notice that the year is not given on that letter. What makes you say it was written in 1879?

Ans. I identify it by means of the composition of the letter, and from the fact that at that time the base of some of the lamps was sealed up with sealing wax.

Int. 59. Where has that letter been ever since it was received by you?

Ans. In my office desk at 40 Broadway.

Int. 60. Are you familiar with the handwriting of William E. Sawyer?

Ans. Yes, sir.

Int. 61. Is this letter in William E. Sawyer's handwriting?

A. Yes, sir; it is.

Int. 62. In question 39, during yesterday's examination, I asked you to produce a drawing showing the additional apparatus used in filling the lamps. Have you made *made* and will you now produce such drawing?

Ans. I have, and now produce it.

(The drawing is offered in evidence as Complainant's Exhibit Stillman No. 3, W. T. F., examiner.)

(Here follows diagram marked p. 1740.)

Int. 63. Please describe the apparatus shown by the drawing and its operation.

Ans. The last lamp in the series marked "M" is connected with a straight glass tube containing the stop-cock "N." This tube is connected with another passing through a wash-bottle containing sulphuric acid marked "10" in the drawing, then through another wash-bottle containing sulphuric acid marked "11." This is connected with a large aspirator in which there is a safety glass tube passing through the liquid and out through the top of the aspirator. This safety tube indicating by the rise and fall of water in the tube the pressure of the gas passing. The fall of the water from the aspirator is regulated by a stop-cock, marked "13." When 1748 the air is displaced out of the lamps by the nitrogen, the gas is shut off from the bag "G" and the water allowed to run from the aspirator 12 until the safety valve in the aspirator shows a slight exhaust existing through the system. The stop-cock marked "N" is now turned off and the lamps sealed in the usual manner. The gas is shut off from the bag G by the stop cock shown in the figure at the neck of the bag.

Int. 64. What was the object of the slight exhaust you have spoken about in your last answer?

Ans. The object was to have the amount of gas in the globes that when the lamps were burning the gas being expanded by the heat generated by the incandescent carbon would be under normal atmospheric pressure.

Cross-examination by Walter K. Griffin, Esq., counsel for defendant:

X Int. 65. Up to what time did you continue to fill lamps for Mr. Sawyer?

Ans. Until the company moved to Ansonia, Connecticut.

X Int. 68. What was the date of this?

Ans. I think in the spring of 1879.

X Int. 67. Have you any books or papers which enable you to fix the date?

Ans. No papers relating directly to the moving of the company to Ansonia, but I have one or two letters from Mr. Sawyer written from Ansonia to me in the summer of 1879 in regard to the use of bisulphide of carbon in prisms. He was then with Wallace & Co., of Ansonia, Conn.

X Int. 68. Were you acquainted with the lamp called by Mr. Sawyer the feeder lamp?

(Objected to as incompetent and irrelevant.)

Ans. I was.

X Int. 69. Did you fill any of these feeder lamps for Mr. Sawyer?

1749 Ans. My impression is I filled a few. These lamps were much larger than the Sawyer-Man lamp and were made at his factory on Fulton street, over McKeson & Robbin's drug store, city, Mr. Sawyer then acting for the Eastern Electric Manufacturing Co.

X Int. 70. Have you any books or papers showing your charges for services rendered Messrs. Sawyer & Man during the period you have mentioned?

Ans. No, sir.

X Int. 71. Did you ever have any?

Ans. In my partnership with Mr. Fuller at that time an account was kept of disbursements and receipts of matter belonging to firm work but not of individual work, that is to say, our partnership was of such a nature that all work brought into the office from parties unknown to us was considered firm work; but through our friends, individual work. In this way I considered that the work brought to me by the Sawyer-Man people, through Mr. Edwin L. Myers, who was a former student of mine, belonged to me exclusively. I have no record, so far as I know, of the amounts paid me by Sawyer and Man, nor at the present moment have I any idea what it was.

X Int. 72. Will you please look and see if you can find any such record?

Ans. I will; but I can state in a general way that payments were made by check, and I think those amounts could be obtained from the treasurer of the company.

X Int. 73. When were you last at the shop, 94 Walker street?

Ans. In the spring of 1879.

X Int. 74. How late in the spring?

Ans. My impression is that it was about April.

X Int. 75. Do you remember seeing at any time at Walker street certain feeder lamps, that is to say, lamps in which a pencil of carbon was capable of being fed up so as to compensate for its destruction by the current?

Ans. No, sir, not at 94 Walker street.

1750 X Int. 76. Have you no recollection of any such lamps at 94 Walker street?

Ans. No, sir.

X Int. 77. Have you no knowledge of their use there in any way?

Ans. No, sir.

— Int. 78. And never heard of their being used there?

Ans. No, sir.

— Int. 79. After the time you began to fill lamps at 40 Broadway how frequently were you at 49 Walker street?

Ans. Quite frequently; that is to say, in one week I might be up there a dozen times, and another week three or four times.

X Int. 80. What would take you up there?

Ans. In some instances my desire to see how the lamps were progressing and burning, and in other cases Mr. Man and Mr. Sawyer would sometimes send for me.

X Int. 81. How long would you remain there?

Ans. Various lengths of time, from a few minutes to sometimes two or three hours.

X Int. 82. How many times are you certain you remained there as long as two or three hours?

Ans. It is impossible to state positively. Probably fifteen times.

X Int. 83. Are you certain that you filled any lamps for Mr. Sawyer after March 20th, '79? I mean as to Walker street.

Ans. I am not positive in regard to that particular date. It was about that time, or a little later, my impression is, they moved to Ansonia.

X Int. 84. In what condition were the lamps brought to you for filling at 40 Broadway?

Ans. All ready to set up in the circuit for filling with nitrogen gas. A few at times being exhausted at the Walker-street shop, and others not exhausted.

X Int. 85. By exhausted, what do you mean?

Ans. The air being taken out from the lamps.

1751 X Int. 86. Do I understand you that you would arrange these lamps on the stand L, in connection with your apparatus shown in your sketches, and fill them with nitrogen gas?

Ans. Yes, sir.

X Int. 87. And the general principle of your apparatus was by means of a suitable water suction to draw nitrogen gas through a series of tubes or bottles containing chemicals, thereby purifying the gas, or depriving it of moisture. Is that so?

Ans. It is.

X Int. 88. You have mentioned that in certain lamps you had to insert tubes into the lamps for the purpose of filling the same with nitrogen gas in such manner that one of the tubes should extend to the upper end of the lamp globe while the other should be shorter, terminating near the base of the globe. Please state the object of this so that the court may understand it.

Ans. The extension of the tube to the end of the lamp was for the purpose of allowing the nitrogen to more thoroughly permeate every part of the lamp while the latter was being filled.

X Int. 89. If the tubes had been short, terminating near the base of the lamp would it not have been almost impossible in tubes of the diameter and length you described as used for the lamps to have got rid of the air at the end furthest removed from the base?

Ans. I think not, but there would be a much longer time occupied in making this displacement.

X Int. 90. And with an ordinary aspirator such as you used very much longer time, would it not?

Ans. The length of time is dependant upon the rapidity of the gas.

X Int. 91. Putting it in another way, the consumption of nitrogen gas in order to arrive at the filling of the globe with nitrogen would be very much greater with the *the* short tubes, would it not?

1752 Ans. It would.

X Int. 92. In those lamps in which the metal conductors or radiators were tubular, I understood you to say that some provision was made so that the tubular conductor *the* acted instead of the long tube you otherwise inserted in the lamp. What arrangement was made?

Ans. One of the conductors was hollow from the bsse to the top, passing through the bottom of the lamp and containing at its lower end a cock turned by means of a screw-driver. Rubber tubing connecting the lamp with the system for purifying nitrogen gas was attached to the base of this tube and securely fastened, but not far enough up on the tube to cover the cock which was turned by the screw-driver. By this arrangement the lamp could be securely shut off without being taken out of the system.

X Int. 93. And when this hollow conductor did not exist, how did you insert the long glass tube for the purpose of filling the globe with nitrogen gas?

Ans. The metallic tube was passed up through the base of the lamp, fitting the tube in which the cock was placed loosely, the lower end of this tube passing into the rubber tubing, the rubber tubing itself being joined to the metal-ic tube which held the stop-cock at the base of the lamp. When the lamps were filled with nitrogen this tube was withdrawn from the lamp, and allowed to pass down through the aperture at the base of the lamp into the rubber tube, and the instant it passed the stop-cock, that was turned. The rubber tube was larger than the inner metal tube so that I could work the metal tube down into the rubber.

X Int. 94. What sort of a stop-cock was there to the base of the lamp?

Ans. It was a metallic cock: Further than that I have forgotten the details of construction.

X Int. 95. How far were the lamps put together which you received at 40 Broadway?

1753 Ans. The interior of the lamp was in complete order for running, so that no further change was necessary after the lamps were filled.

X Int. 96. Were the globes fastened to the base? If so, how?

Ans. The globes were fastened to the base first by having the surfaces of the glass plate evenly ground and Canada balsam placed between to fasten them together, and then long screws running from the upper flange of the base of the globe through to the lower glass plate and there secured.

X Int. 97. Were metal rings or flanges used above or below the base of the lamp?

Ans. I think there were—yes, sir.

X Int. 98. In other words the lamps were intended to be ready for filling. Is that so?

Ans. Yes, sir.

X Int. 99. And this was the case with all lamps sent to you at 40 Broadway, was it not?

Ans. That was the condition of all lamps sent down to 40 Broadway to be filled. There were a few lamps sent down to me, however, to examine the carbons, generally by Mr. Man, who claimed that the lamps were not properly filled. That is to say, taking two lamps from one set which had been filled at the same time, two of any particular kind, as straight pencil or arch carbon, one lamp would burn well and the other poorly when tested with several hours' run at the shop, and yet no apparent difference could have been noticed in those lamps when filled.

X Int. 100. In filling the lamps, did you ever open them, or were they kept closed?

Ans. They were always kept closed.

X Int. 101. After the lamps were filled by you, what did you do to them?

Ans. After turning the stop-cocks I soldered the stop-cocks, some of them with solder and some with sealing wax, as required by Mr. Sawyer.

X Int. 102. Did you put the lamps into their cups?

1754 Ans. Not at 40 Broadway. I have no recollection of doing it.

X Int. 103. So that all you had was the globe, the base fastenings, and the interior works. Is that so?

Ans. In a few instances I sealed the lamps besides the stop-cocks by pouring a mixture of sealing-wax, ca-utchouc around the base of the lamp, but did not set it in the metal cup.

X Int. 104. In testing the lamps, how many battery cells did you employ?

Ans. I had a large three-cell, bichromate dip battery, sufficient to bring each lamp in circuit to low incandescence.

X Int. 105. Was this bichromate battery what you have called a Ladd cell?

Ans. It is not. Mr. Fuller had a few Ladd cells there, which were used on a few of the lamps first sent down. But the battery did not work satisfactorily being an old one, and I purchased us a new one.

X Int. 106. What degree of incandescence did you raise the lamps to?

Ans. Till the carbon became at a low red-heat not sufficient to give any light.

X Int. 107. Was this the case when you used the Ladd cells and the bichromate battery?

Ans. We had difficulty with the Ladd cells, and for that reason did not use them, except in the few instances stated.

X Int. 108. Do you mean that the Ladd cells were not so powerful as the bichromate battery?

Ans. No, I mean that at times the Ladd cells would operate and not operate, without apparent reason.

X Int. 109. When the lamps were filled and tested by you, what was done to them by you?

Ans. They were laid carefully aside, and either sent up to the factory or they sent down for them; generally, however, they sent down for the lamps.

1755 X Int. 110. Why were they laid carefully aside?

Ans. For the reason that they were made of glass, required careful handling.

X Int. 111. Except as you visited 94 Walker street, had you any personal knowledge as to what was done to these lamps after they left your hands?

Ans. No, sir.

X Int. 112. When a lamp or carbon proved defective under your test, what did you do, if anything, to it?

Ans. I returned it to the factory as unfit for trial at the factory.

Adjourned to meet on Wednesday, April 3d, at 10 o'clock, a. m.

New York, *April 3rd*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

X Int. 113. Am I right in understanding by your answer to question 41, that when you used the mercury tubes there mentioned, it was for the purpose of exhausting the air, preparatory to filling the lamps with nitrogen?

Ans. Yes, sir.

X Int. 114. When you exhausted the lamps slightly so as to allow for the expansion of the gas when the carbon was rendered incandescent, did you have any uniform gauge or test, or did you make simply a slight exhaustion without definite accuracy?

Ans. The safety tube in the aspirator at the end of the apparatus I used as an indicator for a slight exhaust, the lowering or falling of the column of water in the tube indicating whether the gas was under pressure or under a slight exhaust. The meniscus of the water in the safety tube, which at normal pressure is slightly above the pressure in the aspirator, I would bring down to the level of the water in the aspirator.

1756 X Int. 115. As I understand you, the exhaust was a very slight one, was it not?

Ans. Yes, sir.

X Int. 116. In sending the lamps to 94 Walker street, did you put any tag or marks upon the lamps?

Ans. Only in the case of lamps which failed to stand the test of incandescence. I had no uniform tag; in some instances a note was sent describing the lamp which worked unsatisfactorily, the description in the note being sufficient to enable the parties at the factory to recognize the lamp spoken of.

X Int. 117. When a carbon proved defective, what, to your knowledge, was the practice of the factory? was the lamp thrown away, or the lamp taken apart and a new carbon substituted?

Ans. Generally speaking the lamp was taken apart and a new carbon inserted. In some instances, however, some of the lamps were not set up again.

X Int. 118. When the carbon was replaced were the lamps refilled before being again used?

Ans. Yes, sir, the lamps were brought down to be filled under the same conditions as before, unless the carbon of a different form than the former one had been inserted.

X Int. 119. And if the carbon had been changed the lamp so changed was sent to be filled, was it not?

Ans. It was, and the lamp might be considered as an entirely new lamp so far as the carbon was concerned.

X Int. 120. What means, of your own knowledge, had you of knowing whether, for example, a lamp sent January 14 was the same or a different lamp from a similar appearing lamp sent, say, two weeks before?

Ans. In the case of lamps which I had filled and sent to the factory and which ran there but a short time and then broke, it is probable my attention was not called to the matter; but whenever
a lamp made an especially long run the lamp after breaking
1757 would be fitted with a similar carbon to the one which make
the long run, and in some instances a note to that effect from
Mr. Sawyer would be sent to me.

X Int. 121. As I understand you, as a general rule, you did not then know whether the lamps sent to you for filling were the old lamps with new carbons or fresh lamps which had not been before filled?

Ans. In some instances where a carbon had been consumed at the factory in running the lamp an apparent change would take place in the appearance of the metallic conductor; that is to say, the upper portions of the conductors would have a different appearance in color than the lower portions.

X Int. 122. That is to say that in some instances the discoloration of the metal conductors showed to you that the lamp had been in use before?

Ans. Yes, sir.

X Int. 123. Where this discoloration did not exist, or where, for example, it may have been removed by cleaning the conductors, had you any means of identifying a particular lamp with a similar appearing lamp previously sent to you?

Ans. Two lamps of the same size, construction and appearance, would give me no indication to distinguish between a new lamp and an old one. That is to say, if the lamp which had been previously filled had been thoroughly cleaned and the wax or sealing material used at the base of the lamps entirely removed, there would be no distinction; but, in nearly every instance, portions of the sealing material on the outside of the lamp would be left upon the base of the globe, these proportions being very small as a rule.

X Int. 126. And these remains of the sealing wax existing, as you say, in nearly every instance enable you to say that the lamp had been used before. Is that so?

Ans. Yes, sir.

X Int. 127. Do I understand you rightly that in nearly every instance the lamps sent to you showed such traces of sealing wax?

1758 Ans. Traces of sealing wax or of the other material they used for sealing the outside of the lamps.

X Int. 127½. Do you remember what your charge was for filling lamps at 40 Broadway?

Ans. No, sir, I do not.

X Int. 128. Do you think it was in the neighborhood of eighty cents per lamp?

Ans. It would be impossible to answer that question, as I have no memoranda or recollection about it.

X Int. 129. You presented a record kept by Mr. Fuller and yourself of some twenty-two lamps. In your recollection is that record a fair illustration of your experience with the lamps you filled at 40 Broadway?

Ans. I do not think so for the reason that these were the lamps first filled at my laboratory, and later on with experience the work was more satisfactory.

X Int. 130. As I understand you, you had been filling lamps at 94 Walker street with the same apparatus you used at 40 Broadway?

Ans. Yes, practically the same apparatus. I took the apparatus down to 40 Broadway, but it was returned before the company went to Ansonia. I duplicated the apparatus at my laboratory.

X Int. 131. How did your apparatus differ from the apparatus at Walker street prior to the use of your method?

Ans. The improvements that I made after going to the factory consisted in the use of phosphoric anhydride as a drying agent, and in the use of metallic sodium kept in a melted condition to absorb all traces of oxygen from the gas. I also inserted the drying tubes marked "K" in Stillman Exhibit No. 2.

X Int. 132. State what means were used prior to your method for preparing and purifying the gas.

Ans. The method used was by heating a mixture of chloride of am-onium and potassium nitrite with sufficient water, and passing the volume of nitrogen gas through the system of purifiers
1759 marked Stillman No. 1. The reason that I introduced phosphoric anhydride was because I was under the impression that the gas made by the process described in Stillman No. 1 was not sufficiently free from moisture and air.

X Int. 133. Do I understand you that your figure 1 represents the entire apparatus used at Walker street before your improvement?

Ans. Yes, sir.

X Int. 134. And the only substance in that apparatus tending to free the nitrogen from oxygen existing in the original air of the retort or entering by any leak was the bottle of pyrogallate of sodium?

Ans. Yes.

X Int. 135. The use of the cotton was simply to prevent the mechanical transportation of particles of dust or solid matter, was it not?

Ans. Yes.

X Int. 136. The sulphuric acid tending to absorb moisture?

Ans. Yes, sir; and the ferrous sulphate to absorb any traces of oxide of nitrogen which might have been formed by overheating the retort.

X Int. 137. After the gas was so prepared what means, if any, were used for purifying it before it was passed into the lamps?

Ans. The nitrogen gas was passed through another set of Wolff bottles containing a solution of sulphate of iron, then solution of caustic potash, then oil of vitr-ol, each solution being in two different Wolff bottles joined consecutively.

X Int. 138. What was the trouble, if any, with this apparatus which resulted in the use of your apparatus?

Ans. The original cause of the trouble I never was made conversant with except that Mr. Sawyer and Mr. Man were under the impression that trace of moisture was in the nitrogen gas after it was in the lamps, and the problem as stated to me was to
1760 deprive this nitrogen gas of all traces of moisture. This, I found, could be done by the use of phosphoric anhydride which, if I recollect right, I took out a patent for.

X Int. 139. What, from your experience, would be the effect upon the life of the lamp of the presence of traces of moisture in the nitrogen gas?

Ans. I think that moisture in the nitrogen gas in the globe when brought in contact with the incandescent carbon at a white heat, would be converted into oxygen and hydrogen. This dissociation if once taken place the oxygen would be free to unite with the carbon to form carbonic acid and the pencil speedily destroyed.

X Int. 140. And this it was the object of your invention or use of the phosphoric anhydride to prevent?

Ans. Yes, sir; the phosphoric anhydride was used to prevent the presence of moisture in the lamps in conjunction with the other dryers.

X Int. 141. You stated that after you began filling at 40 Broadway that later on with experience the work was more satisfactory. What do you mean by that?

Ans. I mean, first, that the experience showed that speed in filling was an essential, and also the experience of working in the shop producing a better contact of the carbons.

X Int. 142. Do I understand that you mean by speed in filling that the lamps had to be filled and sealed very quickly, or that you had to have a very rapid flow of nitrogen throuh the lamps in order to sweep out the air?

Ans. No, sir. The speed spoken of refers to the passage of the gas through the purifying apparatus, the absorption of impu-ties being more perfect at a slow rate of speed than fast. I would say right here that when I substituted a cylindrical glass vessel for holding the sodium, the latter being placed on a sand bath, if the rate of flow of the gas was too fast, or if the gas had not been properly purified from oxygen the metallic sodium would catch fire. 1761 Of course this would only take place when there happened to be oxygen in the gas.

X Int. 143. Is it a matter of easy practice or a matter requiring considerable experience to prepare and purify nitrogen gas so as to deprive it of oxygen, either alone or in combination, and from moisture?

Ans. Taking the text books on chemistry as a standard, the process is a simple one and not difficult; but to deprive the nitrogen of the last traces of oxygen the use of sodium, as above indicated, is essential in my mind, which does not necessarily complicate the apparatus materially, and in a chemist's hands a simple operation.

X Int. 144. In your answer to question 14 you mentioned the straight Carré carbon as used by Sawyer and Man. What kind of a carbon was that and in what shape was it used?

Ans. It was a carbon called the Carré carbon, imported from Paris, and was used in all the different forms of the carbon pencils, except the arch, which was a paper carbon. It was retort carbon. I knew they ran out of it once and had to cable over.

X Int. 145. What kind of a carbon was the hollow willow carbon mentioned by you in the same answer to question 14.

Ans. It was a straight cylindrical hollow carbon made from willow.

X Int. 146. You state that the carbon was hollow. What had been removed to make the carbon hollow.

Ans. The interior carbon had been removed by mechanical means.

X Int. 147. I ask you to read on page- 70 and 71 of Sawyer's book on electric lighting, already in evidence, beginning on page 70 where the description of boat-shaped carbons is commenced, and state whether the hollow willow carbons mentioned by you are the same or different from the carbons there mentioned in the book?

Ans. They are different. The hollow willow carbon
1762 being a hollow cylinder, whereas the boat-shaped carbon
is a straight pencil, concavo-convex in cross-section, the
centre of the carben being slightly larger than the base.

X Int. 148. How much, if any, of the original willow was left in these hollow willow carbons as you call them?

Ans. I could not answer that. I didn't make the carbons.

X Int. 149. How did you know that they were hollow willow carbons?

Ans. Nearly every lamp sent down to be filled was sent with a note describing the lamp. At the factory, before I filled the lamps at 40 Broadway, the lamps when running after being filled with the gas were subject to close examination by Mr. Sawyer and Mr. Man, myself and others who were interested, and the proficiency of the lamp always made a discussion as to the different forms of carbon which would be described at that particular time while the lamp was running.

X Int. 149½. What do you mean by the expression "treated" in your answer to question 14?

Ans. Mr. Sawyer had a process of depositing carbon in a very fine state of division upon pencils of coarser material by decomposition of hydrocarbon, this coating being very hard and uniform. The term "treated" referred to a carbon which had thus been exposed to this process.

X Int. 150. What do you mean by the expression "pencils of coarser material" in your last answer?

Ans. I mean carbon, the particles of which were coarser than the carbon deposited by the process.

Adjourned until April 4th, 1889, at 10 o'clock a. m.

NEW YORK, *April 4th*, 1889—10 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

1763 X Int. 151. What do you mean by the term "plain arch"
in your answer to question 14?

Ans. That simply refers to the arch-shaped carbon which was plain in its appearance. My impression is that there were a very few carbons made of the arch form from hard carbon, by one of the men in the shop; but by the plain arch I understand the paper carbon.

X Int. 152. Is there any difference between your use of the term "plain arch" and your use of the term "horseshoe paper carbon" in question 14?

Ans. No, sir.

X Int. 153. In your record of lamp tests under date of January 9th there is an entry of one lamp as No. 2 crescent. What form do you recollect as indicated by that term?

Ans. The same form as the arch, that being a term of my own used at that time.

X Int. 154. In the hammer-and-anvil lamps, what class of carbon was used?

Ans. Straight-pencil carbon, both treated and untreated. The kind of carbon was both hard carbon and willow carbon, so far as I recollect. I am positive these two materials were used.

X Int. 155. In your answer to question 46 you state that several of the lamps burned finely for a number of days. Do you know of your own knowledge what was the material of the carbon in these several lamps?

Ans. My knowledge concerning the carbon in these lamps is the same as of the others.

X Int. 156. Are you able to swear that any one of the several lamps mentioned by you in your 46th answer were paper carbons?

Ans. My knowledge relating to the paper carbon would be the same as that relating to the other carbon, and the lamps could not burn successfully at the factory without being filled with nitrogen gas by me at that time. I was therefore cognizant of all the 1764 forms of carbon in the lamps which were filled. Some of the lamps which burned successfully were of paper arch form.

X Int. 157. Do I understand that you substantially filled all the lamps during the period you were employed to fill the lamps?

Ans. Yes, sir.

X Int. 158. How old a man was Mr. Myers at this time?

Ans. About twenty years, I should judge—about twenty or twenty-one.

X Int. 159. How did you come to testify in this suit?

Ans. President Morton of the Stevens institute told me that the Westinghouse Company desired me to fill some of the old form of Sawyer lamps with nitrogen gas and that I should get ready to do the same by getting the apparatus together, as the lamps would be ready for charging in a few days, and in the course of a conversation which I had with him, it appeared to him that my former work in this line would be of interest to the company.

X Int. 160. Were the lamps brought to you to be filled?

Ans. They were not; I expect them any moment at the institute.

X Int. 161. Were you in any way retained by the Westinghouse Company?

Ans. President Morton secured my services for the Westinghouse people as expert in the filling of the globes with nitrogen.

X Int. 162. Do you expect to be called in this suit as an expert?

Ans. I do.

X Int. 163. How long ago was it Professor Morton spoke to you?

Ans. Ten days or two weeks, about, I should say.

1765 Redirect examination by Mr. KERR:

R. D. Int. 164. Please state where the chemical apparatus was placed in the Walker-street shop?

Ans. It was placed on the bench—a portion of it—and the dryers and purifiers on the partition in the shop between the front and back rooms. There was a table against the partition, and sometimes the generating apparatus was placed on the table and sometimes it was upon the adjacent end of the workmen's bench.

THOMAS B. STILLMAN.

Examination closed.

COMPLAINANT'S EXHIBIT SAWYER-STILLMAN LETTER OF MARCH 5, 1879. W. T. F., Examiner, April 2, 1889.

MARCH 5.

Friend STILLMAN:

I send you 5 lamps which please have ready for us by 9 to-morrow. To-morrow will send you 4 more.

Seal these as before excepting the stop-cocks. With these fill the cups with melted sealing wax or shellac and screw on, instead of soldering. Be careful when you put the sealing wax originally on the base not to have it come up in way of the cups for the stop-cocks.

Be sure to run these lamps long enough to get a good filling.

Yours truly, W. E. SAWYER.

Shall I send down for the lamps to-morrow morning, or will you bring them up?

1766 NEW YORK, *April 1st*, 1889.

Met pursuant to arrangement of counsel.

Present: Amos Broadnax, Esq., for complainant and Mr. Man; and Mr. Walter K. Griffin, for defendant.

IDA MAN IVES, being called on behalf of complainant and duly sworn, testifies as follows:

Int. 1. What is your name, age, residence and occupation?

Ans. Ida Man Ives. 33 years of age. I reside with my husband and father at 118 Putnam avenue, Brooklyn. My father's name is Mr. Albon Man. My husband's name is Edward M. Ives.

Int. 2. Where were you residing in the winter, spring, summer, fall of 1878 and winter of 1879?

Ans. With my father at his residence, 118 Putnam avenue, Brooklyn.

Int. 3. During that time do you recollect of Mr. Wm. E. Sawyer's visiting your father at his residence?

Ans. I do.

Int. 4. When first did he visit your father there?

Ans. In the latter part of the winter or spring of 1878.

Int. 5. Did he visit your father any time during the summer or fall of 1878?

Ans. He was there during the fall of 1878.

Int. 6. State, if you recollect, how often he called to visit your father?

Ans. I don't recollect how often. He was there a number of times, and I recollect his dining there once.

Int. 7. State whether or not you recollect of your father's making any carbons in his house there at any time during the time mentioned by you?

Ans. Yes, I recollect seeing him in the spring of 1878 making some carbons. That is what he said he was making.

Int. 8. State what, if anything, you saw him do towards the making of such carbons?

1767 Ans. I saw him put in little sticks and also pieces of paper in strips and rings—put them in a crucible and place that in the fire.

Int. 9. What fire did he put them in?

Ans. In the range fire in the kitchen, and also in the laundry stove.

Int. 10. State what, if anything, he put into the crucibles besides the paper and sticks?

Ans. Some black-looking powder.

Int. 11. Do you know what the black-looking powder was?

Ans. I do not.

Int. 12. How often did you see your father do this?

Ans. As near as I recollect, twenty or thirty times.

Int. 13. What, if any part, did you take in assisting him to prepare the paper and sticks that he put in the crucible?

Ans. I cut out the papers for him, and I saw him filing the sticks fine, smoothing them down.

Int. 14. Did you assist him in that?

Ans. I didn't do it—simply saw him.

Int. 15. What shape were the papers that you cut out for your father?

Ans. In strips about an eighth of a yard long—different widths and in rings.

Int. 16. What kind of paper was it that you cut up for your father in those shapes?

Ans. Blotting paper.

Int. 17. What kind of blotting paper was it?

Ans. Ordinary white blotting paper, as I remember it.

Int. 18. Do you recollect of cutting up any other kind of paper?

Ans. No, sir.

Int. 19. About how wide were the strips of white blotting paper that you cut up for your father?

1768 Ans. Very narrow little fine strips perhaps about an eighth or a quarter of an inch.

Int. 20. About what size were the rings of paper that you cut out for your father?

Ans. About the size of an ordinary spool of thread—the end of it.

Int. 21. How long did these experiments of your father continue from the time he began?

Ans. Several weeks.

Int. 22. What was the crucible like that he put the carbons in that he put in the furnace of the range?

Ans. I did not examine it. I think it might have been metal of some kind.

Int. 23. Was it square or round? By round I mean cylindrical or conical.

Ans. Round.

Int. 24. Do you recollect of seeing him use a square crucible or box? If so, please to state whether it had a lid or how it was fastened.

Ans. Yes, I recollect of his using a square box of sheet iron or something of that kind, and he fastened the lid on by winding a wire or something of that kind, as I recollect.

Int. 25. State, if you know, what these carbons were being made for by your father.

Ans. For his electric light.

Int. 26. Did your father tell you that at the time, or did you see them used in electric lamps?

Ans. He said he was making carbons. I saw the lights afterwards.

Int. 27. Where did you see the lights?

Ans. At his shop in Walker street, New York.

Int. 28. How many of the lights did you see there?

Ans. Five or six.

Int. 29. All burning at one time?

Ans. Yes, they were all burning at one time and turned on to different degrees of brightness.

1769 Int. 30. What shape were the carbons that were in those lamps that you saw?

Ans. A little longer than a half circle.

Int. 31. Do you know whether or not any of these carbons were made of paper or sticks of wood such as you made for your father? State what your recollection of it is.

Ans. I do not know what they were, positively. I simply know what I was told.

Int. 32. State what your father told you about it at the time.

Ans. All I know is that he told me the carbons were the same in the lamps as those that he made.

Int 33. State, if you recollect, whether or not you saw your father tie up any of the sticks that you or he prepared in the form of a bow or loop before he carbonized them?

Objected to as distinctly leading. Question withdrawn.

Int. 34. State, if you recollect, in what form your father put the sticks before putting them in the crucible that had been previously prepared by you or him?

Ans. They were straight, as I recollect.

Int. 35. How did you happen to visit your father's shop in Walker street?

Ans. He took me there with a party of friends to show us the lamp.

Int. 36. With whom was your father working at that time on electric lights?

Ans. With Mr. Sawyer.

Int. 37. What time was it that you visited the shop in Walker street? When was it?

Ans. In the fall of 1878.

Int. 38. Who went with you besides your father?

Ans. My aunt, Miss Watkins, and Mr. and Mrs. Greenough, of northern New York.

Cross-examination:

X Int. 39. Can you state any more distinctly when you visited the Walker-street shop?

1770 Ans. I can't remember exactly. It was early in the fall.

X Int. 40. How long was it after you had assisted your father as to the carbons?

Ans. It must have been four months, perhaps. It was early in the spring, March or April, when I assisted him. It was certainly September when I went to the shop, or later.

X Int. 41. What other shapes did you see at the shop, if any, besides the half circles?

Ans. I do not recollect any.

X Int. 42. Did you not see straight carbons?

Ans. I do not recollect.

X Int. 43. How long were you in the shop?

Ans. About half an hour, I think, perhaps longer. I don't know the exact time.

X Int. 44. And you think you saw about a half dozen lamps?

Ans. Yes.

X Int. 45. And you didn't see any straight carbons?

Ans. I do not recollect any.

X Int. 46. How do you come to recollect the shape of the carbons at all?

Ans. Same as I recollect anything. I recollect it, that they were of that shape.

X Int. 47. What part of the shop were you in?

Ans. In the reception-room and in the workshop.

X Int. 48. What kind of lamps were those that you saw at the shop?

Ans. They were a little glass globe—oblong globe—little fine-looking wire inside the globe so far as I could see, with a band around the small end of the globe, and they were mounted on a bracket of some kind, I don't know exactly what.

X Int. 49. What did your father say to you, exactly, so near as you can now remember, as to the carbons?

Ans. Nothing that I recollect, except that he was making carbons.

1771 X Int. 50. That was at your house, was it not?

A. Yes.

X Int. 51. Who was in charge of the kitchen at the time?

Ans. My aunt, Miss Watkins.

X Int. 52. Who was the cook?

Ans. I can't recollect exactly. We changed girls several times. There was a girl there.

X Int. 53. Did not the same girl who was there in 1878 remain there for several years afterwards?

Ans. No.

X Int. 54. How did you come to testify here? I mean who first spoke to you as to the matter?

A. I spoke first to my father.

IDA MAN IVES.

1772 *Testimony of Alice J. Watkins.*

ALICE J. WATKINS being called in behalf of complainant, and duly sworn, testifies as follows:

Int. 1. What is your name, age, residence, and occupation?

Ans. Alice J. Watkins, 44 years of age. I reside at 118 Putnam avenue, Brooklyn, in the family of Mr. Albon Man. His wife is my sister.

Int. 2. Have you been present and listened to the testimony of your niece, Mrs. Ives, here this afternoon?

Ans. Yes.

Int. 3. Please to state what, if anything, you recollect about the experiments of Mr. Man in making carbons at his house, and when it was that such carbons were made?

Ans. It was in the winter and spring of 1878, he worked in the kitchen, and I remember his using a dish he called a crucible. It was a rough-looking vessel, I thought of iron. In it I saw him put bits of paper, pieces of sticks, a blackened powdered substance. That is all I can recall. I saw him cover it and place it in the fire in the range. I don't know that I can recall any more in regard to it.

Int. 4. What was the shape of the crucible, as near as you can recollect it?

Ans. Round.

Int. 5. How long did he leave it in the furnace of the range or other stove?

Ans. I don't recollect.

Int. 6. Did you see him have more than one crucible?

Ans. I think so.

Int. 7. How many do you recollect of his having?

Ans. Not more than two.

Int. 8. Were they both of the same shape?

Ans. The other was square.

Int. 9. Did they both look like iron or clay?

Ans. I think so.

1773 Int. 10. State if you recollect what the shape of the paper and sticks were that he put in the crucible?

Ans. The paper was in narrow strips an eighth of a yard long.

Int. 11. Were there any shapes of the paper?

Ans. I think in round rings.

Int. 12. Can you give the size of the rings as near as you can recollect?

Ans. No, I can't.

Int. 13. What was the shape of the sticks?

Ans. As I remember, they were straight—of different lengths.

Int. 14. How often did you see him prepare these papers and put them in the crucibles?

Ans. Twenty or thirty times. I have a distinct recollection of his cutting the sticks, I meant to say preparing them.

Int. 15. What makes you recollect the fact of his making these carbons?

Ans. The amount of dirt and refuse I had to clean.

Int. 16. Did you have charge of the housekeeping or kitchen department then?

Ans. Mostly.

Int. 17. Did you visit the shop in Walker street along with Mrs. Ives and Mr. Man?

Ans. I did.

Int. 18. What did you see there?

Ans. I saw the electric lamp.

Int. 19. How many do you recollect of seeing on that occasion?

Ans. Five or six.

Int. 20. Did you notice the form of the carbon burners in the lamp? If so, please to state what the form of the carbon burners was?

Ans. A little longer than half a circle, as I recall it.

Int. 21. Did you notice whether any of the burners in those lamps were made of straight sticks of carbon?

Ans. I do not recall it.

1774 Int. 22. Do you recollect of Mr. Sawyer visiting Mr. Man's house?

Ans. I do.

Int. 23. State, if you recollect when his visits occurred.

Ans. The early spring, I think, and then in the summer, of 1878.

Int. 25. How often did he visit there?

Ans. I can't remember, maybe six times.

Int. 26. Can you recollect what time in the year it was in 1878 that you visited the shop in Walker street?

Ans. In the fall; it may have been September, somewhere about that.

Int. 27. These carbons that you saw in the lamps—I mean the carbon burners you saw in the lamps in the Walker-street shop, how did they differ, if at all, from the paper carbons you saw Mr. Man make at his house?

(Objected to as leading and suggestive.)

Ans. I should think as near as I can recall it they were the same shape.

Cross-examination:

X Int. 28. Were these lamps lit when you saw them?

Ans. They were.

X Int. 29. Who lit them for you to see?

Ans. I think they were lighted when we went there.

X Int. 30. Were they kept lit?

Ans. Yes.

X Int. 31. All the while you were there?

Ans. They were turned up and down to show different degrees of light.

X Int. 32. As I understand you they remained lighted all the time you were there?

Ans. Yes.

X Int. 33. Are you sure your visit was made before October, 1878?

1775 Ans. I think so.

X Int. 34. Are you sure you did not see lamps with straight pencils?

Ans. I said I did not recall them.

X Int. 35. You simply do not recollect them, if they were there. Is that so?

Ans. Just as I said, I do not recall them.

ALICE J. WATKINS.

The further examination of the witnesses herein adjourned till Tuesday, 2d inst., at 1 p. m.

1776 NEW YORK, *April 5th*, 1889—10 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

Testimony of Hans J. Muller.

HANS J. MULLER, a witness on the part of the complainant, being duly sworn, deposes as follows in answer to interrogatories by Mr. KERR:

Int. 1. State your name, age, residence, and occupation.

Ans. Hans J. Muller; age, 51; residence, 553 West 53rd street; electrician.

Int. 2. Were you acquainted with William E. Sawyer, and if so, when did you become acquainted with him?

Ans. I was. I met him first in Arnoux & Hochhausen's shop, on the corner of Reade and Centre street, in the earlier part of 1878.

Int. 3. Were you connected with Arnoux & Hochhausen in any way?

Ans. Yes. I was foreman in the firm at that time.

Int. 4. Under what circumstances did you meet Sawyer?

Ans. He came to Hochhausen's office to order a machine, special wound, for a test of incandescent lights.

Int. 5. Of whose manufacture was that machine, and who made the special winding?

Ans. The machine was Hochhausen's manufacture of the old Siemens type, and I personally did the winding.

Int. 6. Was that machine used by Sawyer?

Ans. Yes, sir.

Int. 7. Where?

Ans. In a room at 41 or 43 Centre street.

Int. 8. Did you ever see any of the lamps which he tested with that machine?

1777 Ans. I have seen some of them a number of times. The first that I have seen was in 41 or 43 Centre street.

Int. 9. Please state at what time you saw the lamp at 41 or 43 Centre street and describe the lamp which you saw there.

Ans. It was in March or April, I rather think in March. The lamp consisted of a glass globe about six inches high, and an inch and a half diameter, mounted on a metallic base. As far as I could see from the distance that I was away from the lamp, there was a round carbon about three-quarters of an inch long and about a sixteenth of an inch thick mounted on two brass rods running up from the base to the upper part of the globe.

Int. 11. Was this carbon straight or curved?

Ans. It was straight and in a horizontal direction from one rod to the other.

Int. 12. How often were you at Sawyer's room at Center street?

Ans. I was there only one time to my recollection.

Int. 13. Did you ever see any of these lamps at any other place? and if so, where?

Ans. I have seen some on corner of Howard and Centre streets, in the period between May and earlier part of August, 1878.

Int. 14. Please describe the lamps you saw at Howard and Centre streets.

Ans. They had about the same shape as the one before described, with the exception that some had semicircular carbons, and in others the carbons were straight. They were placed vertically from one rod to the other.

Int. 15. Did you ever see these lamps in use at Howard and Center streets?

Ans. Yes, sir; I have seen two burning at the time on several occasions.

Int. 16. What was the form of the carbons in the lamps you saw burning?

Ans. Sometimes the form was semicircular, and sometimes the horizontal straight. Vertical-placed carbons I have not seen burning.

1778 Int. 17. How did those lamps you saw burning seem to operate?

Ans. They gave a very steady light as long as I saw them.

Int. 18. How was it as to brightness?

Ans. I judged they must have been about 12 to 16 candles.

Int. 19. How did you come to be at Howard and Centre streets?

Ans. Arnoux & Hochhausen had moved their shop on the 1st of May to that place, and I, of course, went with them.

Int. 20. Where was Sawyer's shop with relation to Arnoux & Hochhausen's shop at Howard and Center streets?

Ans. It was on the floor below—that occupied by Arnoux & Hochhausen, in a room occupied by a party named Mueller & Neumann.

Int. 21. Are you acquainted with Albon Man, and if so, when did you first become acquainted with him?

Ans. I am. I met him first in the earlier part of 1879, at 138 Center street, where he collected rent for a room occupied by Kaschau Brothers and myself.

Int. 22. Did you do any work for Sawyer when he was at Howard and Centre streets?

Ans. I did. One time I made a submarine lamp for them; another time I made a commutator, and another time I drilled brass rods to form cylinders, as he said, for the purpose of making certain lamps.

Int. 23. Was any work done for him by Arnoux & Hochhausen at Howard and Center streets besides this work you have spoken of in your last answer?

Ans. Yes, sir; but to my knowledge, the year previous. Whether there was any work done by them at that time I cannot say.

Witness here states that he misunderstood questions 22
1779 and 23; thought they referred to when Sawyer came to me
at 138 Center street, was in 1879.

Int. 24. I now will repeat my question 22, in view of your explanation; did you do any work for Sawyer when he was at Howard and Center streets?

Ans. Yes, sir. I connected the machine that I have spoken of before, and which was located in Hochhausen's shop, to Sawyer's little office on the floor below, to transmit electricity from the machine to there. I personally did not do much else. They gave me a number of orders, which I turned over to men that were working under my supervision, although I made a few small parts for lamps for them.

Int. 25. What were these orders which you turned over to other men for?

Ans. They were, as far as I know, all for lamps. Closer explanation was never given to me. They gave me simply pencil sketches showing how the piece should look when done, but did not explain what purpose it was intended for.

Int. 26. Were they in the habit of explaining to you what they were doing?

Ans. No, sir; on the contrary, they kept all their ideas as secretly as possible, and all I have seen was on occasions which they could not control.

Int. 27. Do you know anything about any manufacture of carbons for electric lamps done by them?

Ans. They sawed carbon pencils out of retort carbon and filed them down, sometimes round and sometimes square, until they had the desired shape. One time I have seen old Sawyer turning a piece of carbon round and boring a hole in, and then he cut a piece of it down to form a ring which he then cut in two parts; one of them he mounted on one of the lamps. That's all I know that they did.

Int. 28. Were you ever consulted in regard to the manufacture of carbons for the lamps by any of them?

Ans. Yes, sir. Old Sawyer one time asked me if I know
1780 of any device to cut retort carbons to pencils in a cheaper
manner than they did at that time. I answered, the only way of which I knew would be to mount a number of copper discs on a mandril and set it on a lathe and cut with them the carbons by means of applying water and sand; but I also stated, that this would be a rather expensive way, because a great number of them would break and become useless.

Int. 29. What did old Sawyer say to that?

Ans. He said that this would be only to use these carbons for experiment. They intended to make carbons out of paper by cutting them out into the desired shape and carbonizing them.

Int. 30. What did you understand he meant by carbonizing paper?

Ans. I understood the usual way of carbonizing vegetables; that is, to close them in a hermetically closed vessel and bring them into a white heat.

Int. 31. Had you at that time any knowledge or experience in carbonizing vegetable materials?

Ans. Yes, sir. Some years before I made carbons for batteries in turning wood into a cylinder which I then put in a retort, surrounded by a carbon dust and brought it to a white heat, by which it carbonized to my satisfaction.

Int. 32. Did Sawyer run the machine at Howard and Centre streets constantly?

Ans. No, sir; it was only running from time to time, when they wanted to try lights.

Int. 33. How did they get the machine started and stopped when they wanted to use or discontinue its use?

Ans. While I was there they came up to me telling me to start it or to stop it, and sometimes they started and stopped it themselves.

Int. 34. Can you state how many lamps you saw altogether at Howard and Centre streets?

Ans. I don't think I saw more than six in a finished shape.
1781 Int. 35. Did you make parts for any more than that num-
ber of lamps?

Ans. There were parts made for more under my supervision, and old Sawyer had a few men working for himself at Hochhausen's floor to make parts of lamps.

Cross-examination:

X Int. 36. The work you refer to in your answer to question 22nd, was done by you in 1879, after you had moved to 138 Centre street; was it not?

Ans. Yes, sir.

X Int. 37. Where was Mr. Sawyer's office then, if you know?

Ans. At the corner of Elm and Walker streets.

X Int. 38. How large a room had Sawyer on Howard street?

Ans. About ten feet square to my recollection.

X Int. 39. Was there any machinery in it?

Ans. Outside of an air pump I don't know of any.

X Int. 40. Did any shafting run through it so as to apply power?

Ans. No, sir; not that I know of.

X Int. 41. In your answer to question 35 you state that old Sawyer had a few men working for himself at Hockhausen's floor. Was there more than one man working for him?

Ans. There was to my recollection three or four—sometimes three and sometimes four. One man named Sharp was engaged permanently at that time by Sawyer, and the rest were taken to help whenever he was in want of them.

X Int. 42. Do you remember the names of these men?

Ans. The name of one is Zagg, and the other Rector. A Frenchman did some work for him—I can't recollect his name.

1782 X Int. 43. How soon before Sawyer left Howard street did you have your conversation with old man Sawyer as to making carbons?

A. I don't know the time when Sawyer left Howard street, because I left before him. Old man Sawyer told me about making paper carbons in June or July, '78. I cannot locate the time any closer.

X Int. 44. In your answer to question 27, you say you saw old Sawyer turning a piece of carbon round and boring a hole in it. That was a piece of retort carbon, was it not?

Ans. Yes, sir.

X Int. 45. Did you see Mr. Man at Howard and Centre street-?

Ans. I cannot say, because I did not know him at that time, and if he has been there, my attention not being called to him personally.

X Int. 46. When work was being done for Sawyer it was done in Hochhausen's shop amongst the other men, was it not?

Ans. Yes; but not all, for as I already stated, one man was permanently engaged by Sawyer.

X Int. 47. But he worked in the same shop as the other man, did he not?

A. Yes, sir.

X Int. 48. How did you come to testify in this suit?

A. About 14 days *any* a gentleman, who introduced himself as being connected with Mr. Curtis, came up to our office, corner of 11th avenue acd 16th street, asking me if I had any knowledge about Mr. Sawyer and his doings at Howard and Centre streets. I answered yes, and then Mr. Curtis asked me to testify.

X Int. 49. How many times have you seen either Mr. Curtis or any one else as to the subject of your testimony?

Ans. I have seen Mr. Curtis only once, and the other gentleman twice; one time at our office and the other time at Mr. Curtis' office.

1783 X Int. 50. Were you ever at Sawyer's place at Elm and Walker streets?

A. Yes, sir; in the summer of 1879. It was at the time I did the work mentioned in my 22d answer.

(Signed) H. J. MUELLER.

Examination closed.

1784 New York, *April 5th*, 1889.

Met at 1 p. m., pursuant to adjournment.

Present: Mr. Broadnax for complainant, and W. K. Griffin, Esq., for defendant.

Deposition of Edwin L. Hayes.

Edwin L. Hayes, being called on behalf of complainant, and duly sworn, testifies as follows:

Int. 1. What is your name, age, residence and occupation?

Ans. Edwin L. Hayes; 69 years of age; I reside at Bloomfield, New Jersey; I am a general broker in lands, stocks and bonds.

Int. 2. Are you acquainted with Albon Man?

Ans. I am.

Int. 3. How long have you known him?

Ans. More than twenty years.

Int. 4. Have you ever been a neighbor of Mr. Man's?

Ans. Yes, sir. I lived next door but one to him in Putnam avenue, Brooklyn, for a number of years.

Int. 5. Were you a neighbor of his in the year 1878?

Ans. I was.

Int. 6. What, if anything, do you recollect of Mr. Man's telling you about carbons for electric lamps in 1878?

Ans. The conversation on carbons came up more particularly after I had introduced Mr. Sawyer to Mr. Man.

Int. 7. When was that?

Ans. That was in February or March, 1878.

Int. 8. When did you make the acquaintance of Mr. Sawyer?

Ans. In the latter part of December, 1877.

Int. 9. How did you make his acquaintance?

Ans. I was introduced to Mr. Sawyer by a gentleman of the name of Church.

Int. 10. What was the occasion of Mr. Church's introducing Mr. Sawyer to you?

1785 Ans. Mr. Church called upon me to know if I had any facilities for getting capital in to work upon electric lighting business.

Int. 11. What did you say to him in reply?

Ans. I said that I thought perhaps I had the means of getting capital in; that I had a friend in Brooklyn who had been giving attention to electric matters of various kinds, and thought perhaps I might interest him, I referred to Mr. Man.

Int. 12. Had you and Mr. Man previously talked together about the subject of electricity?

Ans. We had.

Int. 13. Did you then introduce Mr. Church or Mr. Sawyer to Mr. Man?

Ans. I made an appointment with Mr. Church to go with me that evening to go to Mr. Man's house in Brooklyn?

Int. 14. Did you keep the appointment?

Ans. Mr. Church called at my house that evening and I went with him to Mr. Man's house, and gave him an introduction. Mr. Sawyer was not with me at that time.

Int. 15. Did you subsequently introduce Mr. Sawyer to Mr. Man?

Ans. I did, the next evening.

Int 16. Were you present at the interview with Mr. Sawyer and Mr. Man that evening?

Ans. I was, and also Mr. Church.

Int. 17. What was the general subject of conversation between yourself and Mr. Sawyer and Mr. Man on that occasion?

Ans. The principal subject was electricity, and to devise a plan to get capital in to develop Mr. Sawyer's inventions.

Int. 18. Inventions appertaining to electric lighting?

Ans. Yes.

Int. 19. Did that interview result in an arrangement between Mr. Sawyer and Mr. Man to undertake the development of electric lighting?

1786 Ans. It did. There was an appointment made that they should meet the fore part of the week, I think Tuesday, and consider the subject-matter.

Int. 20. State, if you know, what steps they took towards the making of electric lamps.

Ans. Of my personal knowledge, I don't know as I can say anything more than Mr. Sawyer informed me that Mr. Man had agreed to furnish some capital to make some experiments in electric lighting.

Int. 21. Did you subsequently see any electric lamps made by Sawyer and Man?

Ans. I did.

Int. 28. Where and when did you see them?

Ans. I don't know as I can state the time exactly. Some days after I was invited to go up to Centre street.

Int. 23. Do you recollect the number in Centre street?

Ans. No, sir.

Int. 24. Did you go there with Mr. Sawyer or Mr. Man?

Ans. I went up with Mr. Church.

Int. 25. Who did you see there, and what did you see there in the way of any electric lamp?

Ans. I saw Mr. Sawyer and Mr. Man and an old gentleman who seemed to be a mechanic, who was said to be Mr. Sawyer's father.

I saw an electric lamp there. I don't know that I can describe the form of it now.

Int. 26. Did you see more than one?

Ans. I cannot say at that time whether I saw more than one or not.

Int. 27. Did you subsequently see any of the Sawyer-Man lamps at that place?

Ans. I cannot say that I did. It was a very short time after that I saw the Sawyer-Man lamps, but whether it was at that place or at Howard street I am not certain.

1787 Int. 28. What, if anything, did Mr. Man or Mr. Sawyer say to you about carbons to be used as illuminating conductors for those lamps either at that time or at any time subsequently?

Ans. Mr. Man stated to me that, I think, they had sent to France to get some carbons, and that they had not proved very satisfactory—Paris, I think. Some little time subsequent to this conversation I was coming down in the cars; at Franklin street Mr. Man stepped onto the car and showed me some carbons—paper carbons—that he said he had made himself.

Int. 29. How many were there?

Ans. I couldn't say; he had quite a number of them—different shapes, in an envelope.

Int. 30. Did he state where he had made those carbons?

Ans. He did; he said he made them at home.

Int. 31. Did he say he had carbonized them himself?

Ans. He did.

Int. 32. How did he say he had carbonized them?

Ans. I don't think I can tell. He said he had carbonized them in his laboratory.

Int. 33. Did he say in what fire or furnace he had carbonized them?

Objected to as leading and suggestive to the witness.

Ans. He said he had carbonized them in his little cupola furnace. I forgot it exactly. I have been in his little place there where he worked.

Int. 34. What was the shape of the carbons he showed you?

A. There were some circles—half circles—some straight. I don't recollect now all the shapes.

Int. 35. Did you take them in your hands and look at them?

Ans. I couldn't say whether I took them in my hands or not. I saw them when he took them out of the envelope.

1788 Int. 36. When was this that he showed you these carbons?

Ans. I cannot state definitely the time. It was several weeks after they commenced working at this business.

Int. 37. Can you state what year it was?

Ans. In 1878. I think March or April. It was early in the spring.

Int. 38. Did you subsequently see any carbons like those you have mentioned in the Sawyer-Man lamps, and if so, please to state where?

Ans. I did. I noticed the half-circle carbon particularly when that was on exhibition. I think that was on Howard street. I am not positive, but I think it was.

Int. 39. Are you clear that it was in Howard or Centre street?

Ans. It was after they left Centre street, I think.

Int. 40. Who took you to see them on that occasion, or did you go by yourself?

Ans. Mr. Church gave me notice that they would make an exhibition in the afternoon of the morning he came to see me, and I went up.

Int. 41. Was Mr. Sawyer or Mr. Man there or both of them?

Ans. They were both of them there.

Int. 42. In how many lamps did you see these half-circular carbons?

Ans. I cannot say how many. They exhibited several lights at the same time. They had several lights strung around the room, I don't know how many of them had circular carbons.

Int. 43. Was there more than one that had circular carbons?

A. I can't say positively. There were several lights around. I didn't notice particularly whether they were all circular carbons or not.

Int. 44. What did Sawyer or Man say to you about these carbons at that time, if anything?

1789 Ans. Not to me directly. There were several gentlemen there; they explained the carbons and they were all listening at the same time.

Int. 45. Did you hear them say what the carbons were made of, and if so, please state.

Ans. I don't know as there was anything particular said at that time any more than that they were said to be paper carbons the same as Mr. Man showed me some time previous.

Int. 46. Were you interested in any way in the Electro-Dynamic Light Co. at that time?

Ans. Only as a broker in introducing parties. I was a stockholder.

Int. 47. Were other stockholders of the Electro-Dynamic Light Co. present at that time?

Ans. I think there were several of them.

Int. 48. Did you subsequently see these lights at any other place; if so, please state where.

Ans. I saw subsequently, at this same place, and I think I saw them when they were moved to Walker and Elm streets.

Cross-examination by Mr. GRIFFIN:

X Int. 49. At the close of your last answer you asked whether the Walker and Elm street place was where Hochhausen was, did you not?

Ans. Yes; I wasn't clear whether they were on the corner of Walker and Elm or on Howard street.

X Int. 50. How was it that you were not clear on this point?

Ans. I was frequently at their place of business at both places and I couldn't call to mind now whether they were at Howard or on the corner of Walker and Elm.

X Int. 51. Do you mean to say you are not certain whether Hochhausen was at Howard street or at Walker and Elm?

1790 Ans. No, I meant to be understood that when this exhibition was made I was not certain whether it was on Howard street where Hochhausen was or whether it was the corner of Elm and Howard.

X Int. 52. Can you describe the lamp which you saw at Centre street when you went there with Mr. Church?

Ans. I don't think I can describe the lamp at all; they had so many different forms of lamps there to experiment on.

X Int. 53. I mean the lamp that you first saw at Centre street. Can you describe that?

Ans. No, I don't know that I can. I don't recollect exactly what the lamp was.

X Int. 54. Are you certain that you ever saw that same lamp again?

Ans. I saw an exhibit of all the different lamps that they had made several months after they commenced operations, commencing at No. 1. I couldn't see how many lamps there were. There were several of them that they had been experimenting with.

X Int. 55. Are you certain that you ever saw the Centre-street lamp again?

Ans. I am.

X Int. 56. Where did you see it?

Ans. I saw it in their shop after they moved to the corner of Elm and Howard. That is the time I saw the several lamps they were experimenting with.

X Int. 57. Are you sure it was the same lamp?

Ans. Yes, sir; I should think it was the same lamp.

X Int. 58. Can you describe it?

Ans. I cannot describe it.

X Int. 59. When did Mr. Man state to you that he had sent to France to get carbons?

Ans. A short time after they commenced operations at Centre street.

X Int. 60. What kind of carbons had to be sent for?

1791 Ans. He said they had sent for French carbon, that is all I know about it. I don't know what kind he sent for.

X Int. 61. Do you know whether they used any French carbons?

Ans. I do not.

X Int. 62. Did you ever have any lamps called to your attention which were said to have French carbons in them?

Ans. Not to my recollection.

X Int. 63. You never heard of them so far as you remember?

Ans. I do not recollect of hearing of their using them.

X Int. 64. When did you see Mr. Man's cupola furnace?

Ans. I couldn't tell when. I have seen it a number of times when I have been in his little shop that he worked in.

X Int. 65. Where was that shop?

Ans. In his house, 118 Putnam avenue, Brooklyn.

X Int. 66. Did Mr. Man tell you he had carbonized what he showed you in his cupola furnace?

Ans. I don't know that he mentioned the furnace. He said he had carbonized the samples he showed me.

X Int. 67. He didn't tell you how he had carbonized them?

Ans. I think he did, but I don't recollect now what the process was.

X Int. 68. Did he tell you the material of the carbons?

Ans. He explained it all very particularly at the time, but I don't recollect—he called them paper carbons.

X Int. 69. That is about all you remember?

Ans. That is about all I remember about the carbons.

X Int. 70. When Mr. Church took you to the exhibition which you think was in Howard street, who were there to your knowledge?

Ans. Mr. Man, the two Sawyers, Wm. E. and his father, Mr. Myers—I don't recollect his given name. Mr. Church was there and several others whose names I do not now recall to mind.

1792 X Int. 71. Were they members of the Electro-Dynamic Co.?

Ans. That was my understanding at the time—that they were members of the company who came up to see the exhibition.

X Int. 72. Are you positive that at that exhibition there was more than one lamp with a circular carbon?

Ans. There were several lamps there on exhibition. I suppose they were all with circular carbons.

X Int. 73. What makes you suppose that?

Ans. I was examining the light and I remarked to Mr. Man—I asked him whether that was his paper carbon. That was the question I put to him. I supposed the lights were all similar. I didn't examine particularly but the one.

X Int. 74. And you have no recollection of any other shapes?

Ans. I have no recollection of seeing any other shapes that day—any other form of carbon.

X Int. 75. Have you any recollection of seeing any other shapes any other day at Howard street?

Ans. Previous to this exhibition I saw them using the wood carbon they called it. That was a straight carbon.

X Int. 76. Was that the only time you remember seeing a straight carbon?

Ans. I don't recollect of seeing any straight carbons after this exhibition, though I may have done it.

X Int. 77. You can't say whether you did or not?

Ans. Not of their production.

X Int. 78. What do you mean by that?

Ans. I have no recollection of seeing any straight carbons used by them after that.

X Int. 79. Who first spoke to you as to testifying in this suit?

Ans. Mr. Man.

X Int. 80. How many conversations did you have with him?

1793 Ans. Never had any extended conversation. He said he might have to call on me to establish the time that Mr. Sawyer was introduced to him.

X Int. 81. Did he talk to you about the paper carbons?

Ans. Yes, he asked me what my recollection was in the matter of paper carbon.

X Int. 82. Did he talk over what had occurred?

Ans. No, sir.

X Int. 83. Whom besides Mr. Man have you seen as to your testimony?

Ans. I have not seen any one except the gentleman to whom I gave my recollections as to the introduction—Mr. Kerr, I believe.

X Int. 84. Did he talk to you about paper carbons?

Ans. No, sir.

EDWIN L. HAYES.

1794 *Deposition of David Hennessy.*

David Hennessy being called on behalf of complainant and duly sworn testifies as follows:

Int. 1. What is your name, age, residence and occupation?

Ans. David Hennessy, 57 years of age, I reside 205 West 48th street, New York city. I am a plumber.

Int. 2. Are you acquainted with Albon Man, and if so, how long have you known him?

Ans. I am. I have known him twenty years, or thereabouts.

Int. 3. Did you do any plumbing work for Mr. Man at 94 Walker street?

A. I don't know the number, but I did at the corner of Elm and Walker streets, if that was the number.

Int. 4. Do you recollect when you did that work?

Ans. I done it October, 1878, or thereabouts, I think.

Int. 5. Have you a memorandum of the work you did for him at that time? If you have please produce it?

A. I have, and I produce it.

Int. 6. From what did you make this memorandum, and when?

Ans. From my books, I made it recently.

Int. 7. Do you mean within a week or ten days?

Ans. Yes, sir.

Int. 8. Does this memorandum represent when the work was done; the dates?

Ans. Yes, sir.

Int. 9. Have you visited the premises lately?

Ans. Yes, sir.

Int. 10. Within a week or ten days?

Ans. Yes, about ten days.

Int. 11. Do you remember a light hole in the northwest corner of the building?

Ans. Yes, sir.

Int. 12. Did you put any of this work in that light hole, and if so, what?

1795 Ans. Yes, sir, I put three pipes there.

Int. 13. What part of this work was at the top next to the roof of the building there?

Ans. A large air chamber.

Int. 14. What parts ran down from that air chamber?

Ans. There was an exhaust went down to the basement; something I didn't understand.

Int. 15. Under whose direction did you put that work up?

Ans. Mr. Albon Man.

Int. 16. At the time you put it up did he tell you what it was for?

Ans. No, sir.

Int. 17. All that you know of it, as I understand, is that you put it up under his directions?

Ans. Yes, sir.

Int. 18. Did any of the pipes lead into the shop?

Ans. Yes, that small tube pipe led into the shop and also downstairs.

Int. 19. State, if you know, what was at the end of the pipe that led into the shop.

Ans. Two small little air cocks on it.

Int. 20. Was there a pipe led from the top down to the basement or street?

Ans. Yes. It led down to the basement.

Int. 21. Were any of these pipes supplied with water connected to the Croton water?

Ans. Yes, sir.

Int. 22. What did the Croton water pipe lead into?

Ans. It led into this vessel upstairs, this chamber up under the roof.

Int. 23. Does this memorandum which you have produced—a copy from your books—contain a true copy of items for the work done there by you?

Ans. Yes, sir.

Memorandum offered in evidence and marked Complainant's Exhibit Hennessy Memorandum, April 5, 1889.

(Signed) DAVID HENNESSY.

1796 COMPLAINANT'S EXHIBIT HENNESSY MEMORANDUM. April 5, 1889. W. T. F., S. E.

NEW YORK, *October*, 1878.

Mr. Albon Man to David Henessy, Dr., practical plumber and gas-fitter, 1597 Broadway, bet. 48th and 49th Sts.

Oct. 17.	To	115 lbs. lead pipe.
	"	40 ft. ¼ lead tubing.
	"	2⅝ stops and wastes finished.
	"	37 ft. ½-inch gas pipe.
	"	1½-inch soldering nipple.
	"	5 prs. tacks and screws.
	"	18 pipe hooks.
Oct. 18.	"	7 lbs. 2-inch lead.
	"	4 ft. ⅛-inch gas pipe.
	"	2 brass ¼-inch gas cocks.
	"	cartage, charcoal, candles and screws.
	"	1½ day plumber and assistant.
	"	8 lbs. solder.
Oct. 19.	"	2½ ft. ⅛ gas pipe.
	"	1 ft. ⅛ elbow.
	"	1 ft. ⅛ tee.
	"	2 ft. ⅛ nipples.
	"	1 ft. ⅛ coupling.
	"	1 ft. ⅛ air cock.
	"	2 ft. ½ unions.
Oct. 29.	"	73 ft. ⅜ gas pipe.
	"	1 day gas-fitter and assistant.
Oct. 30.	"	17 ft. ⅜ gas pipe.
	"	18 fittings.
	"	12 straps.
	"	2 ft. ½-inch lead pipe.
	"	2 lbs. solder.
	"	2⅜ stop-cocks.
	"	1 large bracket.
	"	3 small brackets.
	"	coal, candles and screws.
	"	¼ day plumber and assistant.

1797 *Deposition of Edward Rowe.*

EDWARD ROWE being called on behalf of complainant and duly sworn testifies as follows:

Int. 1. What is your name, age, residence and occupation?

Ans. Edward Rowe, 74 years of age, I reside in the city of Brooklyn on the corner of Franklin and Fulton avenues, I am United States assistant appraiser at the New York custom-house.

Int. 2. Are you acquainted with Albon Man?

Ans. I am, sir.

Int. 3. Were you acquainted with him in 1878?

Ans. Yes, I have been acquainted with him over twenty years. I have lived a neighbor to him in Brooklyn during all that time. I have been a member of the board of education of Brooklyn for the past twenty-five years.

Int. 4. Please to state generally what information you have regarding an electric lamp or light from Mr. Albon Man?

Ans. Coming in the car with me one morning we were talking on the subject of electricity, and he asked me if I would like to see anything of that kind, and accepting his invitation he took me to a building that seemed to be devoted to mechanical purposes and I accompanied him to this place, and he found he was not able to show me what he wanted on account of the workmen not being there, and invited me to come some other time. Shortly after, I accompanied him to the same place and he then showed and explained to me this new invention, electric light produced I believe by what he called an incandescent burner which they were then to work on. After satisfying my curiosity and explanations I left and went to my business.

Int. 5. What, if anything, did Mr. Man say to you while you were there about the incandescing carbons? Did he tell you what they were made of?

1798 Ans. Yes, he told me—he showed them to me—he said they were made of paper and I expressed my surprise that they didn't burn up.

Int. 6. When was this?

Ans. In the early part of 1878.

Int. 7. How many lamps did you see there—incandescing lamps?

Ans. He showed me a number. How many I can't say.

Int. 8. How long were you there on that occasion?

Ans. I suppose from half to three-quarters of an hour, explaining to me things.

Int. 9. Have you any knowledge of the subject except as explained to you by Mr. Man?

Ans. No, sir, and no mechanical genius. It is all Greek to me.

Int. 10. How do you fix the date?

Ans. Because my business then was on Grand street near Broadway, New York, and I moved from that location that year.

(Signed) EDWARD ROWE.

Adjourned till Saturday, the 6th inst., at 11 a. m.

1799 NEW YORK, *April 9th*, 1889—11 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

Testimony of George S. Beith.

GEORGE S. BEITH, a witness on the part of the complainant, being duly sworn, testifies as follows in answer to interrogatories by Mr. KERR:

Int. 1. State your name, age, residence and occupation.

Ans. My name is George S. Beith, my age is 50 years, residence New York city; I am a machinist and engineer.

Int. 2. Where are you now employed?

Ans. At the New York Lumber and Wood Working Co., at 134 Alexander avenue, New York.

Int. 3. When did you enter the employment of that company?

Ans. On the 9th of April, 1883.

Int. 4. Have you continued in its employment ever since?

Ans. Yes, sir.

Int. 5. Please state whether that company has a Sawyer-Man electric lighting plant, and if so, when it purchased the same?

Ans. It has such a plant. It was put in by the Consolidated Electric Light Co., in November, 1883.

Int. 7. What was the size of that plant?

Ans. It was 250 lights.

Int. 8. Has it since been increased?

Ans. Yes, sir. It is now 400.

Int. 9. Has that plant been in use ever since November, 1883?

Ans. We have used it every winter until the winter of '87 and
'88, when it was not in use. This past winter it has been in
1800 use. During the winter of '87 and '88 they removed the
business to Batavia, so they had no need of the lights.

Int. 10. Can you produce one of the lamps which was in use in November of 1883?

Ans. Yes, sir, this is one.

Witness produces a lamp which is offered in evidence as Complainant's Exhibit New York Lumber Co. Lamp, W. T. F., examiner.

Int. 11. Please state how those lamps burned.

Ans. The lamps gave satisfaction, seemingly, there were no complaints.

Int. 12. How long was that particular form of lamp used by the lumber company?

Ans. They were used that winter, '83 and '84, all winter.

Int. 13. What was their guaranteed life?

Ans. Twelve hundred hours.

Int. 14. What was their candle power?

Ans. Sixteen candle power.

Int. 15. What was their percentage of loss during that winter?

Ans. Out of the number of lamps which we got when the plant was first put in, there was about 10 per cent. loss.

Int. 16. What period of time was covered by this 10 per cent. less?

Ans. Our rate of ten per cent. was for that winter, from about November to about April.

Int. 17. You have spoken of the use of the lamps in the winters, weren't they used in the summers, and if not, why not?

Ans. We have used them in the summer, but it was on a rare occasion, during a thunder storm when it got dark for fifteen or twenty minutes. Other than that there was no occasion to use them.

Int. 18. How did those lamps used in the fall and winter
1801 of '83 compare with the lamps which you now use?

Ans. Well, perhaps the percentage of loss might be a little greater during that fall. The lamps that we then used would get a little more smoky than they do now, and we would take them out and replace them with others. I might also state that those which were kept there were brilliant and gave good light.

Int. 19. Does the lamp which you have produced show the smokiness you have spoken of?

Ans. Yes, sir, a little of it.

Int. 20. Do you know whether this lamp you have produced is still in working order?

Ans. I tried that last night; it was. You can't see that smoke when it is lit, as much as you do now.

Int. 21. Where has that lamp been since '83?

Ans. It has been in the factory of the wood-working company, in my charge.

Int. 22. Do you know how long it was in use?

Ans. Only that winter of '83 and '84.

Cross-examination:

X Int. 23. What were the working hours of the lumber Co.?

Ans. Ten hours a day. They commenced at seven o'clock in the morning, and stopped at half past five.

X Int. 24. How were the rooms of the lumber company lit during the daytime?

Ans. In clear weather they were lit by daylight. In very dark weather some of the rooms had to be lit by electricity.

X Int. 25. What was the hour for lighting up?

Ans. Ten minutes to seven in the morning for starting till about about half past eight and sometimes nine; from half past four in the afternoon until a quarter to six.

X Int. 26. What personal knowledge have you as to whether the lights were lit at that time each day?

1802 Ans. They were not all lit at the same time.

X Int. 27. What is the greatest number of lamps you know to have been lit during ordinary working hours?

Ans. We had eighty on one floor.

X Int. 28. In what part of the works was your position while on duty?

Ans. At the engine, boilers, dynamo and lamps—the plant right through.

X Int. 29. When you gave the hours of lighting up, do you mean that was the time when the dynamo was set in operation?

Ans. Yes, sir.

X Int. 30. And during the hours the dynamo was running, such of the lamps were lit as were necessary, according to circumstances?

Ans. Yes, sir; that's right.

X Int. 31. And that number would vary according to the weather and other things, would it not?

Ans. The weather was the principal cause of any variance in the time of lighting or the use of the lamps.

X Int. 32. It depended altogether upon how dark it happened to be?

Ans. Yes, sir, exactly.

X Int. 33. You produced a lamp this morning; after those lamps were changed, what was the shape of the globes used?

Ans. Pear-shaped.

X Int. 34. When were these pear-shaped lamps put in?

Ans. I can't say positively whether we had any of those that winter; I think we had them the following winter.

X Int. 35. That was the second winter of use, was it not?

Ans. Yes, sir, the second winter, '85 and '86.

1803 X Int. 36. Did you ever test the lamps to ascertain their exact candle power, or when you stated their candle power in your direct examination, did you simply mean that they were bought as sixteen-candle lamps?

Ans. Exactly. I had no means of testing them.

GEO. S. BEITH.

Adjourned to April 10th, 1889, at 11 a. m.

NEW YORK, *April 10th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin of counsel for defendant.

Counsel for complainant offers in evidence the paper book shown to the witness Thomas A. Edison at questions 516 and 517 of his examination in this case, and marked by the examiner for identification at that time as Complainant's Exhibit Edison, Swan and Maxim Record, the same containing the deposition of said Thomas A. Edison in said interference case on pages 1 to 13 inclusive, and 154 to 262 inclusive, and the same is marked "Complainant's Exhibit Edison, Maxim and Swan Interference Record, testimony on behalf of Edison, W. T. F., examiner, April 10, 1889."

Objected to as incompetent, immaterial and irrelevant.

Complainant's counsel also offers in evidence a certified copy of the file-wrapper and contents in the matter of the application of Thomas A. Edison, filed December 11, 1879, serial No. 146–30, for improvements in electric lamps and method of making the same.

1804 Said copy being certified by Benton J. Hall, Commissioner of Patents, on March 28th, 1889, as shown by the certificate thereto annexed, and the same is marked "Complainant's

Exhibit Edison File-wrapper and Contents, W. T. F., examiner, April 10, 1889."

Complainant's counsel also offers in evidence a certified copy from the records of the Patent Office of a letter from Dyer & Wilber, attorneys for Edison, dated October 4th, 1880, ordering copy of file-wrapper, contents and drawing of the application of Sawyer and Man, filed January 9th, 1880, for improvement in electric lights, and a certificate of the furnishing of said copy on October 16, 1880, the said copy being certified by C. E. Mitchell, Commissioner of Patents, on April 2d, 1889, and the same is marked "Complainant's Exhibit Certified Copy of Dyer & Wilber Letter of October 4th, 1880, W. T. F., examiner, April 10, 1889."

Objected to as incompetent, immaterial and irrelevant.

Testimony of Hugh R. Garden.

Hugh R. Garden, a witness on the part of the complainant, being duly called and sworn, testifies as follows in answer to interrogatories propounded to him by Thomas B. Kerr:

1 Q. State your name, age, residence and occupation, and what connection you have, if any, with the complainant company.

A. Hugh R. Garden, 48, New York city, lawyer and president of the complainant company.

2 Q. How long have you been connected with the complainant company, and in what capacities?

A. I have been connected with the complainant company since its organization in September, 1882, and was vice-president of the company from the date of its organization until some time early in
the spring of 1885 when I was president of the company for
1805 a few weeks, I was thereafter vice-president of the company
until the autumn of 1888, when I became president of the
company, and have continued as president of the company until the present time.

3 Q. What connection have you had ever since the organization of the company with its active business management?

A. From the date of its organization until the spring of 1885 I was compelled, much against my inclination and education, to take an active part in its business management.

4 Q. What familiarity have you acquired with the manufacture of incandescent electric lamps?

A. Very soon after the organization of the company I found that as the official head of the legal department, it was necessary for me to familiarize myself with the methods and processes of manufacture of the incandescent electric lamp, and for many months I made it my business to spend a few hours almost every day at the manufactory of the company studying the details of such manufacture, and I thus became familiar with the manufacture of incandescent electric lamps.

5 Q. Are you acquainted with Henry E. Vineing, and if so, how did you make his acquaintance?

A. I know a man named Vineing, his Christian name I am not familiar with. The man I refer to was employed in the manufactory of the complainant company, my recollection being that he was an Englishman who came to us recommended by some people connected with the Lane Fox Company, who were manufacturers of incandescent lamps in England, and he was employed by our superintendent, because he stated that he could make an incandescent electric lamp better than anybody else.

6 Q. What was your experience with him in regard to his ability to make incandescent electric lamps?

A. Very unsatisfactory. He was an ingenious mechanic but was evidently not familiar with the methods and processes 1806 used by the manufacturers of incandescent electric lamps, and devoted most of his time to unnecessary and useless experiments which he claimed at the time would be beneficial, but which proved to be absolutely injurious to the lamps then being manufactured by the company.

7 Q. Had the company prior to that time been manufacturing and selling incandescent electric lamps?

A. It had, but its resources being limited, its manufacturing facilities were not very extensive. I recall now amongst the places where its lamps were in use by purchasers the building at the corner of Wall street and Broadway in the city of New York, owned jointly by the First National bank and the National Bank of the Republic, and called the United Bank building; also an establishment on Union square in New York, owned and occupied, I think, by William H. Jackson & Co.; also a manufacturing establishment in Harlem, styled, I think, the New York Wood-Turning Company, and at that time the company was under contract — the incandescent plant for the new Mutual Life building then being erected in the city of New York, the contract calling, I think, for some 1,600 lights.

8 Q. What satisfaction did the lamps give, which you were making prior to Vineing's employment by the company?

A. I never heard of any unusual complaints about the quality or life of the lamps, and the purchasers always paid their bills for lamps promptly.

9 Q. How long did Vineing continue in the employment of the company, and what was the cause of his leaving?

A. I do not remember how long he was in the employment of the company. He was discharged at a time when the force was being reduced, he being one of those who could best be spared, as ranked among the least efficient.

10 Q. Vineing again obtained employment from the company. 1807 Can you state the circumstances of his re-employment and the termination of that re-employment?

A. As I stated, Vineing was an ingenious mechanic and I think in the summer of 1885, Mr. Henry C. Davis being then the manager of the commercial affairs of the company, Vineing was employed by him, I believe, directly to assist in fitting up the factory for an increased output. During that period also much of his time was occupied in carbonizing and in subjecting to the hydrocarbon process invented by Sawyer and Man of many kinds of fibrous material, including paper, bamboo, various kinds of woods, split to size, grasses, jute, manilla, threads of various kinds woven and twisted. This was done during a period of several weeks, perhaps months, under orders from the office of the legal department, for the use of the experts and the lawyers for the complainant to enable them to decide by comparison with the carbons manufactured by the Edison Electric Light Co. which had been stipulated into a case then and now pending in the circuit court of the United States for the southern district of New York between the complainant corporation and the Edison Electric Light Co. whether or not a stipulation on the part of the Edison Company that the carbons manufactured by them were not subjected to the hydrocarbon treatment, was true. The result of the experiments and tests made of the carbons manufactured in various ways and of various materials above referred to, satisfied the experts and the counsel of the complainant company that the carbons of the defendant company were subjected to more or less of such treatment, and thereupon witnesses were summoned by the complainant from the factory of the Edison Company, who proved it.

11 Q. Were these experiments, the carbonization of various materials mentioned by you, which were done by Vineing, designed for the production of filaments for use in commercial lamps to be manufactured by the complainant?

A. No; but at the same time that these series of experi-
1808 ments upon various materials, as above referred to, were
being made, the company was manufacturing its usual
standard lamp.

12 Q. During the time of Vineing's first employment did he carbonize any other materials than those the company was using in the manufacture of its commercial lamps, and if so, under what circumstances?

A. Prior to the employment of Vineing the company had been using for the most part, carbonized bamboo filaments in its lamps. Vineing insisted that he knew of valuable material used by Lane-Fox, and of other material discovered by himself, which with improved methods of manufacture to be explained by himself, would produce a better carbon than we were then using. It very soon developed, however, that he was merely experimenting and that the use of those materials or those methods of manufacture did not produce a better carbon or a better lamp, but in reality seriously interfered with the uniformity of the manufactured product, which uniformity is one of the essentials in successful incandescent electric lighting. His persistence in continuing these experiments, and not abiding by results already obtained by the company, was the chief reason for his discharge.

13 Q. Under what circumstances did Vineing's second employment with the company terminate?

A. The company had leased a new factory in Brooklyn for the enlargement of its works and Mr. John M. Robertson, the superintendent, reported that he could get no satisfactory work out of Mr.

Vineing in the mechanical department in which he was employed, and asked that he be discharged. Mr. Vineing was given the opportunity "to resign," and he "resigned."

15 Q. Please give the title of the suit on the treating patent to which you have referred to.

A. U. S. circuit court, southern district of New York, between The
Consolidated Electric Light Company complainant, and The
1809 Edison Electric Light Company, defendant. In equity on
bill, etc., G, 3406. On patent 211,262.

15 Q. Please state what the attitude of the Edison Electric Light Company towards the Consolidated Electric Light Company has been ever since the date of the organization of the latter.

A. The attitude of the Edison Company toward the Consolidated Electric Light Company has been one of continuous and extreme hostility, and all the resources that apparently unlimited means, great power and wide-spread reputation could exert, were used to break down the organization and prevent its commercial success. Every effort was made to intimidate would-be purchasers from the Consolidated Electric Light Company by threats of suits to be brought for infringement, and through the press and by private circulars, the commercial world was constantly urged to remember that the Edison Company would not permit any other company to enter a field which they alleged belonged to the Edison Company exclusively. During this period an interference was pending in the United States Patent Office between the Edison Company and the Consolidated Electric Light Company, the successor of the Electro-Dynamic Light Company, which resulted, after a contest of about five years in the success of the Consolidated Electric Light Company, and the issue of a patent to it on the 12th of May, 1885, the same being the patent in suit. The Consolidated Electric Light Company for its own protection and the protection of its purchasers, was compelled to bring several suits upon patents granted to Sawyer and Man and owned by it, against the Edison Electric Light Company, and in addition to an enormous amount of money expended in endeavoring to overcome the commercial strength and financial power of its antagonist, it has been compelled to expend more than $100,000 in these legal controversies. At the outset, the Consolidated Electric Light Company was poor financially, but had confidence in its pat-
ents and in its ability to attain commercial success. This
1810 confidence is now shared with it by the vast number of con-
sumers who are now using the Sawyer-Man incandescent
electric lamps.

16 Q. Please state what the attitude of the other electric lighting companies engaged in incandescent lighting, toward the complainant company, is.

A. The only companies in this country other than the complainant company who are largely engaged in the manufacture and sale of incandescent electric lamps, are the defendant company, the Westinghouse Electric Co., the United States Electric Lighting Co., and the Thomson-Houston Electric Co. All of these companies, with the exception of the defendant company, are manufacturing and selling incandescent electric lamps under contracts of license with the Consolidated Electric Light Co., and a large number of lamps manufactured by these companies under the Sawyer-Man patents are being sold to local plants and stations originally erected by the Edison Electric Light Co.

Direct examination closed.

Adjourned to April 11th, 1889, at 11 a. m.

NEW YORK, *April* 11*th*, 1889.

17 X Q. Was not a suit in equity brought against your company by the Edison Electric Light Co., May 2nd, 1885, upon the Edison bamboo filament patent?

A. A suit was brought by the Edison Company against the Consolidated Electric Light Co., upon the bamboo filament patent, the date of which suit I do not remember. I only remember that it was brought some time after several suits had been instituted by the Consolidated Electric Light Co. against the Edison Electric Light Co. for infringement of several of the Sawyer-Man patents.

1811 18 X Q. Can you not ascertain from your papers whether the date of beginning that suit was not as I stated?

A. I find that I have sent all my papers in that case over to Mr. Broadnax.

It is stipulated that the suit on the Edison bamboo filament patent was commenced May 2d, 1885, the bill being sworn to as of that date.

19 X Q. In addition to the concerns mentioned in your seventh answer, who else, if anybody, was employing your lamps?

A. I do not think the company was prepared to sell dynamos and install electric lighting plants prior to the summer or early in the fall of 1883, and they therefore did not have many such plants in operation. Those referred to in answer seven are impressed upon my mind because they were in New York. I do not recall any others at this moment.

20 X Q. Are not the concerns mentioned in your seventh answer substantially all the concerns who at that time were using your lamps?

A. I do not think they were, cannot say positively but am sure there were not many others.

21 X Q. The lamps sold to all these concerns had bamboo carbons, had they not?

A. A large majority were bamboo carbons.

22 X Q. What other materials do you know them to have used in those lamps sold to any of the concerns you have mentioned?

A. Thread and grass of some kind, the name of which I have forgotten.

23 X Q. Subsequently did you not adopt bamboo for the filament in all your commercial lamps?

A. In the lamps manufactured at the factory of the Consolidated Electric Light Co. we did.

24 X Q. That was the only factory over which your company had control, was it not?

1812 A. Up to the spring of 1885, yes. After that period companies not controlled by us manufactured lamps under license from us for which they paid us a royalty. From August 23rd, 1887, to October 1st, 1888, the Consolidated Electric Light Co. operated a factory at Pittsburgh, making many thousand lamps *per diem*, in which the carbonized filament used was made of silk thread.

25 X Q. During the year 1885 what material did you understand was used by the Edison Company in its lamps?

Objected to as immaterial.

A. The stipulation in the suit referred to by me in my examination-in-chief made by the Edison Company recited that their carbon filaments were made of bamboo, and such was the general opinion.

26 X Q. In any of the Edison lamps which you or the experts examined during the year 1885, did you find the material to be anything else than bamboo?

A. They were certainly all made of fibrous material and I don't remember seeing any that were not of bamboo.

27 X Q. Is not the means of telling whether a carbon has been treated or not, an optical examination either by the eye or by the microscope?

A. It is the only means I know of.

28 X Q. Were not the various materials carbonized by Vineing tried in lamps at your works?

A. Some of them were and some were not.

29 X Q. Do you know any of the classes of material which he carbonized which were not actually tried in lamps? I do not refer to single specimens, but to classes of material.

A. It may be possible that Vineing attempted to make lamps, or rather incandescent conductors for lamps, out of every class of material that he carbonized. My objection to Vineing's course at the factory was that he spent his time in useless experiments, instead of using the material which we had theretofore found to be good, bamboo, for instance, and using such as an incandescent conductor.

1813 30 X Q. In your 16th answer you mentioned several electric light companies, with the exception of the Edison Company are not all those companies either owned or commercially controlled by contract or lease by the Westinghouse Electric Co.

A. I do not know the relations between the United States Company, and the Westinghouse Company: the Thomson-Houston Company is not under contract of lease or, as far as I am aware, any other contract relating to lamps with the Westinghouse Company. The commercial assets of the Consolidated Company were leased by the Westinghouse Electric Company, on the 1st day of October, 1888, and the lamp factories of the Consolidated Company are now being operated by the Westinghouse Company.

31 X Q. How long under a microscope does it take you or an expert to tell whether a carbon has been treated or not?

A. The time taken for examination would depend upon the amount of the treatment; a very slight or delicate treatment requiring a more careful investigation, than one where the filament is heavily coated by the treatment.

32 X Q. If I gave you a filament to ascertain whether it had been treated, all that would require to be done would be to pass that filament throughout its entire length under the microscope and attentively note the appearance, is that not so?

A. No, that is not all; I have seen cases in which filaments had to be examined with the rays of light falling upon the filament at different angles and with different degrees of intensity before it could be determined whether or not they were treated.

33 X Q. In other words you had to use the proper light for the illumination of opaque objects under the microscope, was that not so?

1814 A. Yes, you had to obtain the proper light and a proper microscope.

34 X Q. And that is all there is to it?

A. Not being an expert I cannot say, but that's all I know about it.

HUGH R. GARDEN.

NEW YORK, *April* 11, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and Mr. Griffin for defendant.

Testimony of Edward R. Knowles.

EDWARD R. KNOWLES, being called on behalf of complainant, and duly sworn, testifies as follows:

1 Q. What is your name, age, residence and occupation?

A. Edward R. Knowles, 37 years of age. I reside at 439 A, Waverly avenue, Brooklyn. I am an electrical engineer.

2 Q. State whether or not you are the same Edward R. Knowles that testified in the interference between Wm. E. Sawyer and Albon Man on one side and Thomas A. Edison on the other, on or about the 23d day of November, 1882.

A. I am.

3 Q. I place in your hands a book containing a certified copy of your deposition in that case, the same being a part of the printed record of the testimony in that interference. Please to look at the book and state on what pages it begins and terminates.

A. It begins on the 84th page and terminates on the 92d.

1815 4 Q. How recently have you read this deposition?

A. Yesterday.

5 Q. Assuming the questions of that deposition to be propounded to you now, would you make the same answers to them?

A. I should, or substantially the same.

6 Q. Are the answers to those questions true, as you now recollect the facts inquired about?

A. They are to the best of my recollection.

7 Q. Where are you now employed?

A. By the Mutual Electric Manufacturing Company.

8 Q. How long since you left the employ of the Consolidated Electric Light Company?

A. I left them on the 12th of February, 1884.

The deposition of the witness in the interference in now offered in evidence under the stipulation between counsel as to such depositions already of record, and the examiner is requested to write said deposition into this record as a part of the same, and the same is as follows: (it being stipulated between counsel that the examiner may compare the same with a certified copy of said deposition and certify the same as correct.)

COUNSEL'S NOTE.—The deposition of Edward R. Knowles in the interference case above referred to, is printed in volume 3 of this record, on pages 622 to 630 inclusive.

Cross-examination by Mr. GRIFFIN:

9 X Q. In your answer to question 43 on interference, you state that you used the carbons there mentioned in the lamp known as the Sawyer and Man lamp. Can you describe that lamp generally, if so, do so?

1816 A. I can. The lamp consisted of a long glass tube cemented into a metallic cup, this forming one part of the lamp. One of the electrodes for the lamp was hermetically sealed through and insulated from the metallic base. The other electrode was in metallic connection with the metal base. The two electrodes were furnished with a small carbon clamp at their extremeties, into which a U-shaped carbon was inserted and firmly held. This formed the other part of the lamp. The cup with its attached globe was passed over the carbon and electrodes of the lamp and united to the metallic base and soldered thereto, forming a tight joint. That is a description of the lamp.

10 X Q. When you went into the employment of the Consolidated Electric Light Company what lamps were they manufacturing?

A. They were not manufacturing any. They commenced the manufacture of the lamp of which I was the inventor.

11 X Q. At what time was this?

A. They commenced it when I went there, which was somewhere about the 12th of October, 1882, when I first began my work there. This was on the corner of Front and Adams streets, Brooklyn.

12 X Q. What was the carbon used in that lamp?

A. Quite a variety of carbons. They were made from paper, kittoal, tampico, istle, patent fibre, bast and bamboo.

13 X Q. What was the material for the carbon adopted for the commercial lamp of the company?

A. Bamboo.

14 X Q. When was this adopted?

A. It was finally decided to use bamboo the 28th of March, 1883.

15 X Q. When were the first commercial lamps put on the market to your recollection?

A. The first lamps we put on the market were put in the United Bank building, corner of Wall and Broadway. I can't give the exact date. I have got it but not here.

16 X Q. These were bamboo lamps, were they not?

A. Bamboo.

1817 17 X Q. How did the bamboo carbons in your lamps differ from the bamboo carbons used in the Edison lamps?

A. They had no lugs on the extremities and were much heavier and lower in resistance, and were treated loops—treated carbons.

18 X Q. Later on, how did the carbons used by you differ from the Edison bamboo carbons?

A. They never had any terminal lugs, were round in section, treated and of a lower resistance than the Edison carbon.

19 X Q. The treatment lowered the resistance, did it not?

A. It did, more or less. The carbons when carbonized and before treatment were always of quite low resistance, comparatively speaking. The treating process was principally used to equalize the resistance of the carbons and make them uniform.

20 X Q. How did you come to leave the employment of the Consolidated Company?

A. They got through with my services and didn't need me any longer.

21 X Q. What do you mean by saying they "got through" with your services?

A. There were several of us that could not agree very well and it was decided that we had better part.

22 X Q. Wasn't there quite a row?

A. Not particularly. They informed me that they did not need my services any longer. I tendered my resignation, which was accepted.

23 X Q. Have you been retained as an expert in this suit?

A. I have.

24 X Q. How long ago were you retained?

A. I don't remember exactly. About a month ago.

25 X Q. Do you expect to testify again in this suit?

A. I shall, if I am asked so to do.

1818 26 X Q. You have no knowledge of any intention to call you again, have you?

A. I don't know anything about it.

27 X Q. Do you remember my calling at your office in Brooklyn in company with Mr. Vineing?

A. I do.

28 X Q. Did you not then state to me in substance that in consequence of your retainer you must refuse to give me information as to the matters of which I inquired?

A. Not knowing who you were I did. It is not my habit to give information to anybody I am not acquainted with, unless for some special reason.

29 X Q. You recognized Mr. Vineing, did you not?

A. I did.

30 X Q. And I informed you that I was attorney for the Edison Electric Light Company, did I not?

A. I did not so understand you. I understood that you were connected with the Edison Company in some capacity, from what Mr. Vineing said when he introduced you.

31 X Q. And you told us that the Edison Company couldn't get anything out of you, substantially, wasn't that it?

A. Not substantially. I had just been retained by the Westinghouse people, and I did not consider that I was at liberty to converse with other people on the subject for which they had retained me.

32 X Q. For what subject had they retained you?

A. For general electrical work, I suppose, but more especially on incandescent lamps and kindred subjects.

33 X Q. Have you done any general electric work further since your retainer?

A. Not any.

34 X Q. Have you done any work especially on electric lamps and kindred subjects since your retainer?

A. Nothing. This is my first appearance in their interest to-day.

1819 Redirect:

35 R. D. Q. Do you consider yourself qualified to testify as an expert on the general subject of electric lighting and especially of incandescent electric lamps?

A. I do.

36 R. D. Q. Since you were retained in this case, have you had any conferences with Mr. Broadnax on the subject of incandescent electric lamps, in making such lamps and especially carbons?

A. I have.

E. R. KNOWLES.

NEW YORK, *April 13th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr of counsel for complainant, and Walter K. Griffin of counsel for defendant.

Testimony of James A. Vandegrift.

JAMES A. VANDEGRIFT a witness on the part of complainant being duly sworn testifies as follows in answer to interrogatories propounded to him by Mr. KERR:

1 Q. State your name, age, residence and occupation.

A. James A. Vandegrift, 27, my place of residence, Newark, N. J.; I am a manufacturer of incandescent electric lamps.

2 Q. Please state the name of the company you are connected with, and how long you have been connected with it?

A. United States Electric Lighting Company, since January 20th of 1880.

1820 3 Q. Have you been engaged in the manufacture of lamps for that company ever since that date?

A. With the exception of two years.

4 Q. What two years?

A. 1882 and 1883.

5 Q. Please state what kind of lamps the United States Company was manufacturing, if any, at the time you were there, namely, January 20th, 1880?

A. The lamp contained a carbon composed of paper treated with a hydrocarbon vapor.

6 Q. Please state what kind of lamps so far as the carbon is concerned, the United States Company has been making and selling since January 20th, 1880?

A. Two kinds, one with a carbon composed of paper and the other kind with a carbon of tamadine.

7 Q. Please state when the United States Company began to manufacture lamps from tamadine?

A. Some time during the year 1883.

8 Q. To what extent has the manufacture of paper-carbon lamps been carried on, to your knowledge, by the United States Company since January 20th, 1880?

A. They manufactured since 1883 in the neighborhood of eight hundred thousand. From 1880 until 1883 they were making between two and three hundred a day as an average.

9 Q. State whether the United States Company is still making and selling lamps with paper carbons.

A. It is.

10 Q. Please produce specimens of paper-carbon lamps made by the United States Company during the period from January 20th, 1880, to the present time?

A. I now produce two lamps, having carbons of different forms, one with a letter M carbon and one with a zigzag carbon, which are samples of the two types of paper-carbon lamps made by the United States Company during that period.

1821 The two lamps produced by witness are offered in evidence and marked "Complainant's Exhibit U. S. Zigzag Lamp," and "Complainant's Exhibit U. S. M-shaped Lamp, W. T. F., special examiner, April 13, 1889."

11 Q. Is the United States Company at present manufacturing and selling both of these forms of paper-carbon lamps?

A. They are.

12 Q. State whether these are practical and commercial lamps.

A. They are.

Cross-examination by Mr. GRIFFIN:

13 X Q. What experience had you in the manufacture of incandescent electric lamps prior to January 20th, 1880?

A. None.

14 X Q. Or as to the manufacture of carbons prior to that date?

A. None.

15 X Q. You were about 20 years of age when you went to the factory, were you not?

A. Yes.

16 X Q. What have been your successive positions in the factory?

A. Assistant to Mr. Maxim; in charge of the incandescent department; erecting plants; again in charge of the incandescent department.

17 X Q. In the M-shaped lamp you have presented, is not the shape of carbon covered by letters patent to Mr. Maxim?

A. I believe it is.

18 X Q. Is not the zigzag shape in the second lamp presented by you, also patented to Mr. Maxim in this country?

A. My understanding is that it was patented by Mr. Weston.

1822 19 X Q. What kind of paper originally before carbonization were the conductors of these two lamps formed of?

A. Called parchment deed paper.

20 X Q. Is not the use of parchment paper patented by Mr. Weston in the United States?

A. I have no knowledge of such a patent.

21 X Q. Are the paper conductors in the two lamps treated or non-treated?

A. They are treated.

22 X Q. By whose process?

A. Mr. Maxim's.

23 X Q. Patented to him in the United States, is it not?

A. Yes, sir.

24 X Q. What is the difference in the weight of those paper conductors before and after treatment?

A. I should say 10 per cent. heavier after treatment.

25 X Q. Is the paper prepared or treated prior to carbonization?

A. Only very slightly charred, for the purpose of punching better.

26 X Q. What do you mean by very slightly charred?

A. Heated between copper plates, and raised to a temperature to slightly brown the paper.

27 X Q. This has the effect of charring or consuming all loose, exterior fibres, has it not?

A. No; it is simply for the purpose of allowing the punch to make a clean cut.

28 X Q. You mean by making a clean cut making a cut without dragging out or teazing out the fibres on the edge of the filament, do you not?

A. Yes.

29 X Q. What temperature are these copper plates heated to for the process of partial carbonization?

A. About 250 degrees Farenheit.

30 X Q. Who invented this process?

1823 A. Mr. Maxim.

31 X Q. And it is patented to him in the United States?

A. I don't remember a patent issued to him for this.

32 X Q. By what means are the papers carbonized? I mean who invented the process used by the United States Company?

A. Mr. Maxim.

33 X Q. Has he any letters patent of the United States for any of the processes or means of carbonization?

A. He has.

34 X Q. And these processes invented by and patented to Mr. Maxim are used by the United States Company?

A. They are.

35 X Q. In the M lamp I notice a special means for attaching the ends of the carbon to the twisted electrodes consisting of miniature nuts, bolts and washers. Whose invention is this?

A. Mr. Maxim's.

36 X Q. And the twisted electrodes, whose invention are those?

A. I don't know.

37 X Q. How many letters patent of the United States upon the method of sealing lamps do you know?

A. I know of four.

38 X Q. How many of those patented processes are made use of in sealing the M lamp? I mean by sealing and so forth, the processes or means of fixing the electrodes in the inner bulb and the means of fusing or attaching the inner bulb to the outer bulb.

A. Two processes.

39 X Q. How many patents has the United States Company, so far as you know, on the methods of procuring a vacuum and sealing or fusing the outer globe to secure the vacuum?

A. I am aware of only one.

1824 40 X Q. Do you know whether there is only one patent or is there only one patent of which you are now aware?

A. I only remember one patent.

41 X Q. There may be more patents for all you know?

A. Yes, sir.

42 X Q. In the zigzag lamp presented by you, the method of supporting the electrodes is different from the methods shown in the M lamp. How many patents, if any are there upon this method of sealing the electrodes in the zigzag lamp?

A. One.

43 X Q. Have you any definite knowledge as to the number of patents, or of inventions made since January 20th, 1880, used by the United States Company in connection with the system of manufacture and use of these paper-carbon lamps?

A. I have no definite knowledge.

44 X Q. Before carbonization, is the paper submitted to pressure of any kind?

A. Yes.

45 X Q. Describe the means by which that pressure is applied.

A. An ordinary screw-press with a hand wheel.

46 X Q. Have you any idea of the number of pounds pressure to the square inch they applied?

A. I have not; but it is only to keep the paper from wrinkling during the process of charring. This pressure is applied during the process of charring.

47 X Q. How many paper lamps of this size do the United States Company now manufacture?

A. Between seven and eight hundred per day.

48 X Q. How does this compare with the number of tamadine lamps?

A. About one-quarter.

Cross-examination closed.

JAMES A. VANDEGRIFT.

1825 Boston, *April 1st*, 1889.

Testimony Taken on Behalf of Complainant, Before H. C. Merwin, Special Examiner, Pursuant to Agreement of Counsel.

Present: L. E. Curtis, Esq., for complainant; R. N. Dyer, Esq., for defendant.

It is stipulated and agreed that proofs may be taken on behalf of complainant before H. C. Merwin, notary public, with the same force and effect as if taken before one of the standing examiners of the court, and that an order may be entered *nunc pro tunc* at any time, without notice, appointing said H. C. Merwin a special examiner herein.

Adjourned to April 2, at 11 a. m.

Boston, *April* 2, 1889.

Met pursuant to adjournment.
Present: Counsel as before.

Testimony of Charles R. Cross.

The witness, Prof. Charles R. Cross, a witness produced on behalf of complainant, being duly sworn and interrogated by counsel for complainant, deposes and says as follows:

1826 Int. 1. What is your name, age, residence and occupation?

Ans. Charles R. Cross; 41 years of age; I live in Boston, Mass., and am Thayer professor of physics in the Massachusetts Institute of Technology.

Int. 2. What knowledge have you of the science of electricity and of the various applications of electricity to the useful arts, and particularly the art of electric lighting?

Ans. During the past nineteen years, in the position which I have occupied at the Massachusetts Institute of Technology, I have constantly been required to give extended instruction in the study of electricity, both theoretical and applied. I have, during a large portion of that time, given special courses of lectures relating to applied electricity, and particularly to the theory and practice of electric lighting, both to my own classes and in public. I am director of the Rogers laboratory of physics in the institute of tech-

nology, and have under my care the large collection of apparatus for electrical measurement and testing belonging to that laboratory, and have the direction and superintendence of the work of instruction and research which is constantly carried on in that laboratory. About six years ago, at my suggestion, a course in electrical engineering, the first to be established in this country, was instituted in the institute of technology, and since that time, by far the greater part of my time has been occupied in the development of that course. In this connection, I have immediately under my care the instruction of students, both in the lecture-room and laboratory, in the study of technical electricity, and a very great portion of that instruction is devoted to different branches of electric lighting, which I am accustomed to treat with minuteness. I have personally, and in connection with my advanced students, made numerous researches in electricity, and especially in its application to the telephone and to electric lighting, and have published a number of papers thereon. I have several times served upon juries
1827 called to decide upon the relative merits of electric lamps,
dynamo machines and other devices used in electric lighting, and have become familiar with the various systems of electric lighting which have been proposed or used. I have frequently, during the last eleven years, given testimony in the United States courts regarding electrical inventions, and have testified in almost all of the principal suits relating to the electric speaking telephone, and also in numerous suits relating to electric lamps and electric lighting. I have kept myself informed as to the development of the incandescent electric lamp and its employment for electric illumination, and am familiar with the history of this branch of the art. I am acquainted with the various devices which have been proposed or used for this purpose.

Int. 3. Have you read and examined the complainant's patent in suit, U. S. letters patent No. 317,676, granted May 12, 1885, to Electro-Dynamic Light Co., of New York, assignee of William E. Sawyer and Albon Man, and do you understand the same?

Ans. I have read the patent referred to, and believe that I understand it.

Int. 4. What were the principal kinds of electric lamps known in the art prior to 1880, and which of these, if any, had been used for any industrial purpose?

Ans. There were three kinds of electric lamps which had been described prior to the date mentioned in the question. These lamps were, first, the arc lamp; second, the arc incandescent, or semi-incandescent lamp; and, third, the incandescent lamp.

The first of these makes use of the voltaic arc, which is produced when a current from a voltaic battery or dynamo machine of proper construction is caused to pass between two pencils of hard carbon, first brought into contact and then separated from each other by a short distance. The current of electricity leaps across the gap between the two carbons, producing an intensely brilliant light,
1828 the most brilliant artificial light known. The greater part
of this light comes from the ends of the pencils themselves,

which become heated to an intense whiteness, and glow with great brilliancy.

A description of this phenomenon, together with a picture of the voltaic arc, will be found on page 4 of a book entitled "Electric Lighting" by H. Fontaine, translated by Paget Higgs, published in London in 1878.

In the arc incandescent, or semi-incandescent lamp, one piece of carbon, generally brought to a point, is allowed to rest lightly upon a second piece of carbon. Owing to the higher resistance at and near the point of contact, the carbon becomes incandescent, and emits a continuous light. A gentle pressure is exerted between the two carbons, so that the contact is still kept up, notwithstanding the wasting away which occurs from ordinary combustion and other causes. The lamp of Shepard, shown in British patent No. 13302, of 1850, Defendant's Exhibit No. 20, is a lamp of this kind, as is also the well-known Werdermann lamp.

The incandescent lamp is a lamp in which a piece of platinum, iridium, carbon, or other refractory-conducting material, is brought to incandescence by the passage through it of a current of electricity, which causes it to emit a steady glow. Of this character is the lamp described by King in British patent No. 10919 of 1845, Defendant's Exhibit No. 17.

A picture of this lamp is shown in Fig. 45, page 170, of Higgs' book already cited.

The arc lamp is the only one of these which had been used for any industrial purpose at the date referred to in the question. It had, however, been so used for many years, being especially well known in connection with light-house illumination; so that the term "electric lighting" was always understood as referring to illumination by means of the arc light. A picture of one of the best
known electric lamps which had been used prior to 1880, the
1832 Serrin regulator, is shown in Fig. 9, page 31, of the Higgs
publication. It was especially employed in some of the
French light-houses, though its use was by no means limited to this.

Adjourned to 2.15 p. m.

Resumed after adjournment at 2.15.

Complainant's counsel offers in evidence the cuts referred to in the preceding answer, and the same are marked, respectively, Complainant's Exhibit Cut of Voltaic Arc; Complainant's Exhibit Cut of Serrin Arc Lamp; Complainant's Exhibit Cut of Werdermann Arc Incandescent Lamp; and Complainant's Exhibit Cut of King Lamp; H. C. M., spe. ex.

(Here follow diagrams marked pp. 1829, 1830, and 1831.)

Int. 5. Did the term "charcoal," prior to 1880, have any different signification in the art of electric lighting, from its popular signification of wood charcoal prepared by the ordinary methods of

[illegible] urner; and if so, please state what such different [illegible], and how it arose.

[illegible] he date referred to in the question the word char- [illegible] monly used in the art of electric lighting with a [illegible] rent from that in which it is popularly used. [illegible] designate the hard gas-retort carbon out of which [illegible] ons pencils used in the production of the electric [illegible]

[illegible] rm arose, apparently, in some such manner as [illegible] en the electric light was produced by Davy and [illegible] rimenters, they made use of hard charcoal, gen- [illegible] arcoal, which they shaped into pencils of proper [illegible] never satisfactory, since they were very rapidly [illegible] d, largely owing to this peculiarity, no use was made [illegible] arc, except as a lecture-room experiment, for many [illegible] But about 1845, Foucault suggested the employment [illegible] encils made from the hard carbon which is formed on the [illegible] terior of gas retorts, which is like graphite, very dense, and [illegible] wastes away very slowly, when used for the material of the pencils between which the arc is formed. For this, in later times, was substituted artificially prepared pencils made by pulverizing coke or gas-retort carbon, mixing it with some suitable material, such as tar, which would cement the particles together, forming them into a pencil shape in moulds, and heating them so as to consolidate the whole into a hard pencil.

The term charcoal, originally applied to the pencils of ordinary boxwood or similar charcoal used by Davy and others, not unnaturally came to be applied to the material of the carbon pencils employed in the arc light, without regard to the particular kind of carbon employed, the term charcoal being used in a generic rather than in a specific sense; and hence continuing to be applied to the material of the pencils for arc lighting long after the ordinary form of charcoal had ceased to be used for that purpose.

There is also still another way in which apparently the word charcoal has come to be used as, in general, identical in meaning with the word carbon, and especially as applied to the hard gas-retort carbon employed in arc lighting. There are many cases in which descriptions of pencils of carbon of this kind have been originally described in patents or other publications written in the French language and which have subsequently been translated into English. In many of these, the French term "charbon" has been rendered in English as "charcoal."

I will proceed to give a number of illustrations of the use of the term charcoal, to which I have referred.

In a paper by Violette (Defendant's Exhibit No. 11, Violette Paper), find this statement.

"Charcoal made at 1,500 degrees centigrade conducts much better than the charcoal of gas retorts and serves perfectly for electric illumination."

1834 In the English patent to Shepard, No. 13302 of 1850 put in evidence by defendant, page 9, I find the following descrip-

tion, which refers to a form of arc incandescent or se
lamp presented by the patentee as the inventio
Nollet of Brussels."

"6. Apparatus for lighting in a va

When it is desired to light by means of t
charcoal, I employ an arrangement of appara
which is represented in Fig. 10. A is a globe
if desired, be ground or obscured on the inside,
and soften the intensity of the light. The stop
is very carefully luted and two insulated polar
about 2 millimetres in diameter, are passed th
these wires is soldered to the side and towards the
copper tube C, of about 1 decimetre (4 inches) in leng
is intended to hold a little cylinder of *charcoal*, which
stantly pushed down from above by a small cylinder of
is of a weight adjusted to the purpose. The other polar wi
out under the lower end of this tube at about 1 centimetre (
inch) distance from its extremity, and terminates in a little cone
of prepared *charcoal* or coke, and against the top of which the little *charcoal* cylinder E rests, which, when the current is established, becomes incandescent, and remains in that state a very long time, because the small portions which are consumed are continually replaced by a portion of the cylinder, which the metal presser forces on to the top of the cone."

The italics in the preceding quotation are my own, and do not occur in the original.

There is also a Belgian patent to F. Nollet, filed May 5, 1851, and granted Nov. 4, 1852, which covers the same ground as the Shepard English patent just referred to, and of which the
1835 latter is substantially a translation. In this Belgian patent
I find the following paragraph, which corresponds to the one which I have quoted from the English patent:

"Lorsque je veux éclairer au moyen de l' incándescence du charbon, je dispose l' appareil qui est représenté Fig. 8 et qui se compose d' un ballon de verre dépoli si on le veut à l' intérieure pour adoucir la trop grande intensité de la lumiére. Le bouchon de ce ballon très soliditement luté est traversé par les deux fils polaires P. N. isolés d' environ deux millimètres de diametre. Un de ces fils est soudé à la paroi latérale et vers l extremité supérieure d' un tube de cuivre d' environ un dècimétre de lengueux et d' environ trois millimètres de diamètre. Ce tube est destiné à recevoir un petit cylindre de *charbon* comme il est dit cidessus, et constamment poussé de haut en bas par un petit cylindre de plomb qui a le poids nécessaire pour pousser suffisamment le *charbon*. L' autre fil polaire se présente sous l' extremite inférieure de ce tube et a environ un centimètre de son extrèmité. Il se termine par un petit cône *b* de *charbon* préparé de quatre à cinq millimétres de base et au sommet duquel vieut appayer légèrement le petit cylindre de *charbon* ou coke qui lorsque le courant est établi devient incandes-

[illegible] nt dans cet état très longtemps puisque les petites
[illegible] ent se consommer sont constamment remplaceés
[illegible] cylindre que le metal presseur pousse constam-
[illegible] t du cone."

[illegible] e above quotation from the Belgian patent are
[illegible] observed that the word "charbon" in the Bel-
[illegible] ted "charcoal" in the English patent. Fig. 8
[illegible] e Belgian patent is substantially the same as
[illegible] English patent.

[illegible] ish patent to Binks, No. 119 of 1853, put in evi-
[illegible] defendant, the electrodes employed in arc lamps
[illegible] rods or pencils of solid charcoal;" and through-
[illegible] se arc-light carbons are referred to as made of
[illegible] n the ordinary gas carbon is undoubtedly intended,
[illegible] years prior to 1853 it was well recognized that com-
[illegible] was unfitted for such purposes, and could not prac-
[illegible] ed. In the same patent Binks describes the employ-
[illegible] carbonized lignite, and speaks of this product as a
[illegible] al.

Binks also at the very beginning of his patent uses the term charcoal to denote the form of carbon used in ordinary electric arc lighting. He says:

"In the ordinary arrangements of the carbon electrodes for producing light by a current of voltaic electricity, two rods or pencils of solid charcoal are used."

In the English patent to Way, No. 2547 of 1856, put in evidence by defendant, the patentee refers to the ordinary hard-carbon electrodes as "electrodes of charcoal." He says: "Heretofore in obtaining light by means of electricity, electrodes of charcoal have usually been employed," and goes on to describe a use of mercury in connection with his lamp.

The same Way, in British patent 2841 of 1857, also put in evidence by defendant, throughout this patent constantly refers to the carbon electrodes described in his earlier patent, just referred to by me, as made of charcoal, although hard carbon is unquestionably the substance intended.

In Harrison's English patent, No. 588 of 1857, in both the provisional and complete specification-, the patentee employs the term charcoal with reference to gas carbon. Thus he says: "It is well known that condensed gas carbon, from its great purity and density, is the best and most durable form of charcoal for the display
1837 of electric light." This paragraph occurs alike in both the provisional and complete specification-. In another case, when the patentee desires to refer specifically to charcoal made by carbonizing ordinary wood, he refers to it as "wood charcoal." The statement is as follows: "I form pencils or solid carbon electrodes, by suspending small rods or pencils of wood charcoal upon a frame of iron:" and goes on to describe his special process of carbonizing.

Burleigh and Danchell, in British patent No. 3164 of 1857, also use the term charcoal in the same sense as referring to the pencils

used in electric arc lighting, and describe a proces
carbon pencils are made from various forms of
gas carbon, by a process of moulding.

In Ure's Dictionary of Arts, Manufactures and
published in New York in 1866, on page 486,
"Electric Light," I find this statement:

"The voltaic battery has been employed a
tricity, and in nearly all the arrangements
lights produced between the poles, from the
charcoal, has been the illuminating source. O
culties in applying this agent arises from the
there is a transference of the charcoal from one
and consequently an alteration in the distance be

The "hardest charcoal" referred to is gas carb
use at that time for the purpose in question.

In the translation of the Gauduin French patent,
evidence by the defendant, it is stated that certain ch
sils, as well as the pencils used in arc lighting, should be
chemically pure carbon, and goes on to say, "Now the dust of
carbon, though containing but a small proportion of foreign matte
is not sufficiently pure for these uses." The translator has
1838 written in the margin opposite "retort carbon," the words
"retort charcoal," as explanatory of the meaning of the
French terms translated as "retort carbon."

From these illustrations I think it is clear that the term "charcoal" was in common use in the art of electric lighting as denoting other forms of carbon than that which is popularly known as charcoal, and especially as denoting the hard carbon used for the purposes of arc lighting.

Int. 6. Is the substance lignite mentioned in the Binks English patent, to which you have referred, a vegetable or a mineral substance?

Ans. It is a mineral substance.

Int. 7. Professor Brackett, defendant's expert, says in substance in his answer to question 5, "that in view of the prior patents and publications, put in evidence by the defendant, there is not, in his opinion, any novelty in the use of vegetable fibrous carbon as the incandescent conductor of the lamp of the patent in suit;" and Prof. Barker in his answer to question 9, agrees with him in the opinion so expressed.

Do you agree with this opinion of defendant's expert? Please read in addition to the questions and answers I have referred to, Prof. Brackett's answers to cross-questions 41, 42 and 43, and Prof. Barker's answers to question 47 and cross-questions 51–55 inclusive, and to cross-question 63, and give your reasons for any opinion you may express.

Adjourned till April 3d, 9.30 a. m.

April 3d—9.30 a. m.

Ans. I do not agree with the statements of defendant's experts referred to in the question. I have considered very carefully

s prior patents and publications put in evidence by
and neither in these nor in any other publica-
am acquainted do I find the use of vegetable
scribed in the Sawyer and Man patent in suit

ling the views which I entertain in opposition
ndant's experts can best be made clear by a
arious patents and publications which the de-
idence. It will simplify matters if I group to-
and publications in evidence.
bits Nos. 1–14 inclusive, comprehending the
n the Philosophical Transactions, the collected
phrey Davy, the articles from the American Jour-
ndus, and Watt's Dictionary of Chemistry, are sim-
s of interesting and important scientific investiga-
periments, but which neither describe electric lamps
to do this. Many of them have no relation whatever
descent lighting, and some have no relation to any kind of
g whatever, the object of the experiments described therein
eing in some cases of purely theoretical interest, and in others relating to arts which are widely different from electric lighting.

Several of these papers relate solely to processes of carbonization, and merely show the state of the art so far as carbonization in general is concerned, but without regard to the bearing of this subject on electric lighting by incandescence.

A second group of the exhibits relates only to arc lighting and to the preparation of carbons for this purpose. Such are the patents to Slater and Watson (Defendant's Exhibit No. 21), an English patent; Binks' English patent (Defendant's Exhibit No. 23); Harrison's English patent (Defendant's Exhibit No. 25); Burleigh and Danchell's English patent (Defendant's Exhibit No. 26); Le Molt's French patent (Defendant's Exhibit No. 37); and the Gauduin
1840 French patent with certificates of addition (Defendant's Exhibit No. 40). These throw absolutely no light upon the selection or use of fibrous carbon for incandescent lighting. On the contrary, so far as they have any effect whatever, they tend to lead one in precisely the wrong direction. The requisites of carbon suitable for arc lighting are quite the reverse of the requisites for carbon to be employed in incandescent lighting. The carbon pencils for arc lighting should be exceedingly hard and very incombustible, so that they may wear away but slowly in the air; and they should moreover have as slight a resistance as possible, in order that it may not interfere with the passage of electricity along their length. In arc lighting the work should all be done in the arc itself, and whatever resistance is offered to the passage of electricity through the pencils is a dead loss; and this is by no means a matter only of theoretical interest. On the contrary, it is practically very important, so that the custom is almost universal of electroplating carbons for arc lighting with copper, in order to diminish the resistance which is offered to the passage of the current through the length of the conductor. Such is evidently not the

case with the incandescent light, since the incan
ment or pencil is to be rendered incandescent th
length, and must therefore offer a high rather t
to the passage of the current throughout its w

A third set of patents and publications rela
descent or similar lamps, which are not, pro
descent lamps. These exhibits are Defend
Pinkus English patent; No. 6, De Moleyn's E
Greener & Staite's English patent; No. 20, S
ent; No. 24, Way's English patent; No. 27, W
No. 29, Konn's English patent of 1873; No. 32,
lish patent; No. 33, Varley's English pa
1841 ties for an arc incandescent light, or for an
ferred to in these patents, are very diffe
arising in incandescent lighting, and there is not
these patents which in any way directs the attention
towards the matters set forth and described in the Sawy
patent in suit.

A fourth group of devices comprehends those described
fendant's Exhibit No. 19, Staite's English patent, and No. 34, Ga
diner and Blossom's U. S. patent. These relate to incandescent lamps, but not to incandescent lamps employing carbon conductors, since both of the patents in question set forth the use of conductors of metal only.

The only exhibits introduced in evidence by the defendant which refer to incandescent lamps with a carbon incandescing conductor, are the following: No. 17, King's English patent; No. 22, Robert's English patent; No. 28, Konn's English patent of 1872; No. 30, Kosloff's English patent; No. 31, Jensen's English patent; No. 35, Kosloff's U. S. patent; No. 38, Mechanics' Magazine article, describing the King lamp; No. 39, Journal of the Society of Arts article, referring to the Lodyguine lamp. Among all of these lamps there are three only which are alleged by defendant's experts to set forth the use of any particular kind of carbon, and it is therefore evident without further consideration that the others could in no way direct one wishing to practice the art of incandescent lighting towards the use of that particular kind of carbon referred to in the Sawyer and Man patent in suit. With regard to the three particular patents to which I have referred, I find them exceedingly indefinite, ambiguous, and calculated to confuse rather than to enlighten the mind of one reading them. I think that the justice of my conclusion will better be made evident by a specific though brief consideration of them.

I will consider first the British patent to Konn, No. 3809, of 1872. In this patent, which is a communication from Lodyguine of St. Petersburgh, there are described several forms of incandescent
1842 lamp in which carbon is used as the incandescing conductor.
The only particular form of carbon which is referred to in the patent is graphite, the patentee saying that the incandescing conductors are to be made "preferably of graphite." This lamp is referred to by defendant's expert, Prof. Barker, in his answers to

question 47, and cross-question 53. From the fact that Konn states that the incandescing conductors for his lamp are to be made "preferably of graphite," it seems to me unquestionable that his intention was, and that the effect of his patent necessarily would be, to guide one reading it and desiring to put into practice the invention therein set forth to the use of such graphite or gas carbon as was well known in the arts in connection with electric lighting. It is practically a statement that to get the full benefit of his invention one must employ that kind of carbon which possesses those peculiarities which were known to be possessed by graphite, especially, among different kinds of carbon. There is not in the patent the remotest intimation that anything but disadvantage could result from using carbon other than graphitic carbon; and an electrician wishing to construct an incandescent lamp of the character subsequently invented by Messrs. Sawyer and Man, and set forth in the patent in suit, would have to turn his back upon the patent to Konn and walk directly away from it and from everything which it contains in order to reach his goal.

I observe that Prof. Barker draws a different inference from my own in regard to the statement of Konn's that his incandescing conductors were to be made "preferably of graphite." Prof. Barker states that to him this "clearly indicates" that "Konn was fully aware that carbon in other forms was suitable for the purpose, and that these other forms had already been known and used as incandescing conductors for electric lamps." It does not seem to me that Konn's statement justifies the conclusion which Prof. Barker draws from it. On the contrary it appears to me that whatever Konn may or may not have been aware of, he intended to state, 1843 and does distinctly state, that for an incandescent lamp, such as he describes, graphite is pre-eminently the thing to be used, and that other kinds of carbon are distinctly not the things to be chosen by one wishing to practice his invention.

Adjourned till 2.10 p. m.

2.30 P. M.

The "Golos article" referred to in an article in the Journal of the Society of Arts, for Aug. 22, 1873, Defendant's Exhibit No. 39, relates to certain experiments with a lamp of Lodyguine. There is no scientific description of the lamp, but only a brief, popular statement which shows that it was an incandescent lamp having a carbon conductor. Referring to this lamp, the article says "only one piece of charcoal or other bad conductor is required;" and the same term "charcoal" is applied to the conductor in the latter portion of the same sentence, and once again in a subsequent sentence in which it is stated that "the charcoal becomes gradually and equally heated." The word "charcoal," as used in this publication, however, does not denote any kind of fibrous carbon, as will immediately appear from the consideration of the manner in which the same word is used somewhat earlier in the same article. Referring to the electric arc, it is spoken of as being formed "between two points of charcoal," and it is further said that difficulties arose from "the rapid consumption of the charcoal points." There can be no question, therefore, that the word "charcoal," as used in this publication, in no way refers to fibrous carbon, but rather to the hard gas-retort carbon which, at the date of publication of that article, had for many years in Russia as elsewhere been employed in arc lighting.

That I am correct in my view, that the term "charcoal" is employed in this article with reference to gas carbon, will further appear from a consideration of certain English patents
1844 relating to the same or similar forms of lamp, and originating with the same person or his colleagues.

The Golos article refers to Messrs. Kosloff & Co., of St. Petersburgh, as the proprietors of Mr. Lodyguine's patent for this invention, and Lodyguine was apparently connected in some way with this firm.

British patent to Konn, of the firm of S. A. Kosloff & Co., No. 3809 of 1872, Defendant's Exhibit No. 28, which is a communication by A. N. Lodyguine of St. Petersburgh, describes a new form of incandescent lamp, devised by the latter. Throughout this patent, wherever the material employed by it is specifically mentioned, it is stated to be graphite, which I understand to mean the material which had ordinarily been used for arc-light pencils. There are several other patents for incandescent lamps coming from the same firm. Konn's English patent, No. 91 of 1873, describes an incandescent lamp employing "solid stems of carbon," and the behavior of the "carbon stems" in this lamp is contrasted with the behavior of the "carbon points" as used in the arc light: from which I should infer without question that the same kind of carbon, that is hard carbon, was referred to in each case. Also, British patent to Kosloff, No. 441 of 1875, describes another form of incandescent lamp, in which "sticks of carbon" are made incandescent by the passage of a current through them. The specific form of carbon to be employed is not stated in terms in this patent, but I think that there can be no question that the patentee referred to such carbons as were used in electric arc lighting, and that this is the sense in which the patent would be understood. The patentee speaks of "the carbons" of the lamps in precisely the same way in which it was customary to speak of the pencils used in arc lighting as "the carbons," which he would have been very unlikely to do if they had not been of the same character. Also, British patent, No. 970 of 1875, to Jensen, is a communication from Konn of St. Petersburgh. It describes further improvements in the incan-
1845 descent lamp. In this patent the rods are also spoken of as made of carbon.

In none of these English patents is there any reference to any kind of carbon other than graphite, and in the Golos article it is clear, as I have shown, that the word charcoal is used as meaning hard carbon.

The statement in the Golos article reads very much as if translated or paraphrased from the French, and I have an impression that the periodical referred to employs that language; but whether this is or is not the case, it is clear that there is not the slightest reference in the Golos article to the use of fibrous carbon in an incandescent lamp.

British patent to Roberts, No. 14198, of 1852, contains a description of an incandescent lamp employing a conductor of carbon. He generally refers to this conductor as made of graphite. In stating his invention, however, he says, that it "consists of a mode of obtaining electric light by passing a current of electricity through a thin piece of graphite coke or charcoal or other infusible body being a conductor of electricity." This statement seems to be a very general one, and intended to indicate only that some form of conducting carbon should be employed. It certainly does not at all intimate the employment of vegetable fibrous carbon as in the patent in suit.

For the reasons stated I find myself quite unable to agree with the views regarding this matter expressed by Professors Brackett and Barker in their answers referred to in question.

Int. 8. In what sense do you understand the word "charcoal" to be used in the Roberts patent to which you have just referred?

Ans. It seems to me that Roberts merely intended to indicate by his reference the general use of carbon rather than the specific use of any particular kind, and he apparently uses language to indicate several forms of conducting carbon. It seems to me from the particular forms that he mentions, that he perhaps had in mind natural
graphite or plumbago, indicated by the word graphite; arti-
1846 ficial carbons made from pulverized coke, and indicated by
the word coke; and gas carbon as indicated by the word
charcoal. Such a use of terms would be quite in the line of that usage which I have already pointed out in my answer to question 3.

Int. 9. Assuming that the word charcoal in the Roberts patent is to be taken in its popular sense of wood charcoal, does the Roberts patent indicate any preference for such charcoal, or contain any statements which would lead a person skilled in the art to select such charcoal as specially suitable for use as the incandescent conductor of an electric lamp?

Ans. It does not in any way. Charcoal is merely mentioned, and that but once only, in the general statement of invention, as an infusible body which is a conductor of electricity, and the patentee suggests the use of any body whatever of this kind as suitable for his purpose. There is absolutely nothing in the patent to indicate the necessity of the conductor possessing any property except that of being infusible; and the patentee does not indicate any advantage in one of these forms over another, except in so far as his constant reference to graphite would indicate his preference for this; so that, if one reading the patent inferred that the word charcoal referred to the article of commerce popularly known as charcoal, he would in no way be led from anything in the Roberts patent to employ such charcoal in preference to any other form of carbon, as, for example, graphite or coke. I should say that, even if he understood the word charcoal to be used in its popular sense, as indicated in the question, the statements of the patent would lead him to employ the more infusible and less destructible forms of carbon mentioned therein, and especially graphite, which is the particular form most frequently referred to.

Int. 10. Assuming that the term charcoal, as used in the 1847 Roberts English patent, and in the description of the Lodyguine lamp published in the London Journal of the Society of Arts, is to be taken as meaning the article of commerce popularly known as charcoal, would either of these, in your opinion, constitute a description of the use, in an electric lamp, of the incandescing conductor of carbonized fibrous material of complainant's patent in suit?

Ans. It would not. What is popularly known as charcoal is a material not fitted for use as the incandescing conductor of an incandescent lamp. It is imperfectly carbonized, uneven in its structure, and its electrical resistance would be irregular. All of these qualities tend to render it ill-fitted for use in an incandescent lamp. Moreover, in shaping the conductor it would be necessary to cut across the fibres, which would be very undesirable, and would seriously interfere with its utility. It might be possible to produce an incandescing conductor made from the charcoal of commerce, which could be used for a short time in an incandescent lamp, but, if possible, this could only be done as a sort of "tour de force" of the skilled workman undertaking it, and it could not be made commercially useful. What is popularly understood as charcoal is a very different thing from such carbonized fibrous material as is set forth in complainant's patent in suit, which implies a perfectness of carbonization and a choice of material not found in the charcoal of commerce, and not suggested by the use of that term.

Int. 11. Do you agree with the opinion expressed by defendant's expert, Prof. Brackett, in his answer to question 5, that the advantages of the arch or horseshoe form of an incandescent conductor for an electric lamp are present, whatever may be the material, whether it is metal or carbon?

Ans. I do not agree with Prof. Brackett in this opinion. A very important advantage of the horseshoe form with carbon consists in the fact that it permits the material to readily alter its shape with change of temperature. With platinum, or any other 1848 metal which is not brittle, this is an unimportant matter, since the metal readily bends, more or less, as is necessary to adapt itself to the conditions of stress which arise within it when its temperature changes. Hence, with metal as an incandescing conductor, so far as this particular point is concerned, it makes no difference whether the conductor is straight or arch-shaped; but with carbon as an incandescing conductor, the reverse is the case. This material is brittle, and cannot adapt itself to any material extent to such stresses as are produced by its change in temperature. It is therefore exceedingly liable to breakage from expansion or contraction if it is used in the form of a straight strip. Liability to rupture from this cause was well known in the arts at the date of the Sawyer & Man patent in this suit, and is frequently referred to in various patents and publications. It is, moreover, referred to at length in the Sawyer & Man patent in suit.

It seems to me, therefore, that there is clearly a great value in the arch-formed incandescing conductor, as contrasted with all other forms of conductor in incandescent lamps when carbon is used for that conductor, which does not exist in incandescent lamps employing metal as the incandescing conductor.

Int. 12. Do you agree with the opinion expressed by Prof. Brackett in his answer to question 33, and by Prof. Barker in his answer to question 43, that the advantage to which you have just referred is not present in the lamp described in the patent in suit, but that the conductor there shown and described is as liable to fracture in the arch form shown as it would be in the form of a straight rod?

Ans. I do not agree with Profs. Brackett and Barker in this opinion. On the contrary, it seems to me evident that the arch-shaped form is one which produces much less tendency to rupture when the carbon is heated or cooled than if it were straight. I do not see that the mere fact, suggested by Prof. Brackett, that the conductor is a somewhat thick one, deprives the arch-shape conductor of its confessed value. A thick filament would very likely 1849 be more brittle, other things remaining the same, but such brittleness would be more harmful in a straight conductor than in an arch-shaped conductor. Moreover, my understanding has been that it was a matter of confessed experimental knowledge that the arch-shaped carbon possessed this advantage over the straight carbon.

Int. 13. Do you agree with the opinion expressed by Prof. Barker in his answer to cross-question 53, that the advantages set forth in the patent in suit as belonging to the arch form of incandescent conductor, are secured to the same extent by the form of the said conductor shown in the Roberts English patent?

Ans. I do not. The Roberts patent describes a lamp, containing an incandescent conductor of carbon in which a straight conductor is employed, as I have already explained in my answer to question 7. This straight carbon possesses none of the ability of free expansion or contraction, with change of temperature, which is a special advantage of the arch-shaped form as set forth in the Sawyer & Man patent in suit.

Adjourned till 8 p. m.

Resumed at 8 p. m.

Int. 14. Do you agree with Prof. Brackett in the opinion he expresses in answer to question 35, that in the modern incandescent lamp the advantages arising from the capacity of the conductor to contract and expand without breaking or disturbing the position of the fixed terminals, would be present whatever the form of the conductor, whether that of a loop or of a straight piece?

Ans. I do not agree with Prof. Brackett in the opinion referred to. It seems to me that with a straight carbon fixed at the extremities there would necessarily and evidently be much greater likelihood of rupture than with the horseshoe form; the rigid extremities would not allow the carbon to accommodate itself 1850 to changes in temperature, and the stress produced in it by such change could hardly fail to exert a deleterious influence. I am confirmed in this opinion from the fact that in certain forms of incandescent lamp that I have seen, in which a straight carbon was employed, delicate and complex mechanical arrangements were necessary to suitably support the carbon in order to prevent its breaking. Still further, a straight carbon would be liable to injury in transportation, on account of its greater rigidity to which the horseshoe filament would be much less subject.

Int. 15. Was the liability of the carbon conductor to fracture from the effects of expansion and contraction recognized in the art as a defect of the incandescent lamps having straight carbon conductors which were known prior to 1880?

Ans. It was fully recognized and stated in printed publications, as will be seen, for example, by reference to the description of the electric lamp described by Kosloff in British patent No. 441 of 1875. In this patent the defect in question is described, and a particular device for avoiding the difficulty is also explained. A similar device is also found described in Jensen's British patent No. 970 of 1875. The difficulty under consideration is also alluded to in U. S. patent to Sawyer and Man, No. 210,809, and a device for remedying it is described in that patent.

Int. 16. As a matter of fact, what is the form of the incandescent conductor used in incandescent lamps which have gone into commercial use since 1880?

Ans. In all cases which I recall, of lamps commercially used, the arch-shaped form has been employed. Sometimes a simple arch, as figured in the Sawyer and Man patent, or as used, for instance, in the Edison lamp, sometimes an M-shaped carbon with rounded angles, as in the Maxim lamp, sometimes a sinuous carbon, 1851 as in one of the Weston lamps, and sometimes a helical carbon as in the Swan lamp, have been employed.

Int. 17. Do you agree with the opinion expressed by Prof. Brackett in his answer to question 5, that a V-shaped burner and burners with rectangular bends, instead of curvilinear ones, are described in the patent in suit as equivalent in shape for the arch or horseshoe form?

Ans. I do not. Messrs. Sawyer and Man state that they have used V-shaped conductors, and conductors with rectangular bends, but they distinctly state that they prefer the arch shape; from which I understood that they regard this last as having a distinct advantage over the others, so that these are not equivalents for it.

Int. 18. Do you agree with Prof. Brackett in the opinion he expresses in answer to question 6, that the arch or horseshoe shape described and claimed in the patent in suit, was old in carbons? Please consider in this connection Prof. Brackett's answer to questions 5 and 9, and Prof. Barker's answers to question 14 and to cross-questions 64 and 65.

Ans. I do not agree with Prof. Brackett in his opinion as referred to. In none of the patents and publications which have been put in evidence, nor in any others of whose existence I am aware, is there any reference to the use of an arch shape or horseshoe conductor formed of carbon. The only carbon conductor, other than a straight strip, which is shown in any of the publications put in evidence, is the V-shaped carbon shown in the British patent to Konn, No. 3809 of 1872.

In my opinion, a V-shaped carbon is not an equivalent of the horseshoe conductor of carbon, for there is not the same liberty of free expansion or contraction with the former which exists with the latter, as the two arms of the V would be thrust the one into the other, inducing liability to fracture; also, in such a conductor the lines of flow of the current through the apex of the V would not
be uniform, so that it would become unequally heated at dif-
1852 ferent points, and thus give less satisfactory results than if
the form were that of an arch.

But still more than this, in the Konn lamp under consideration, the incandescing conductor is not the V-shaped carbon as a whole, but simply the apex of the V. The patentee describes the carbons for his lamp as made thinner in the middle; and with reference to the lamp having the V-shaped conductor, says that the current passed down one side of the V and up the other side, "the light being formed at the angle at the bottom." I, therefore, quite fail to see that the use of the V-shape in this lamp is at all material, so far as concerns any of the advantages of the arch form that I have pointed out. It simply allows of a rather more convenient mounting, and avoids shadows. In fact, the two legs of the V are simply conductors of carbon which might perfectly well, so far as the only function that they perform is concerned, be made of metal. Manifestly, therefore, this lamp with the V-shaped carbon gives simply a brilliant spot of light at the angle of the V, and is not in the remotest manner an equivalent for a carbon of horseshoe shape.

Adjourned to April 4, at 9.30 a. m.

April 4, 1889—10 a. m.

Int. 19. Do you agree with the opinion expressed by Prof. Brackett in his answer to question 36, that the primary advantage of using the arch or loop form of conductor in modern incandescent lamps is to allow of great length of conductor?

Ans. I do not. I understand that this form is used chiefly because of the diminished liability to straining and rupture from
changes in temperature or other causes. The horseshoe form
1853 is certainly used in some cases in which a straight filament
of sufficient length could be used without the least inconvenience.

Int. 20. Have you lamps of the kind you have just referred to, and if so will you please produce them?

Ans. I have two such lamps, which I produce. One of these is a lamp made by the Thomson-Houston Electric Company, of Boston, and which is used by them for running in series on the ordinary arc-light circuits. It requires a current of a little less than ten amperes to bring it to a proper state of incandescence. The second lamp is a Bernestein series lamp, also intended to be used on arc-light circuits, and requiring a current of about ten amperes. In both of these lamps the filaments are quite short, but have the usual arch-shape form.

Complainant's counsel offers the lamps referred to in evidence, and the same are marked respectively, Complainant's Exhibit Thomson-Houston Lamp and Complainant's Exhibit Bernstein Lamp, H. C. M., Spe. Ex.

Int. 21. As a matter of fact of what material have the incandescent conductors of such incandescent lamps as have gone into commercial use in this country since 1880 been made?

Ans. In all of them, without exception, carbon is employed. They do not, however, in any case make use of mineral carbon; nor, so far as I am aware, has any attempt been made to make use of mineral carbon in a commercial lamp. In all of those incandescent lamps which have gone into practical use to any material extent, fibrous carbon has been used in the fabrication of the filament, and in all, with the exception of a single style, the fibrous structure is distinctly and evidently maintained.

For example, the Edison lamp employs a carbonized filament of bamboo; the Sawyer and Man lamp uses a filament of carbonized bamboo; the Maxim lamp a filament of carbonized paper; 1854 one of the United States Company's forms of lamps also employs a filament of carbonized paper; the Swann lamp employs a filament of cotton which has been parchmentized; the Westinghouse lamp employs a filament of silk that has been parchmentized. The only lamp which is or ever has been in commercial use, and which does not show an evident fibrous structure, is a form of lamp recently made by the United States Company, which is made of tamadine, a material not known prior to 1880. Tamadine is made by dissolving cellulose in some suitable solvent, as in making ordinary collodion, and the cellulose is then precipitated in a gelatinous state. From this the filaments are cut and afterwards carbonized. This mode of procedure of course obliterates the evident, superficial, fibrous structure of the material, but permits it to retain that ultimate cellulose structure which gives to fibrous or textile material its peculiar value for use in the filament of an incandescent lamp.

Int. 22. Does the process of parchmentization to which you have referred, as used in the process of making some of the filaments, destroy the fibrous structure of the material?

Ans. It does not, it merely serves to consolidate the material and make it denser and more uniform.

Int. 23. Are you familiar with the lamps referred to by Prof. Brackett in his answers to question 31 and cross-questions 67–72, inclusive, redirect question 116, and recross-questions 130–132, and have you taken these lamps into account in your answer to question 21?

Ans. I am familiar with the lamps referred to and did take them into account in my last answer. The Bernstein lamp, which I did not refer to in my answer to the 21st question, employs a filament of woven silk. The vitrite and luminoid lamp makes use of a filament the precise preparation of which I do not know, and which I understand is not made public; it is however fibrous in its character.

1855 Int. 24. Please read Mr. Edison's answer to question 437, and state how far you took into consideration in your answer to question 21 the various processes of making carbon there referred to by Mr. Edison?

Ans. In making that answer I had in mind most of the processes referred to by Mr. Edison. I am not familiar, however, with the use of melassic acid or of the artificially made chemical, to which he refers in that answer. All the other processes mentioned by Mr. Edison in the answer referred to were in my mind when I answered the 21st question.

Int. 25. Have lamps having conductors made of a solution of melassic acid or of the chemical compound or artificially made chemical referred to by Mr. Edison, gone into commercial use at all, so far as you know?

Ans. Not at all, so far as I have any knowledge.

Int. 26. Has the carbonized fibrous or textile material of complainant's patent in suit any special advantages over other forms of carbon for use as an incandescing conductor for an electric lamp, and, if so, in what do these advantages consist?

Ans. It has, as is clearly indicated in that patent.

Thus, by the use of material of this character it is possible to obtain a carbon conductor of exceedingly great purity, and of evenness of texture throughout, so that the conductor will be free from spots, having a greater of less density than that of the conductor as a whole, a defect which when present is a very serious one. Such carbon, moreover, besides its evenness of structure, possesses in virtue of its cellular structure, a high resistance in proportion to its length and section, or what is technically called a high specific resistance. This is an extremely desirable property in such a filament, inasmuch as, for a given strength of current and for a conductor of given length and section, the heating effect is proportional to the specific resistance, so that, to derive a great amount of light from a filament of given size it is desirable that its specific resistance
1856 should be high. This is a well-recognized fact in incandescent electric lighting. Also, fibrous carbon is particularly fitted to undergo such treatment after carbonization as is found desirable in order to harden it and give to it a uniform and definite resistance, which is referred to in the patent as its "susceptibility to tempering." This tempering may be done by treatment with hydrocarbons, or by carrying a strong current through the conductor *in vacuo*, raising it to high incandescence, or by both of these methods combined. Moreover, the carbon of complainant's patent in

suit is naturally firm, elastic and tough. Still more, the carbon of the patent has the great advantage of readily allowing the conductor to be shaped and given the proper dimensions before carbonization, which is a most desirable characteristic. This facility for shaping before carbonization also, of course, carries with it the ability to predetermine approximately and before carbonization the resistance which the conductor is ultimately to have. These are the principal advantages that occur to me as being possessed by the fibrous carbon of the complainant's patent.

Int. 27. Mr. Edison seems to be of the opinion that while the quality of high specific resistance, to which you have referred, is desirable for lamps of very high resistance and intended to be used in parallel or multiple arc, it is no advantage for incandescent lamps of comparatively low absolute resistance, intended to be used in series; do you agree with him in this opinion? Please read Mr. Edison's answers to questions 432, 467–470 inclusive, and give your reason for any opinion you may express.

Ans. I find myself forced to disagree with Mr. Edison, in this matter as it appears to me that there can be no possible doubt that a high specific resistance is in itself desirable in any form of incandescent lamp whatever, whether the lamp be intended for working in parallel or multiple arc, or in series. As I have already pointed out, for a given current the heating effect in the lamp, other things remaining the same, is proportional to the specific resistance of the
1857 incandescing conductor. Now the total amount which is
utilized of the electrical energy furnished by the dynamo machine is that which is spent in heating the incandescent conductor, and hence, the higher the resistance of this in proportion to the resistance of the rest of the circuit, the greater will be the fractional part of the total energy which is usefully employed in heating the conductors in the lamps, and other things remaining the same, if the specific resistance is high, the same absolute resistance of the lamp may be employed although a shorter and stouter carbon is used, which is in itself a distinct advantage, as such a carbon is more easily obtained.

Int 28. In your answer to question 26 you refer to certain treatment which may be used for tempering an incandescent conductor made of carbonized fibrous or textile material; was this treatment, in both of the forms you have referred to, known in the art as applicable to carbon conductors of other kinds prior to 1880?

Ans. It was well known. I find a description of the hydrocarbon process in U. S. patent to Sawyer and Man, No. 211,262, dated Jan. 7, 1879, and a description of the tempering by heating in U. S. patent to Sawyer and Man, No. 210,809, dated Dec. 10, 1878.

Complainant's counsel offers in evidence the Sawyer and Man patent 211,262 referred to, and the same is marked "Complainant's Exhibit Sawyer and Man Hydrocarbon Treatment Patent, H. C. M., Spe. Ex."

Int. 29. Has the fibrous carbon of the patent in suit any greater susceptibility to or fitness for the processes of tempering to which you have referred, than the forms of carbon used in incandescent lamps prior to 1880?

Ans. It has, owing to the fact of its porous cellular struct-
1858 ure, which in the hydrocarbon treatment allows that material
to penetrate the conductor throughout so that the deposit of carbon thus made is not a purely superficial one, but such as to influence the entire structure of the carbon; while in the treatment by heating, the fibrous structure allows of the ready expulsion of gases from the whole interior of the filament.

Int. 30. To what extent and for what purposes have these processes been used in the manufacture of incandescent lamps since 1880?

Ans. As far as I am aware, the process of heating to a high temperature has been and is used with all incandescent lamps, while the hydrocarbon treatment has been applied to all with the exception of a very few. The hydrocarbon treatment is employed to give uniformity of resistance throughout the filament itself, and to bring the filaments of individual lamps to a given standard resistance, thus healing the defects incident to the manufacture of the filament, and allowing the employment of very many filaments which, without the use of this process, would have to be rejected, avoiding the peculiarties of the individual filaments, and causing them to approach more nearly to the condition of the ideal filament, such as would be furnished by a perfect fibrous or textile material. The extent to which the hydrocarbon treatment is carried is different with different kinds of lamps, differing with the material used by the various makers.

Int. 31. Mr. Edison, in his answer to question 54, appears to be of the opinion that when the hydrocarbon treatment is applied, the character of the carbon conductor used for such treatment is wholly immaterial, and that it makes no difference what kind of carbon is used for this purpose, or even if a metal is used. Do you agree with him in this opinion, and would such a result follow from the use of hydrocarbon treatment as applied in the commercial manufacture of incandescent lights?

1859 Objected to as being a misstatement of Mr. Edison's testimony, his opinion being expressed with reference to the experiments of Sawyer and Man, as is shown in the interference case, and not with reference to the modern practice in using the hydrocarbon treatment.

Ans. I do not agree with Mr. Edison is the opinion referred to in the question. The hydrocarbon treatment, as I understand it, is intended to remedy defects in the natural fibre, as I have already explained, but not to superede the original fibre. This is apparent from the fact that so much ingenuity has been spent in obtaining a suitable filament to begin with, although the hydrocarbon treatment was to be subsequently applied. Moreover, great care has to be taken in the original selection, and carbonization of the filaments, which otherwise fail notwithstanding that they have been subjected to treatment. As I understand the ordinary use of the hydrocarbon process, the filaments are usually treated only to a moderate or even slight extent, and not so as to destroy or render useless their original structure. That is, the original structure does not become, as Mr. Edison seems to suggest, a mere sort of scaffolding which supports the deposited carbon, but still remains an essential or indeed the essential portion of the whole conductor.

Adjourned till 2 p. m.

Resumed 2 p. m.

Int. 32. Would any of the forms of carbon of the incandescent lamps described in the prior patents and publications put in evidence by defendant, have the characteristics you have de-
1860 scribed in your answer to question 26 as possessed by the carbonized fibrous or textile material of the complainant's patent in suit?

Ans. They would not. In my opinion, there is not one of them which, even with the various improvements that have been made up to the present time, would be capable of commercial use for electric lighting.

Int. 33. Prof. Brackett states in substance, in his answer to question 5, that the construction of the bottom plate of the lamp chamber of glass, and that the dividing of the two parts by a ground joint, as shown and described in the patent in suit, was old in the art of incandescent lighting. Do you find this construction, or its equivalent, described or shown in any of the prior patents or publications put in evidence by the defendant, except the two prior patents of Sawyer and Man? Please read in this connection Prof. Brackett's answers to cross-questions 50–52, and cross-question 64; also Prof. Barker's answers to questions 10, 17 and cross-questions 58–61.

Ans. With the exception of the prior patents to Sawyer and Man, I do not find the construction in question, or an equivalent construction, in any of the prior patents or publications put in evidence by the defendant.

Prof. Brackett and Prof. Barker refer to the English patents to Staite and Kosloff, and to the United States patent to Kosloff, as embodying the particular construction set forth in the Sawyer and Man patent in suit. I fail to find any such construction in these patents.

The lamp described and figured by Staite employs a strip of metal for an incandescent conductor, which is covered by a sort of shade, presumably to screen it from the air. This shade rests upon a support, and a block of glass or some similar bad conductor of heat closes the mouth of this globe. The object of this block of glass is stated to be to aid in keeping up the temperature of the incandescent conductor. The globe covering the metal strip is filled with air at the ordinary density, there being no need of removing
1861 it, or replacing it, by an inert gas. The block of glass is not used as a stopper to prevent any perceptible ingress or egress of air, but merely serves to close the mouth of the receiver. The

Kosloff patents show a receiver containing the incandescing pencils which are inclosed in an atmosphere of nitrogen. The bottom of this receiver, however, is made tight, not by means of a glass plate or stopper, but by a hydraulic-sealed joint.

Defendant's experts also refer to Robert's British patent of 1852, but there is no description whatever of the material of which the cap closing this lamp was to be made, and from the appearance of the figure, as well as from the custom of that time, I should infer that the cap was made of metal. Defendant's experts refer to certain devices in which ground metal plates were made use of, considing these as the complete equivalent of a glass plate. I do not agree with them in this view since the coefficient of expansion of metal is so very different from that of glass that the use of a metal stopper or metal plate would unquestionably cause difficulty on this account, and the comparative rapidity with which the metal would heat or coal, as compared with glass, would be a further cause of difficulty. It seems to me that the use of the glass plate or stopper is entirely novel with Messrs. Sawyer and Man.

Int. 34. Defendant's experts have expressed the opinion that the lamp structure of the complainant's patent in suit has all the defects of the lamp structures of incandescent lamps described in the prior patents and publications in evidence; and that the lamp structure of the patent in suit would be wholly unsuitable for maintaining with sufficient stability any definite condition of the atmosphere within it, whether a vacuum or non-combustion supporting gas, to make the lamp a practically useful structure for the purpose of electrical illumination; and, moreover, that the low resistance of the incandescent conductor would make the lamp practically
1862 useless. Do you agree with them in this opinion? Please consider, in this connection, Prof. Brackett's answers to questions 12, 15, 28, and cross-questions 74–78; Prof. Barker's answers to questions 11 and 12; Mr. Edison's answer to question 61, cross-questions 306–337, questions 402–405, 476, 478, 479, cross-questions 507–515.

Ans. I do not agree with defendant's experts in the opinion which they have expressed. The lamp structure which is set forth in complainant's patent in suit employs as its conductor carbonized fibrous or textile material, which, as I have already pointed out, possesses the greatest advantages over such materials as I have mentioned before. It is true that the dimensions of the particular conductor shown in the figures of that patent are such that it would have a low absolute resistance, and hence that it would require only a low electro-motive force to furnish the somewhat strong current requisite to bring it to a proper state of incandescence. It seems to me, however, that defendant's experts are entirely in the wrong in assuming that because of these facts the structure would make "a lamp that would not be practicable." My quotation is taken from Prof. Brackett's answer to question 12. It is quite true that any lamp possessing such a low resistance would not be suited for use over considerable districts in a parallel system of illumination; but, on the other hand, it is in this respect exactly the kind of lamp that is wanted for use in a series system, and in fact lamps of low resistance and adapted to be run in series are now customarily made and employed.

So far as the other matter referred to by defendant's experts is
concerned, that is, the liability to leakage, there is no doubt that
the method devised by Sawyer and Man, like every method that
has been devised, is subject to certain imperfections; and I do not
doubt that for general use on a large scale, some other methods are
preferable, since a multitude of persons have been at work upon
this subject since 1878, and numerous improvements have
1863 been devised. But I am confident that the structure of the
lamp of complainant's patent in suit is such that, notwithstanding the fact that it is not an absolutely perfect structure, it is fitted for practical commercial use. I do not mean by this that the lamp of the Sawyer and Man patent would be able to compete commercially with gas, which appears to be Mr. Edison's test of the practical usefulness of an incandescent lamp, or that it would meet the requirements for a commercial incandescent lamp laid down by Prof. Brackett in his answers to questions 74–78. Indeed, the standard (1,000 hours) which Prof. Brackett sets up as necessary that a lamp may be "practically useful," is far above that which, as I am informed, any of the companies manufacturing incandescent lamps are at present willing to guarantee. Nor do I think that it would be able to compete commercially with more recent and improved forms of incandescent lamp, upon which a great wealth of experimentation has been lavished. But I am very confident that if we had no better styles of incandescent lamp, this would have a distinct commercial value for many purposes. And I am sure that it could be made sufficiently lasting to be of decided use. For example, I think there can be no question that a lamp of this construction could be made to last as many as fifty or one hundred hours, and such a lamp would certainly be of value for practical purposes.

I do not agree with defendant's experts that the lamp structure of complainant's patent in suit has all of the defects of the lamp structures set forth in the prior patents and publications in evidence. The use of a stopper of glass or a plate of glass, ground to the receiver as described in the patent, would very greatly diminish liability to leakage and materially prolong the life of the lamp.

Int. 35. Defendant's experts express the opinion that the in-
ventors, Sawyer and Man, made no substantial advance in the art,
or at least none that is shown and described in the patent in
1864 suit. Do you agree with them in this opinion? I call your
attention, particularly, to Prof. Bra-kett's answer to question
5, and Prof. Barker's answer to question 9.

Ans. I do not agree with Professors Brackett and Barker in regard to this. On the contrary, I find set forth for the first time in the Sawyer and Man patent in suit the use of carbonized fibrous or textile material in general, as the incandescing conductor of an electric lamp, and also of the use of such conductor in a horseshoe shape. As I have stated in answers to previous questions, I regard these as important improvements over anything that has been done before, and I am confirmed in this opinion since these are used in all modern incandescent lamps. The use of the particular form of carbon referred to, in addition to the advantages of structure and character, allows, as I have already explained, the shaping of the material prior to carbonization, which is an advantage that cannot be overestimated, and of which substantially all manufacturers of incandescent lamps have availed themselves. In fact, in this patent, Messrs. Sawyer and Man have supplied a carbon possessing those peculiar qualities which have made modern incandescent lighting a possible thing, and such carbon is actually employed in all, or nearly all, incandescent lamps which are in commercial use.

Adjourned to New York, at the office of Duncan, Curtis & Page, March 5, at 10.30 a. m.

New York, *April 5th*, 1889.

Met pursuant to adjournment.
Present: Counsel as before.

Direct examination of Prof. Cross continued as follows:

1865 Int. 36. Do you agree with the opinion expressed by defendant's experts that there is no novel or useful invention described in the first claim of complainant's patent in suit? Please read Prof. Brackett's answers to question 6 and cross-questions 37–43, and Prof. Barker's answers to question 14 and cross-questions 53–55.

Ans. I do not agree with defendant's experts in the statements referred to in the question. The first claim of the patent in suit sets forth the use of a peculiar material, namely, carbonized, fibrous or textile material, which is to be given a horseshoe shape.

The material of the incandescing conductor set forth in this claim is entirely new and not found, in my opinion, in any previous incandescent lamp; and there are, moreover, as I have already explained, advantages in the use of the arch shape with this material which do not exist with the metal conductors with which alone it had previously been employed. The form of carbon set forth in the claim, that is, carbon made by carbonizing fibrous or textile material, possesses, as I have already explained, many marked advantages over such carbon as had previously been suggested for use in incandescent lamps. Fibrous or textile material possesses the special advantage of being adapted for shaping before carbonization, a feature which is of the greatest value in the manufacture of an incandescent lamp. Moreover, as I have explained in previous answers in this deposition, there is a material advantage given to the lamp by the use in it of a conductor of horseshoe shape, in that this can adapt itself to variations of temperature which would cause a rupture of a straight filament of carbon, although with metal this is not a matter of any importance. It appears to me that the first claim of the patent in suit sets forth a distinctly new invention which did not previously exist, either in the exact form set forth in the patent in suit or in an equivalent form.

Int. 37. Do you agree with the opinion expressed by defendant's experts that there is no novel or useful invention described 1866 in the second claim of the patent in suit? Please read Professor Brackett's answers to question 8, and cross-questions 43 to 49, and Professor Barker's answers to question 16 and cross-questions 56 and 57.

Ans. I do not agree with defendant's experts in their conclusion with regard to this claim. It seems to me that they overlook the fact that there is an entirely new element which enters into the combination therein set forth; namely, that the incandescing carbon conductor is made of "carbonized fibrous material," so that the combination set forth in the claim is itself new. It does not appear to me that the lamps referred to by defendant's experts as anticipating the structure set forth in this claim really do so, for reasons that I have explained at some length in a previous answer. I know of no lamp prior to that set forth in complainant's patent in suit which contains the combination set forth in this second claim.

Int. 38. Do you agree with the opinion expressed by defendant's experts that there is no novel or useful invention described in the fourth claim of the patent in suit? Please read Professor Brackett's answers to question 9 and cross-questions 50 to 52, and Professor Barker's answers to question 17 and cross-questions 58 to 61.

Ans. I do not agree with their opinion in this matter. The fourth claim referred to is for a combination of elements one of which, the illuminating conductor made of carbonized fibrous or textile material, is entirely new, which, therefore, gives an entirely novel combination. Still more, as I have already explained at length in previous answers, the lamp structure set forth in this claim is one better adapted for preserving a stable condition of the vacuum or atmosphere of inert gas within the hermetically sealed chamber. And this last fact is of importance in its relation to the peculiar kind of carbon used for the conductor. Such fibrous carbon needed a better protection than the hard gas carbon which had previously been used as a conductor in incandescent lamps, inasmuch as it is more readily destroyed by the action of oxygen.

Adjourned to 2 p. m.

1867 2 P. M.

Met pursuant to adjournment.

Int. 39. I call your attention to the statements made by defendant's experts and Mr. Edison in regard to the extremely small proportion of fibrous vegetable materials which are suitable for making carbon filaments, and particularly to Prof. Brackett's answers to questions 16 to 18, Prof. Barker's answers to questions 22 and 23, Prof. Wilson's answers to questions 10 to 33, and Mr. Edison's answers to questions 418 to 435. What is your opinion in regard to this?

Ans. I have carefully considered the various answers referred to, and it seems to me that they all make certain assumptions which are entirely uncalled for, and without which the statements in the answers would be incorrect.

They assume in the first place that the conductor of an incandescent lamp is to be necessarily a hair-like filament, and that unless a material is particularly suited to give such a filament it is therefore quite unfitted for use as a conductor in an incandescent lamp. Now there is no assumption of this kind made by the patent, nor is it at all proper to make such an assumption, since it is by no means essential to the practical utility of such a lamp that the conductor shall be hair-like in form. On the contrary, the conductor might be of considerable magnitude without thereby impairing its value. Indeed, in certain cases a larger conductor might be highly desirable. It is unquestionably true that many vegetable materials would be fitted to produce conductors for an incandescent lamp if the assumption made by defendant's experts were removed. I am not, however, quite able to agree with them as to the difficulty in finding a material even for a fine filament which would be of material value, though it is of course true that for very fine filaments very careful selection would be necessary with respect to obtaining a material with its fibres parall- and of a dense and uniform structure.

1868 Defendant's experts, in the answers alluded to in the question, also tacitly assume that the material employed is to be used just as it comes from the muffle in which it is carbonized and without any subsequent treatment. But at the date of complainant's patent in suit there were processes of treatment well known, by means of which material which might otherwise be unsatisfactory could readily be made suitable for practical use.

Defendant's experts also assume in the answers under consideration that the material employed in the lamp of complainant's patent must be capable of competing with the best materials employed in the commercial manufacture of lamps; quite overlooking the fact that at the date of the patent it was true, as it would be true at present if great improvements had not been made in the art, a lamp would be valuable for a great number of purposes even though its life were not very long and its cost were considerable.

The complainant's patent in suit makes no such assumptions as those that are made by defendant's experts. It does not limit itself to any particular size of conductor, or to the necessary use of material fresh from carbonization and without treatment, nor does it assume a standard of excellence such as has now been reached in the development of the art of incandescent lighting. Taking it as it stands and without importing these assumptions into it, it seems to me that defendant's experts greatly exaggerate the difficulty of obtaining suitable materials for use in the lamp which it sets forth.

I am confirmed in the opinion which I have expressed in this answer with regard to the possibility of finding the various materials which may form the conductor in an incandescent lamp by the statement which I find in some of the patents which have been issued to Mr. Edison himself. Thus in United States patent No. 223,898, dated January 27th, 1880, I find the following passage:—

Int. 37. Do you agree with the opinion expressed by defendant's experts that there is no novel or useful invention described 1866 in the second claim of the patent in suit? Please read Professor Brackett's answers to question 8, and cross-questions 43 to 49, and Professor Barker's answers to question 16 and cross-questions 56 and 57.

Ans. I do not agree with defendant's experts in their conclusion with regard to this claim. It seems to me that they overlook the fact that there is an entirely new element which enters into the combination therein set forth; namely, that the incandescing carbon conductor is made of "carbonized fibrous material," so that the combination set forth in the claim is itself new. It does not appear to me that the lamps referred to by defendant's experts as anticipating the structure set forth in this claim really do so, for reasons that I have explained at some length in a previous answer. I know of no lamp prior to that set forth in complainant's patent in suit which contains the combination set forth in this second claim.

Int. 38. Do you agree with the opinion expressed by defendant's experts that there is no novel or useful invention described in the fourth claim of the patent in suit? Please read Professor Brackett's answers to question 9 and cross-questions 50 to 52, and Professor Barker's answers to question 17 and cross-questions 58 to 61.

Ans. I do not agree with their opinion in this matter. The fourth claim referred to is for a combination of elements one of which, the illuminating conductor made of carbonized fibrous or textile material, is entirely new, which, therefore, gives an entirely novel combination. Still more, as I have already explained at length in previous answers, the lamp structure set forth in this claim is one better adapted for preserving a stable condition of the vacuum or atmosphere of inert gas within the hermetically sealed chamber. And this last fact is of importance in its relation to the peculiar kind of carbon used for the conductor. Such fibrous carbon needed a better protection than the hard gas carbon which had previously been used as a conductor in incandescent lamps, inasmuch as it is more readily destroyed by the action of oxygen.

Adjourned to 2 p. m.

1867 2 P. M.

Met pursuant to adjournment.

Int. 39. I call your attention to the statements made by defendant's experts and Mr. Edison in regard to the extremely small proportion of fibrous vegetable materials which are suitable for making carbon filaments, and particularly to Prof. Brackett's answers to questions 16 to 18, Prof. Barker's answers to questions 22 and 23, Prof. Wilson's answers to questions 10 to 33, and Mr. Edison's answers to questions 118 to 135. What is your opinion in regard to this?

Ans. I have carefully considered the various answers referred to, and it seems to me that they all make certain assumptions which are entirely uncalled for, and without which the statements in the answers would be incorrect.

They assume in the first place that the conductor of an incandescent lamp is to be necessarily a hair-like filament, and that unless a material is particularly suited to give such a filament it is therefore quite unfitted for use as a conductor in an incandescent lamp. Now there is no assumption of this kind made by the patent, nor is it at all proper to make such an assumption, since it is by no means essential to the practical utility of such a lamp that the conductor shall be hair-like in form. On the contrary, the conductor might be of considerable magnitude without thereby impairing its value. Indeed, in certain cases a larger conductor might be highly desirable. It is unquestionably true that many vegetable materials would be fitted to produce conductors for an incandescent lamp if the assumption made by defendant's experts were removed. I am not, however, quite able to agree with them as to the difficulty in finding a material even for a fine filament which would be of material value, though it is of course true that for very fine filaments very careful selection would be necessary with respect to obtaining a material with its fibres parall- and of a dense and uniform structure.

Defendant's experts, in the answers alluded to in the question, also tacitly assume that the material employed is to be used just as it comes from the muffle in which it is carbonized and without any subsequent treatment. But at the date of complainant's patent in suit there were processes of treatment well known, by means of which material which might otherwise be unsatisfactory could readily be made suitable for practical use. 1868

Defendant's experts also assume in the answers under consideration that the material employed in the lamp of complainant's patent must be capable of competing with the best materials employed in the commercial manufacture of lamps; quite overlooking the fact that at the date of the patent it was true, as it would be true at present if great improvements had not been made in the art, a lamp would be valuable for a great number of purposes even though its life were not very long and its cost were considerable.

The complainant's patent in suit makes no such assumptions as those that are made by defendant's experts. It does not limit itself to any particular size of conductor, or to the necessary use of material fresh from carbonization and without treatment, nor does it assume a standard of excellence such as has now been reached in the development of the art of incandescent lighting. Taking it as it stands and without importing these assumptions into it, it seems to me that defendant's experts greatly exaggerate the difficulty of obtaining suitable materials for use in the lamp which it sets forth.

I am confirmed in the opinion which I have expressed in this answer with regard to the possibility of finding the various materials which may form the conductor in an incandescent lamp by the statement which I find in some of the patents which have been issued to Mr. Edison himself. Thus in United States patent No. 223,898, dated January 27th, 1880, I find the following passage:—

"I have carbonized and used cotton and linen thread, wood splints, papers coiled in various ways," etc.

Also, in his patent No. 238,868, dated March 15th, 1881, Mr. Edison says, after referring to the peculiar characteristics
1869 necessary for the carbon of the conductor in an incandescent
lamp, that "simple wood carbon of unchanged structural condition possesses these qualities." In the same patent he describes the production of such a carbon for a conductor from "a block of wood." In the same patent he claims a method of forming carbons which he says consists "in shaping a block of wood as described," and subsequently shaping and carbonizing it.

Also in United States patent, No. 248,417, dated Oct. 18, 1881, Mr. Edison uses carbons made from "a block of wood taken and cut in a machine or lathe." He then proceeds to describe the particular way in which such a block of wood is to be split and carbonized, and shows in his figures such a block of wood; also, in the claim of this patent he sets forth a method of forming the carbons "consisting in cutting or turning a block of wood," etc.

And again in United States patent No. 251,540, dated December 27th, 1881, Mr. Edison, referring to what he designates as a "filament of carbon bent into a curve now generally designated the 'horseshoe' carbon," says, "Great success has attended the use of such carbons made from a natural fibrous material capable of carbonization—for instance, wood formed into proper shape and then carbonized."

Int. 40. Were the peculiarities of structure of exogenous and endogenous plants and the other vegetable growths referred to by defendant's experts, and the effects of such structure upon the character of the carbon resulting from carbonizing them, known prior to the filing of the applications for the patent in suit?

Ans. They were. All of the matters referred to as to the structure of plants have been perfectly well known, not merely to botanists, but those who like myself are not skilled in that science. Also the methods of carbonization of such structures and the effect produced upon them by the process of carbonization were perfectly
1870 well understood. It was well known that certain woods were
fitted, and certain others unfitted, to produce a carbon of even and dense structure, and the state of knowledge was such that one skilled in the art would have known that certain woods must be rejected and that certain others would be better fitted for his purpose. The desirability of avoiding a cutting across the fibre and of selecting a wood possessing fibres which were parallel, would certainly have been recognized by one skilled in the art and wishing to practice the invention set forth in complainant's patent in suit.

Int. 41. Were the general peculiarities of structure of the bamboo in regard to which Professor Wilson testifies, generally known prior to the filing of the application for the patent in suit?

A. They were well known at the date mentioned. It seems to me that at the date of the patent in suit a person who was searching for a suitable woody fibre to use in an incandescent lamp would very naturally have picked out bamboo fibres for his purpose.

Int. 42. I notice that defendant's experts have very little if anything to say in regard to textile materials; what is your opinion in regard to the suitability of materials of this general class for making conductors for incandescent lamps?

Ans. I should say that they were pre-eminently suitable for this purpose. They already existed in such a shape that, when carbonized, they may be used in an incandescent lamp, and I think my opinion is justified from the fact that such materials are widely used in the manufacture of incandescent lamps.

Int. 43. What do you understand to be meant by textile materials, and what are the most common materials, of this class in the market?

Ans. Defendant's expert, Professor Brackett, gives a very clear definition of textile material in his answer to question 2 of his second deposition in this suit. The definition of textile material 1871 there given is that it is a material suited to be spun or woven. Thread is of course a material of this kind. The most common materials of this class in the market are cotton and linen thread, silk and hemp.

Adjourned to April 6th, 11 o'clock.

NEW YORK, *April* 6, 1889.

Met pursuant to adjournment. Present, counsel as before, and the examination of Prof. CROSS was continued as follows:

Complainant's counsel offers in evidence Patent Office copies of U. S. patents granted to T. A. Edison, No. 238,868, dated March 15, 1881, and No. 248,417, dated October 18, 1881, and the same are marked respectively, Complainant's Exhibit Edison Patent No. 238,868, and Complainant's Exhibit Edison Patent No. 248,417, both of April 6, 1889.

Int. 44. Do you agree with the opinion expressed by defendant's experts that there is not a sufficient description in the specification of the patent in suit as to the character of the fibrous material to be used for the burner, its selection, its preparation for carbonization, and its carbonization, to enable others generally skilled in the art as it existed at the date of the application, viz.: January 9, 1880, to produce a practically operative incandescent conductor without experiment? Please read Prof. Brackett's answers to questions 16 and 19, inclusive, cross-questions 55 to 63 inclusive; also Prof. Barker's answers to questions 22 to 27 inclusive, and cross-questions 66 to 85 inclusive; also Mr. Edison's answers to questions 418 to 429 inclusive, 433 to 435, inclusive, 439 to 441 inclusive, 449 to 464½ 1872 inclusive, and give your reasons for any opinions that you may express. I also call your attention to Mr. Edison's answers to questions 25 and 26.

Ans. I do not agree with defendant's experts in their opinion that the Sawyer and Man patent in suit is defective in the matter referred to in the question. The patentees direct the use of carbonized fibrous or textile material and state that they have used carbonized paper and also wood carbon. With regard to the use of the first of the materials mentioned, I think there is no possible question that one wishing to make use of the invention described in the Sawyer and Man patent would have known how to proceed in order to procure a paper suitable for his purposes. He would naturally have assumed that a pure paper was desirable, and so would have rejected papers which were loaded with mineral matter or with size and similar materials. He would also have sought a paper of even texture. I am confident that at the date *at* the application for the patent in suit and for many years before as well as since pure paper could readily be procured in the market. For example, bristol-board is a kind of paper that was well known to be pure in quality and even in texture and which, I think, one would naturally have selected for the purpose. Blotting paper is another well-known variety which could be obtained in a state of purity. Still more, there were various processes by the use of which the adulterants employed in the manufacture of paper could have been removed, had such paper been employed. As a matter of fact, paper has been largely and successfully employed in the manufacture of incandescent lamps. Thus Mr. Edison, in that portion of his deposition referred to in the question, describes his own employment of that material. Also, some of the types of lamp manufactured by the United States Electric Lighting Company have been made of paper and have been very widely used and with satisfactory results.

With regard to wood carbon, it seems to me that the directions in the patent are quite sufficient to have enabled one to utilize
1873 this in a lamp of commercial value. I think that one reading the Sawyer and Man patent would have understood the term "wood" in the sense in which it is defined by Prof. Barker in his answer to question 22 as referring to

"The material which constitutes the stems of most, if not all, vegetable substances."

With this understanding he would doubtless have selected from among the various well-known forms of woody tissue those in which the fibres were parallel, long and even. He certainly would not have limited himself to exogenous growths, but would have included in his range the various endogenous plants. Also, he would probably have picked out a thread of cotton or other material of even texture and pure quality.

Having selected the material it would be neessary to determine upon its shape. There is no question that in the use of textile material the shape would be determined prior to carbonization. Indeed, the very nature of such material in general necessitates this and unquestionably implies it. If paper were the material selected I cannot imagine that any one would fail to see the desirability and practical necessity of shaping it before it was carbonized. It is already shaped in one dimension and would naturally be cut or stamped into shape while the paper was still uncarbonized and easily cut. This mode of procedure is infallibly suggested by the statements of the patent.

As to the carbonization, the patent gives no especial description, but contents itself with referring to the various well-known processes of carbonization. And it does this very properly, since the subject of carbonization had been carefully studied and the methods whereby thorough, uniform and complete carbonization could be secured were perfectly well known to those skilled in the art.

It is, of course, true that in one desirous of practicing the invention under consideration an exercise of common sense, good judgment and technical information would be necessary in order
1874 to exclude unsuitable and select suitable materials for the
purpose, and undoubtedly experience would show one that certain of the various materials selected were much better adapted to the purpose than others; but, in my opinion, all this would involve simply the ordinary skill of the artizan and not the ingenuity of the inventor.

The same remark applies to the subsequent process, as of carbonization.

I think there can — no possible question that one familiar with the state of the art at the date of the application for the Sawyer and Man patent in suit, by the exercise of existing knowledge, employing only the skill of the trained artizan and without invention, would have been able to construct an incandescent lamp which would serve a useful purpose and have a commercial value.

Int. 45. Would it, in your opinion, have required experiment on the part of a person skilled in the art as it stood prior to 1880, to reach the conclusion expressed by Prof. Barker in his answer to question 27 that a carbon conductor made from a strip cut across the grain or fibre of wood would be useless for incandescent lighting?

Ans. In my opinion, it would not.

Int. 46. Would it have required experiment to ascertain the defects stated by Prof. Barker in his answer to question 25, of carbon formed by cutting blanks of arch form from wood in such a manner that the fibres were cut across in a part of the length of the conductor?

Ans. It would not. This fact was perfectly well known.

Int. 47. Do you think any person skilled in the art as it stood prior to 1880 would have attempted to make carbons in that way if he were merely told to use carbonized fibrous or textile material for the conductor of a lamp?

Ans. I should not think it possible that he would have done this. Such a procedure is not at all that which is suggested by the direction.

Int. 48. What would such a person have known to be
1875 requisite with respect to uniformity of resistence in the
conductor of an incandescent lamp, and what would this, in your opinion, have necessarily implied to such a person in the selection and preparation of the material before carbonization?

Ans. He would have known that the resistence of the conductor should be as nearly as possible uniform throughout. This would have led him to select fibrous material or fibers which were continuous, and which would not be cut or broken in shaping.

Int. 49. If such a person desired to make a conductor in an arch form from carbonized wood, what would, in your opinion, have been the method of making it which would most readily have occurred to him with no further instructions than those stated in question 47?

Ans. It seems to me that it would naturally have occurred to him to make use of the long fibers of some of the different varieties of grass or reeds or perhaps the woody leaves of some plants, or probably some fibrous bark. I think he would have selected such a fibre, bent it into shape and keeping it in that condition would have subjected it to thorough carbonization.

Int. 50. Do you think that a person skilled in the art as it stood prior
to 1880, and desiring to succeed in producing a very slender
1876 filament from carbonized fibrous or textile material would
select wood having interlaced fibres and thereby encounter
the difficulties referred to by Prof. Wilson in his answers to questions 19 to 23, inclusive?

Ans. Certainly not. That would be the precise way not to do it.

Int. 51. Do you think he would select wood so resinous as to produce the defects referred to by Prof. Wilson in his answer to question 24?

Ans. I cannot imagine that he would do this.

Int. 52. Do you think he would select vegetable tissues merely because they could be readily cut, although they would be practically worthless for electrical purposes or merely because the wood in itself was tough before carbonization, as is apparently assumed by Prof. Wilson in his answer to question 25?

Ans. Certainly he would not do this.

Int. 53. In your answer to question 39 you say that the defendant's experts assume that the conductor of an incandescent electric lamp is to be necessarily a hair-like filament, and that you find no such assumption in the patent in suit. Would there be less difficulty in selecting proper fibrous or textile material for making thicker conductors, as, for instance, conductors approaching the thickness of that shown in the drawing of the patent in suit, than in selecting proper material for hair-like filaments?

Ans. There would, unquestionably. Many substances
1877 which would not furnish fine hair-like filaments of the qual-
ity necessary for use in an incandescent lamp would be
amply sufficient if the conductor was to be heavier.

Int. 54. What is the reason for this?

Ans. There are many vegetable substances which cannot readily be split into very fine filaments or which if so split are too brittle to give satisfaction, which will nevertheless furnish filaments of large section.

Int. 55. In your answer referred to you also say that there were processes of treatment well known by means of which material which might otherwise be unsatisfactory could readily be made suitable for practical use. To what processes did you refer?

Ans. I had in mind that consolidation of the carbon which occurs when occluded gasses are driven from it on raising it to a high state of incandescence by carrying a heavy current through it and especially the beautiful process of hydrocarbon treatment, which was also devised by Messrs. Sawyer and Man. In this latter process the filament is carried to incandescence by passing a heavy current through it while surrounded by an atmosphere of hydrocarbon vapor. The vapor is decomposed and carbon deposited most 1878 abundantly wherever the heating is greatest. And as such heating is necessarily most pronounced at those points in the lamp which are defective, carbon is most abundantly deposited at these points, thus healing the faulty places in the lamp. This process is so valuable that it is employed with most types of lamps of to-day.

Int. 56. Are these the processes to which you refer in your answers to questions 26 to 28?

Ans. They are.

Int. 57. Would the use of these processes materially increase the proportion of fibrous and textile materials which would be available for making practically useful incandescent conductors for electric lamps?

Ans. They would very greatly increase the number of such materials.

Int. 58. In selecting endogenous stems do you think that a person skilled in the art, as it stood prior to 1880, would select material which would produce the undesirable results set forth in Prof. Wilson's answer to question 28?

Ans. On the contrary, I should suppose that he would endeavor as far as possible to avoid the use of endogenous material in which these characteristics are prominent.

Int. 59. When translated into common language what is the substantial meaning of Prof. Wilson's disquisition on the structure of the bamboo stem contained in his answers to questions 29 to 32 inclusive?

Ans. As I understand Prof. Wilson's statements referred to, the structure of bamboo is identical in its nature with that of other endogenous plants, but that a certain kind of tissue, the bast cells, are so compacted and joined together as to give a very homogeneous filament which particularly fits it for use in an incandescent lamp.

Int. 60. Is there any other peculiarity of bamboo which makes it peculiarly suitable for making very slender filaments?

Ans. Of course its fibrous structure as a whole particularly fits it for this purpose and the special portion of the stem referred 1879 to by Prof. Wilson presents these characteristics in a very marked degree.

Int. 61. Were these peculiarities of bamboo known prior to 1880?

Ans. They were, all of them, as I understand the matter. Certainly its fibrous character and the facility with which it could be split into fine uniform fibres had been known for an indefinite period.

Int. 62. Defendant's experts express the opinion that the amendments made in the application for complainant's patent in suit materially changed the scope or nature of the invention which was described and claimed. Please compare the specification and claims of the patent as issued with the specification and claims as originally filed and state whether or not you find any invention described and claimed in the patent as issued which was not described in the application as originally filed.

Ans. Considering the patent as issued, I find that claim 1 sets forth: "Carbonized fibrous or textile material" as the material of the incandescent conductor and the "arch or horseshoe shape" as its form. The 4th claim of the specification as filed sets forth the use of carbonized fibrous or textile material as the material of the conductor and the horseshoe shape is fully described in the original specification in which the patentees speak of the "arch-shaped" carbon used.

The second claim of the patent as finally issued relates to the use of "an incandescing conductor of carbonized fibrous material," without reference to its shape, and enclosed in a transparent hermetically sealed chamber. The carbonized fibrous material of this claim is evidently referred to in the fourth claim of the specification as originally filed, and as I understand that in the fourth claim the shape of the incandescing conductor is not limited, I judge that the word "arc" used therein means simply strip. The specification as originally filed specifies the use of the incandescent carbon in
1880 transparent chambers. The specification also says that the patentees have used carbonized paper and wood carbon or charcoal.

The third claim of the patent as issued is for an incandescing conductor of carbonized paper. Besides the reference in the original specification to the use of the carbonized paper, to which I have already referred, the third claim of that specification relates to the use of carbonized paper.

The fourth claim of the patent as issued relates to the combination of the chamber "made wholly of glass" and containing no carbon-consuming gas, and other elements in combination with an arch-shaped incandescing conductor consisting of "carbon made from a fibrous or textile material." In the specification as originally filed the patentees after referring to their "burners" of carbonized paper, wood, carbon, etc., and of an arch-shaped form, among others, go on to say that they have used such burners "in close transparent chambers" *in vacuo*, in nitrogen, etc., and state that the important thing in this regard is to exclude oxygen. Also they state that their invention is an improvement upon the apparatus shown in their earlier United States patent (No. 205,144) which shows a carbon pencil enclosed within a hermetically sealed chamber made wholly of glass. I do not find any invention whatever described and claimed in the patent as issued which was not described in the original application.

Int. 63. Defendant's experts refer to the omission from the final specification of the words "ordinary gas carbon," which appear in the specification as originally filed. Does the omission of these words, in your opinion, expand or narrow the scope of the patent?

Ans. I should say that they narrowed it.

Int. 64. Defendant's experts also refer to the omission from the final specification of the word "charcoal," which appears in the specification as originally filed. Please read Prof. Brackett's answer to question 21, and Prof. Barker's answers to questions 30 to 32, inclusive, and state whether you agree with the opinions there
1881 expressed, and what your opinion is in regard to the effect of
the change referred to?

Ans. I do not agree with defendant's experts that the dropping of the word "charcoal," either designedly or in fact, alters or broadens the patent. As I have already shown in previous answers in this deposition, the word "charcoal" is very ambiguous. It might have been taken to mean gas carbon, or else the substance popularly known and sold as charcoal, neither of which meanings, as I understand it, was intended by the patentees. That is, the word as it stood was a misleading one, and calculated to obscure the specification, and was therefore dropped.

Int. 65. Taking any meaning of the word "charcoal," either as used in the arts or popularly, did the omission of this word, in your opinion, in any way broaden the scope of the patent?

Ans. I do not see how it is possible that the omission of the word "charcoal" in any sense in which it could be understood, can in any way broaden the patent.

Int. 66. Defendant's experts also refer to the omission from the final specification of the words "covered with powdered plumbago" used in the original specification in connection with the words "carbonized paper." Do you agree with them in the opinion they express in regard to the effect of this change? Please read Prof. Brackett's answers to questions 22 and 23 and Prof. Barker's answer to question 37, and give your reasons for any opinion that you may express.

Ans. I do not agree with them. The original specification sets forth the use of carbonized paper, which is no less paper because it has been covered with plumbago. Such treatment with plumbago certainly was not essential and was not intimated as being essential in the original specification, nor would any one have had reason to assume from that specification that it was essential. Whether the paper was or was not covered with plumbago, it was equally susceptible to shaping before carbonization and likewise possessed
1882 the valuable properties characteristic of fibrous carbon for
the conductor of an incandescent lamp. It seems to me that the expression, which is vague and indefinite, and hence obscure, was for this reason omitted from the final specification.

Int. 67. Do you find anything in the expression "carbonized paper covered with powdered plumbago," or in any other language used in the original specification that would in any way suggest to a person skilled in the art that the method of carbonization by passing an electrical current through a piece of paper impregnated with powdered plumbago referred to in question 23 to Prof. Brackett, and in Prof. Barker's answer to question 37 was to be used?

Ans. There is absolutely nothing in that specification which could possibly convey the remotest suggestion to this effect.

Int. 68. Is it true as stated in the final specification that methods of carbonizing material while confined in retorts in powdered carbon were in practice before the filing of the application for the patent in suit?

Ans. It is true.

Int. 69. Was this method well known and had it been used in the art of electric lighting prior to the filing of the application for the patent in suit?

Ans. It was well known and had been so used.

Int. 70. Defendant's experts also refer to the fact that the expressions "composed wholly of glass," "that the entire wall of the chamber is formed of glass;" and "another important advantage resulting from our construction of the lamp results from the fact that the wall forming the chamber of the lamp through which the electrodes pass to the interior of the lamp is made wholly of glass by which all danger of oxidation, leakage or short circuiting is avoided," appear in the final specification, but that in the original application no such specific description is given of the lamp chamber. Please read Prof. Brackett's answers to questions 25 to 28 inclusive and Prof. Barker's answer to question 38 and state 1883 whether or not you agree with the opinions there expressed in regard to the effect upon the scope of the patent of these changes in the specification.

Ans. The specification as originally filed refers back to their earlier patent, No. 205,144, which unequivocally describes the construction under consideration. In that patent there is a minute description of the construction referred to in your question and also a specific statement that a ground-glass stopper may be used through which the leading wires of the lamp may enter. Under these circumstances I disagree from Messrs. Brackett and Barker with regard to the subject referred to in your question.

Int. 71. Is the language referred to in my previous question appropriate for describing the actual construction shown in the drawing of the patent in suit and described in the prior patent of Sawyer and Man referred to in the original application for the patent in suit?

Ans. It is perfectly appropriate to describe that construction.

Int. 72. Defendant's experts also refer to the statement contained in the final specification that "the sealing of the electrodes where they pass through the glass wall is done with any suitable cement or in any of the well-known methods of sealing glass upon metal electrodes previous to the filing of this application does not occur in the application as originally filed. Please read Prof. Brackett's answer to question 29 and *and* Prof. Barker's answer to question 39, and state whether or not you agree with the opinions there expressed as to the effect of this change.

Ans. I do not agree with Professors Brackett and Barker in the opinions which they express regarding this matter. Even without any specific statement it would of course be understood that one was at liberty to use any of the well-known methods of hermetically sealing the leading-in wires into the glass. The mode of doing this commonly employed at present has been known for a great 1884 many years in the manufacture of Geissler tubes and similar apparatus and was well known long prior to the date of Sawyer and Man's first patent.

Int. 73. Defendant's experts also refer to the fact that the statement contained in the final specification in regard to the advantage of the arch form in providing for the expansion and contraction of the carbon does not appear in the specification as originally filed. Please read Prof. Brackett's answers to questions 33 to 37 inclusive and Prof. Barker's answer to question 43, and state whether or not you agree with them as to the effect of this change in the specification.

Ans. I do not agree with Professors Brackett and Barker in this matter. On the contrary, it seems to me that the arch-shaped carbon as shown in the drawings of the patent in suit would possess that greater stability and adaptability to changes in temperature which are set forth in the specification, so that it would be much less liable to fracture. Inasmuch as this arch-shaped conductor was fully described and set forth in the original specification, I fail to see that the scope of that specification is enlarged merely by a fuller statement of its advantages.

Int. 74. Do you find anything in the application as originally filed which would suggest to a person skilled in the art as it stood prior to 1880, that in making carbon conductors from fibrous or textile material, such material was to be shaped to any extent before carbonization?

Ans. In the specification the patentees state that they have tried carbonized paper, which, from its very structure, is necessarily shaped in one dimension before carbonization and which would naturally have been shaped in all dimensions before carbonization as well. There is also a further reference to carbonized paper in the third claim. Still further, the fourth claim refers to the use of carbonized textile material as well as fibrous material and this would necessarily have its shape determined prior to carbonization. The fact that the textile material is to be carbonized would 1885 of itself indicate that such material was started with in an uncarbonized state and evidently its form would be there to begin with and could not be impressed upon it subsequent to carbonization. It seems to me that shaping prior to carbonization is necessarily implied in these references.

Int. 75. Do you agree with defendant's experts in the opinions they express on this point? Please read Prof. Brackett's answer to question 32 and Prof. Barker's answers to questions 41 and 42.

Ans. I do not. It seems to me that a person who started to employ paper as the material for the incandescing conductor of the lamp would inevitably begin by picking out a paper of what he judged to be a suitable thickness. And I do not doubt that he would also cut from that paper a strip of what he judged to be a proper size and then proceed to carbonize it. I cannot imagine that a person would be so stupid as blindly to take a piece of paper at random, carbonize it and then after it was all carbonized go to work for the first time to fix its dimensions, rubbing down its surface by filing or cutting it away. And if for any reason a person wished to use a strip of greater thickness than would be given by a single layer of such paper as he had chosen, I think there can be no reasonable doubt that he would have placed the layers of paper upon one another prior to carbonization rather than subsequently.

Int. 76. Do you think that a person skilled in the art as it stood prior to 1880, would have adopted any other or different method of making conductors from carbonized fibrous or textile material in following the specification of the patent as issued from that which he would have adopted from following the specification and claims as originally filed?

Ans. I do not.

Int. 77. When do the greater part of the changes in the original specification to which defendant's experts refer to have been made?

1886 Ans. They appear to have been made by the amendment dated May 17, 1880.

Objected to as a misstatement of what is shown by the record offered in evidence by complainant.

Int. 78. Prof. Barker appears to express the opinion in his answer to question 42 that in the original application as filed, the patentees did not express any preference for carbonized fibrous or textile material over the other forms of carbon mentioned in that specification. Do you agree with him in this opinion?

Ans. I do not. Carbonized paper and wood carbon are the first kinds of carbon which they mention in their statement of what they have used, gas carbon being mentioned subsequently to these. In the third claim the use of carbonized paper is set forth and in the forth claim an incandescing conductor made of carbonized fibrous or textile material is set forth. There is only a single specific reference in the whole patent to any kind of carbon other than fibrous carbon, and that is a simple statement that gas carbon has been tried. The only kind of carbon specifically referred to in the claims is fibrous carbon.

Int. 79. Do you agree with the opinion expressed by Prof. Barker in his answer to question 50?

Ans. I do not. The Gaudoin patent describes a process of making carbon pencils for use in electric lighting, which term at the date of the original patent was used only as referring to arc lighting, although later Gaudoin's carbons were used experimentally in some arc incandescent light. The whole process which Gaudoin describes is adapted and professes to be adapted to produce a hard and compact carbon precisely such as was suited for arc lighting carbons and not at all that which is adapted for incandescent lighting. That is, the pitch, resin and bitumen used in the original patent or the wooden object impregnated with these or other

1887 similar materials which are referred to in the certificate of addition are totally different things from the fibrous carbon set forth in complainant's patent in suit. The aim of the Gaudoin patent was to make pencils possessing the characteristics of pencils of gas carbon, an end which other inventors prior to Gaudoin had also sought to obtain. It seems to me that there is nothing in the Gaudoin patent which would in any way guide a person to use such carbon as he is taught to use by complainant's patent in suit.

Prof. Barker is incorrect in his statement that the Gaudoin pencils "not over a millimetre or two in diameter" were "adapted only to the production of light by incandescence" They were adapted to be used, and in fact, were used in arc incandescent lamps. It would of course have been possible to use them instead of gas-carbon pencils in such an incandescent lamp as that shown in Jensen's British patent No. 970 of 1875, but if they were to be so used they would possess no properties superior to or different from those of the hard gas-carbon pencils made for the same purpose.

Int. 81. Do you agree with the opinion expressed by Prof. Brackett in his answers to redirect questions 119 and 120, that there would be no difference in the relative value for electric lighting purposes between the lamp described in the patent in suit, and that of the prior patent of Roberts, Shepard, Konn, Koslorff and others to which he has referred, as anticipating the claims of the patent in suit?

Ans. I do not. It seems to me that the lamp of the patent in suit would possess a value much greater than that of any of the prior lamps.

Adjourned to meet at the Hotel Brunswick, Boston, Mass., Monday, April 8, at 9 a. m.

1888 Cross-examination of Prof. Cross by Mr. Dyer:

82 X Q. You stated in answer to question 2, that you had published a number of papers on the telephone and electric lighting. Please state where those relating to electric lighting can be found.

A. There is one paper on the inverse electro-motive force of the voltaic arc, published in the proceedings of the American Academy of Arts and Sciences, which was the particular paper relating to electric lighting which I had in mind in my reply to the question. I also published a paper a few years ago on an allied subject, namely, the melting platinum standard of light. I have also been a member of committees which have reported on electric lighting devices. I should have to hunt up the matter to see what portions of these reports have actually been written by myself. I do not recall any other papers relating to electric lighting besides these, though there are several which are at present waiting for publication as soon as I can get them into shape.

83 X Q. What is the principal source of light in all three kinds of electric lamp that you have referred to employing carbon for the burner?

A. In the electric arc, as I have already said, most of the light comes from the terminals of the pencils, which become white hot in virtue of the action which goes on there. In the arc incandescent light, the light emitted comes from the intense heating of the carbon at the joint made between the two conductors. In the incandescent lamp, the light comes from the intense heating of the whole carbon strip through which the current is passed. There is only one thing which is common to all three, and that is, that it is white-hot carbon which radiates the light. The laws governing the production of this light, and the various circumstances which influence its peculiarities, are vastly different in these different kinds of lamps.

84 X Q. Then the fact is, that in all three kinds of
1889 electric lamps, the light is produced by the incandescence of
the carbon?

A. It is, if you see fit to use carbon in all three forms. Of course substances other than carbon can be used for every one of these three lights.

85 X Q. Is there not also another source of light in the arc lamp?

A. There is the hot space between the two carbons emits a certain amount of light, being filled with various vapors and with matter coming from the hard carbon employed for the electrodes. The light from this space is objectionable rather than the opposite. I suppose also there is a little light which comes from the combustion of the carbon pencils employed; but if these are of hard carbon, this combustion is trifling.

86 X Q. Does this luminous space exist in the arc incandescent or semi-incandescent lamps?

A. I do not suppose that this space is present in what may be called the normal operation of that lamp. I think, however, that as the carbon wears away, minute arcs are probably formed. The theory of the operation of this lamp is in some respects a little obscure, since certain phenomena characteristic of such a joint come into play, that have not been very fully investigated.

87 X Q. The semi-incandescent lamp, then, differs from the arc lamp in the respect that in its normal operation the light is wholly produced by the incandescence of the carbon?

A. Yes, I suppose that is so, if the lamp ever operates normally, which I question. There is never any visible gap between the electrodes in the arc incandescent lamp, if that is what is meant by the question. These lamps have proved so useless in practice that they have not been studied very carefully, and although at one time they were looked upon as likely to be useful, they appear to have been set aside, so that their theory has not been studied as minutely as that of the arc or incandescent light.

88 X Q. Is it not a fact that in arc lamps the luminous
1890 space being depended upon to produce the effect, electrodes
of relative large diameter can be employed, while in the arc
incandescent lamp a relatively small carbon or pencil is necessary,
in order to produce the necessary resistance?

A. I do not think I understand the question; that is, I do not feel sure what "the effect" alluded to is. Certainly the luminous space does not produce the illuminating effect of the arc light, if that is what is meant. On the contrary, the luminous rays coming from this space are objectionable, if they are sufficiently abundant to be noticeable, and in some forms of lamp an endeavor is made to get rid of them. It is true that larger carbon pencils are usually employed with the arc light than with the arc incandescent light, but this is in order to confine the heating effect to the ends of the electrodes and to prevent the burning away of the electrodes for a considerable distance away from the air space. Also, it is highly desirable that the carbon pencils should be of large section in order that they may interpose as little resistance as possible to the passage of the current through them. One of the carbons of the arc incandescent lamp is usually brought down to a fine point, in order to localize the heating effect. But the other electrode is usually larger, and sometimes very large indeed.

89 X Q. It is the incandescence of the small-pointed carbon which produces the light, is it not?

A. I suppose that the light comes principally from this, though as I have already said, the phenomena attending the operation of this lamp are somewhat obscure.

90 X Q. How large in diameter are the smaller-pointed carbons of the arc incandescent lamp?

A. I have never seen such a lamp, as constructed by any manufacturer; but I suppose the diameter is somewhere between $\frac{1}{20}$ and $\frac{1}{10}$ of an inch. I once tried to make an experimental lamp of this character, and used a carbon of about the larger size mentioned, such as I happened to have. I brought its end down to a sharp point.

1891 91 X Q. How far back from the extreme point does the incandescence extend in these arc incandescent lamps?

A. As I understand it, only a short distance back. That is, the intention, I think, is rather to get the intensely bright light (which resembles in some of its characteristics that of the voltaic arc), from the point in which the two electrodes meet. In such experiments as I have made, the light did come from this point, and but little from that portion of the carbon which is beyond it. I have said that the operation of this lamp, and consequently the precise way in which its light is generated, is a little obscure. I have a notion that certain phenomena of repulsion which come into play when a current passes from one electrode to another, may operate here, and that some operation of this kind gives rise to an arc-like character at the joint of contact.

92 X Q. Is that repulsion sufficient to overcome the weights or springs that are used to maintain the electrodes in contact in these lamps?

A. Under certain circumstances, it might be. I cannot say that it is in all.

93 X Q. Do you know that it is in any?

A. I am confident that it was in the experimental lamp to which I refer, and I feel quite certain that it would be sufficient in some others, of which I have seen drawings. I do not wish it understood that I have any fully developed theory on the subject, but merely that the action which I had in mind, seemed to me to aid in the explanation of certain phenomena. I should want to investigate the matter with care before adopting any very positive opinion.

94 X Q. Please state what the construction of the experimental lamp you refer to, was.

A. I do not recollect minutely, but there was a light pencil of carbon which rested on a block of carbon, the current passing from one to the other. In another case, I remember carrying the current from a carbon electrode attached to a spring to another,
1892 on which it rested lightly; this last action happened accidentally in connection with some other experiments.

95 X Q. Is it not a fact that the extent of the incandescence of the pencil of the arc incandescent lamp will depend largely upon the size of that pencil; and if it is made small enough, the incandescent portion will extend back a considerable distance?

A. I suppose that it is true of the arc incandescent lamp, as it is also true of the arc lamp, in which with small carbons these become incandescent to a greater distance from the air space between them, the heat being conducted from the focus along the carbons. I suppose the same thing is true with the arc incandescent light, that is, the heating effect is particularly intense at the contact point of the two electrodes, and will spread from this focus to a greater distance along the electrodes if these are smaller. I should think, however, that in both cases it would be damaging to carry this effect to any considerable extent, and that it would be likely to render the arc incandescent lamp inoperative.

96 X Q. Would it still be an arc incandescent lamp, if the pencil were small enough to be heated to incandescence to a material extent back of the point?

A. I do not understand the force of the term "material."

97 X Q. What feature in the construction of an electric lamp makes it an arc incandescent lamp, and not an arc lamp?

A. The term arc incandescent lamp has been applied to lamps in which a pencil of carbon rests upon a second piece of carbon, so that there is a less intimate contact among the particles at this joint than among the particles of either carbon.

98 X Q. If the pencil of carbon of the same diameter throughout its length rests, end on, upon a block of carbon or upon a block of metal, say faced with platinum or iridium, and light be
1893 produced by passing an electric current through the point of contact or joint, would the light be of the arc incandescent character?

A. I should say that if the light were produced by the passing of the electric current through the joint, and by that only, or substantially by that only, the light would be of the arc incandescent character. I don't know what the effect of any metal might be, as I recall only the use of carbon in lamps of this character.

99 X Q. Would not the construction first assumed in my last question, namely, a pencil of carbon of the same diameter throughout its length, resting, end on, on a block of carbon, be one in which

there is a less intimate contact among the particles at this joint, than among the particles of either carbon?

A. It would.

100 X Q. Would a weight, or spring pressing the parts together, change the relative intimacy of the particles at the joint and in the body of the pencil to such an extent as to deprive the lamp of its arc incandescent character?

A. I do not see that such a weight or spring would produce any material change in the intimacy of contact of the particles in the body of the pencil. The effect which would be produced at the joint would depend altogether upon the magnitude of the force employed. I suppose that if a sufficiently strong pressure were used, an arc incandescent lamp might be rendered inoperative by excessive reduction of the resistance at the joint. But under these circumstances it would cease to operate as a lamp.

101 X Q. What would be the effect of increasing the current in such a lamp, so as to make the carbon incandescent?

A. What I suppose you really desire me to state is to what class of lamps your device properly belongs, if it were capable of being made operative under the conditions which you imagine. I should think that under these circumstances it would properly be classified as an incandescent lamp.

1894 102 X Q. Would not the pressure which you have assumed as sufficient to suppress the arc incandescent action at the joint, bend or buckle the carbon pencil if raised to a light-giving incandescence by the increase of the current?

A. The matter regarding which you are questioning me is purely hypothetical in its nature, so that I cannot speak as confidently as I would like to do. I think it would be possible to get up such an experiment substantially as you suggest, in which the incandescence was substantially from the carbon as a whole, and not from the joint in particular, without buckling the carbon to such an extent as to prevent the trial of the experiment. I do not believe that a commercial electric incandescent lamp could be made in this way.

103 X Q. For an operative incandescent lamp, it is essential, is it not, that a better connection should be made with the end of the carbon pencil than would be formed by pressing a pencil of the same diameter throughout its length, end on, on a carbon block by means of a weight?

A. I should not choose such a method of connection, but I should think that a lamp of this kind could undoubtedly be made to operate, notwithstanding the use of such a connection.

104 X Q. The carbon pencil would be hotter at the joint, would it not?

A. I don't know. I suppose that the greater resistance there would make it somewhat hotter, but the great heat of the other portions of the pencil would, I should think, prevent any large difference from existing. I never saw a lamp of this kind.

105 X Q. Then, as I take it, if you were shown the drawing of an electric lamp having a carbon pencil resting on a block of carbon, and pressed down by a weight, you could not say whether it was an

arc incandescent or an incandescent lamp, unless you knew how heavy the weight was intended to be?

A. That would depend entirely upon the drawing.

1895 106 X Q. What features of the drawing would guide you?

A. I suppose that if it were a device unlike any that I recognized, the size and arrangement of the pencil and the general aspect of the device would guide me in coming to whatever opinion I reached. It is very likely that a drawing might not of itself be sufficient to indicate the precise character of the apparatus.

107 X Q. In view of the well-known fact that it is necessary in incandescent lamps to securely clamp the ends of the carbon, would you not assume, in the absence of clear indications to the contrary, that such a lamp as that referred to in X question 105 was intended to operate upon the arc incandescent principle, and to feed the carbon forward as it wasted away?

A. I cannot say that I should, necessarily.

108 X Q. What is the effect of placing the arc incandescent construction in a chamber exhausted of air, or filled with a gas such as nitrogen?

A. I do not recall any such lamp, and cannot say what the result would be.

109 X Q. How are the arc incandescent lamps described as used?

A. In air, as far as I recollect.

110 X Q. What change in the phenomena would be produced by inclosing such a lamp in a chamber exhausted of air or filled with nitrogen?

A. I do not see that any material change would be produced. *In vacuo*, the phenomena might be complicated by such an effect as one gets in a Geissler tube. I do not know of any experiments relating to this matter, however.

111 X Q. The effect of producing a voltaic arc between carbon points *in vacuo* and in nitrogen has been investigated?

A. Yes.

112 X Q. Cannot you judge from the results of those investigations what would be the effect of placing an arc incandescent lamp in such atmospheres? 1896

A. Not with any certainty.

113 X Q. A wasting away of the carbon pencil at the joint is a feature of arc incandescent lamps, is it not?

A. It is.

114 X Q. Is not this feature characteristic of arc incandescent lamps, and not found in incandescent lamps?

A. I do not recall any incandescent lamp now in commercial use which possesses this peculiarity.

115 X Q. Would there be any such wasting away at the joint unless the particles of carbon were in less intimate contact at the joint than in other parts of the carbon?

A. I should think not, as far as I can call to mind the various actions which go on. Of course it would not at all follow from this that such a structure as you have described is an arc incandescent lamp.

116 X Q. Why would it not follow?

A. Because as I understand the hypothetical device under consideration, the current might be so strong as to render the pencil incandescent throughout its whole length, so that only a negligible amount of light in comparison with the whole would come from the joint. Especially might this be so if the pressure was such as to produce a very intimate contact between the two carbons. Still further, I think it probable that such an arrangement of parts could be made that there would be no incandescence at the joint although the pencil was made to incandesce.

117 X Q. Then the intimacy of contact between the carbon pencil and the carbon block would not determine the character of the lamp, in your opinion?

A. You are asking me to classify a hypothetical lamp which I have never seen, and the conditions of which are only indefinitely outlined; and your question, moreover, calls for an attempt to draw
a dividing line between lamps which might possess the char-
1897 acteristics of either, or both an arc incandescent and an in-
candescent lamp. This is difficult to do.

Adjourned till April 9th, at 11 a. m.

Resumed April 9, 11 a. m. (Witness continues his answer:)

The intimacy of contact would of course act to determine whether there was or was not a materially increased incandescence at the joint.

118 X Q. I call your attention to the lamps of Renier and Werdermann, illustrated and described on pages 56, 57, of Sawyer on Electric Lighting, put in evidence by the defendant; are these arc incandescent lamps?

A. I have always seen them described as such.

119 X Q. These lamps employ, do they not, a long carbon pencil pressed by a weight upon a block of carbon, a connection being made with the pencil near its point, so as to remove the resistance of the entire pencil from the circuit, and confine the electric current principally to the end of the pencil?

A. I understand from my previous knowledge of these lamps that they operate in that way. The description which accompanies the figures to which you have referred me is not at all clear, and does not give much of an explanation of the manner in which these lamps operate.

120 X Q. The figures show the pencils passing through clamps near their ends, with which one of the circuit connections is made, do they not?

A. The Werdermann lamp is clearly thus shown in the figure. I should judge the connections to be similar in the Renier. I imagine the figure of the Werdermann lamp is intended rather for a
diagram than for a picture of the lamp.

1898 121 X Q. The lamps of Starr, King, Konn, Bouliguine,
Fontaine and Farmer, described and illustrated in the same chapter of Sawyer's book, are incandescent lamps, as distinguished from arc incandescent, are they not?

A. I observe that Sawyer in his book referred to, does not seem to use the term arc incandescent or semi-incandescent lamp, or to use this classification. He simply speaks of "two types of incandescent lamps in use, those which burn in the air, and those in which the luminous conductor is inclosed in a globe exhausted of air, or containing an atmosphere of nitrogen or other gas for which carbon at high temperature has no chemical affinity." Sawyer's description of the lamps referred to in your question is in some cases very meagre, but they are all understood to be incandescent lamps.

122 X Q. Is the fact that the lamps of Renier and Werdermann burn in the air, an essential to their arc incandescent character, or would they still be arc incandescent lamps if inclosed in a receiver exhausted of air, or filled with nitrogen?

A. I don't know just how they might act *in vacuo.* I should suppose, however, that in this case, and undoubtedly with nitrogen, they might be operated as arc incandescent lamps.

123 X Q. Is the lamp illustrated in Fig. 10 of Shepard's English patent No. 13302, of 1850, and described in connection with that figure, an incandescent, or arc incandescent lamp?

A. I should understand it as being an arc incandescent lamp in fact, though the patentee does not distinctly describe it as thus operated. His statement is somewhat indefinite.

124 X Q. The statement of the patent that the light is produced by the incandescence of the charcoal cylinder E, does not lead you to classify it as an incandescent lamp?

1899 A. The statement itself would lead me to infer that the patentee meant to obtain light by incandescence from the carbon cylinder. It is not stated whether this incandescence was to be limited to the contact or otherwise. I do not think that the patentee had very definite ideas on the subject, and do not believe at all that he ever made and tried the lamp in question.

125 X Q. If enough current were passed through a lamp of this construction to make the carbon pencil E incandescent throughout its length how would you then classify the lamp?

A. If accuracy in classification were of any moment I should insist upon trying the experiment before making any such classification. If substantially all of the light came from the incandescent carbon, and the phenomena at the joint were comparatively insignificant, I should consider it an incandescent lamp.

126 X Q. Is it not the essential difference in construction between an incandescent lamp and an arc incandescent lamp that the former has a carbon pencil clamped firmly at each end, and the latter has the carbon clamped firmly only at one end and provided with means for feeding the pencil forward as it wastes away at the other end?

A. I have never seen this distinction made the basis of classification, and it would be a very unphilosophical one to make. I fail to see that such a difference of construction is essential. Our modern, commercial incandescent lamps are of course clamped firmly at each end, but this is not essential to an incandescent lamp.

127 X Q. How would you classify the lamp shown and described in the patent to Sawyer and Man, No. 205,144?

A. As an incandescent lamp.

Adjourned till 2.15.

Resumed at 2.15.

1900 128 X Q. In expressing the opinion of your last answer, did you take into consideration the fact that the current is principally confined to the point E^1 of the carbon pencil, that the carbon block D has a rounded top, and that the end of the carbon pencil resting on it is shown as slightly rounded, so as to bear on the carbon block for only a portion of the area of its end?

A. I did.

129 X Q. Did you also take into consideration the fact that the lamp is provided with a feeding device, namely, sliding weight F, for feeding the carbon forward as it wastes away at the end?

A. I took into consideration the presence of the rod F. The description of the operation of this rod, however, which I noticed in the patent, seems to me somewhat different from what one might infer from your question. The patent says: "The rod F exerts a pressure upon the carbon E, which continues the same without regard to the length of the carbon, and thus should fracture or a slight consumption of the carbon occur at the first lighting, or any subsequent lighting of the lamp, the necessity of taking down the same, renewing the carbon, and recharging the globe is obviated, inasmuch as the weight of the rod F gently forces the carbon through the clamp G, until a new contact between E and D is established." If by "feeding" you mean the operation thus described, I took it into consideration in my answer.

130 X Q. The weight F is described as gently forcing the carbon pencil through the clamp G:—would such a pressure of the pencil upon the carbon block, in view of the fact that the meeting faces of the block and pencil are rounded, and only a portion of the area of the end of the pencil is in contact with the block, produce a sufficiently good contact to prevent the arc incandescent action at the joint?

A. I cannot say without experiment whether such action would be entirely absent or not. I do not think, however, that it would play any material part in the phenomena accompanying the operation of the lamp.

1901 131 X Q. Why do you classify the Konn English patent of 1873 among the arc incandescent lamps in your answer to question 7?

A. I did not intend so to classify it, and it must have got into my list through some slip of the pen. In my 5th answer, I refer to it as an incandescent lamp, which it really is.

132 X Q. In classifying the English patent to Greener & Staite, No. 11076 of 1846, among the arc incandescent patents, did you intend to include all the forms of lamps described in that patent? I call your attention to the form described beginning at line 33, page

3, of the patent, in which a hollow cylinder of carbon is placed between two platinum cones connected with the circuit wires, the carbon cylinder being inserted, "so far into the cones at the two ends as to be in perfect contact therewith all around."

A. The patent in question describes a great variety of devices which I had assumed to be for arc incandescent lighting. I must have overlooked the particular device to which you refer, which I judge from the description is intended to operate by incandescence.

133 X Q. When was the arc lamp first introduced extensively for commercial use, if you know?

A. The arc lamp began to be employed for special purposes about 1845. After 1854, or thereabouts, it was used to an increasing extent, for light-house illumination. After 1873, or thereabouts, and to a certain extent before this, it was employed more or less in the illumination of dock-yards, buildings in process of construction, etc. Its use, however, was quite limited. About 1876 or 1877, it began to be used for street lighting, for which it has been extensively used from 1878 onwards. Since the latter date it has been very widely used.

134 X Q. Where were the early industrial uses of the arc light made?

A. It was used in some of the French light-houses, and also
1902 in some of the English light-houses as well. It was used, I
believe, in some of the French docks, and it was used for
lighting some of the streets of Paris.

135 X Q. Was it used industrially, so far as you know, say, prior to 1853, except its use for theatrical effects in Paris, as stated by Fontaine in his work on electric lighting?

(Objected to as immaterial.)

A. I do not recall any specific instances earlier than this. I think very likely it may have been used, but only to a trifling extent. I think it was sometimes used in illuminations, and for like purposes.

136 X Q. Where do you find the suggestion of Foucault to use gas-retort carbon for arc-light electrodes first recorded?

A. I have not looked up this matter, and therefore cannot state where it was first recorded. If it is a matter of any consequence I shall be glad to ascertain.

137 X Q. What is the foundation for your statement that Foucault made this suggestion about 1845?

A. That is my remembrance of the history of the art, I think there is no question about the fact, but in what place it was first published I do not recall.

138 X Q. Have you in mind any publication of the suggestion prior to, say, 1853?

A. I have none such in mind, and I never had occasion to hunt up the matter. It is a subject frequently referred to in books on electric lighting, and my remembrance has been that 1845 was about the time of the invention. I think I can very easily find a specific and authoritative statement if the matter is of sufficient importance to take the time for it.

139 X Q. What is the ordinary meaning of the English word charcoal?

(Objected to as immaterial.)

1903 A. The popular sense in which the word would now be understood by the public generally is the material commonly sold under that name.

130 X Q. What is the material?

A. A more or less impure form of carbon obtained by heating branches of wood in the absence of air.

141 X Q. Wood carbon or charcoal had been, prior to 1878, produced at various temperatures, both high and low and under quite perfect conditions as to the exclusion of air, had it not?

A. It had been.

142 X Q. And the electrical properties of such carbon had been, prior to that time, investigated, had they not?

A. They had to a certain extent.

143 X Q. And such wood carbon had been, prior to the date named, employed in exhibiting the heating effect of the electric current to the extent of producing light, both by means of the voltaic arc and by the incandescence of a slip or piece of wood carbon?

A. Such charcoal pencils were the first ones employed in the production of the voltaic arc. Sir Humphrey Davy observed in some of his experiments that charcoal became incandescent when a strong current was passed through it.

144 X Q. How widely known were the publications of the experiments of Davy and his contemporaries?

A. The experiments of Davy were, of course, widely known, as were also the experiments of many of his contemporaries.

145 X Q. Referring to the English patent of Konn, No. 3809 of 1872, what is the material intended to be used, in your opinion, for the incandescent material, as indicated by the word graphite?

A. I imagine that he means gas carbon; of course it might also be taken as meaning natural graphite.

146 X Q. Was the natural graphite or plumbago used in arc lighting, so far as you know, and is it suitable for such use?

1904 A. I do not recollect that it was so used. I do not think that it is well suited for this purpose.

147 X Q. Why do you think the word "graphite" in the Konn patent is intended to mean gas carbon?

A. The term "artificial graphite," often applied to gas carbon, had by the date of that patent frequently become changed in usage to "graphite" without any adjective. Hence, reading that patent, I should naturally infer that the artificial graphite was intended.

148 X Q. What did you mean in answer to question 7 by the statement in reference to the use of the word graphite in the Konn patent that "the effect of his patent necessarily would be to guide one reading it, and desiring to put into practice the invention

therein set forth, to the use of such graphite or gas carbon as was well known in the arts in connection with electric lighting"?

A. I meant that, in my opinion, a person reading the patent would select gas carbon or artificial graphite for use in the Konn lamp.

149 X Q. Why would he select it?

A. Because Konn states that his conductors are to be made "preferably of graphite."

150 X Q. Am I to understand that the fact that gas carbon was well known in the arts as suitable for the arc light has anything to do with your opinion in this matter?

A. You are. My feeling is, that if a term had a certain meaning in such electric lighting as was practised, and that same term were used without qualification in a publication relating to some new kind of electric lamp, the term would be understood in its usual acceptation.

151 X Q. That is to say, knowledge of the art of electric lighting generally would be applicable to the construction of such a patent?

A. So far as it related to similar matters, it would be. A man's knowledge of arc lighting would presumably be of use to him in considering other kinds of electric lighting.

1905 152 X Q. Referring now to the English patent of Roberts, No. 14198 of 1852, this patent describes, does it not, arc lamps as well as an incandescent lamp?

A. It does.

153 X Q. What kind of carbon do you find described as used for the arc-light electrodes?

A. The only kind particularly mentioned, as far as I observe, is graphite.

154 X Q. What do you understand that means in the patent of Roberts?

A. He seems here to use graphite as synonymous with carbon, although his expressions are somewhat obscure. If the patent were a more recent one I should naturally assume graphite to mean gas carbon. At the early date of the Roberts patent I do not feel certain whether it means natural graphite or artificial graphite, the latter would undoubtedly be better suited to his purpose.

155 X Q. Why does the early date of the patent make you doubtful as to the meaning of the word graphite?

A. Merely because of my impression that the term graphite as applied to the gas carbon was not of immediate introduction. At the same time I have not considered this matter with special care, and may not be correct in my inference.

156 X Q. Do you find the word "charcoal" used anywhere in that patent in connection with the arc-lamp electrodes or pencils?

A. I do not. They are spoken of as either of graphite or carbon.

157 X Q. Is there any indication that this patent was translated from the French or other foreign language?

A. I know of none.

158 X Q. Is there any indication in the patent that the descrip-

tive words are used in any other than their ordinary English meaning?

A. I suppose that they are intended to be used in such a
1906 sense as to be understood by those skilled in the art at the
date of the patent.

159 X Q. Question repeated.

(Objected to as indefinite and ambiguous, also for immateriality.)

A. As I have already said, the patent is somewhat obscure in places. For example, it speaks of using "graphite or carbon." Now, if this means, as I have suggested in my answer to cross-question 154, that the two terms are synonymous, one of them is certainly not used in its ordinary English sense. On the other hand, if the expression means either graphite or carbon, the term carbon is not used in its ordinary English sense, since graphite is excluded from its meaning. Perhaps, again, it may mean either natural graphite or artificial graphite, that is, gas carbon. Again, if by "ordinary English sense," you mean the popular every-day sense of words, then the word graphite throughout the whole patent is not used in its ordinary sense, unless we assume the word to mean plumbago or natural graphite. Again, the reference to coke in connection with the incandescent lamp referred to in the patent does not seem to be in the ordinary English sense of that term.

160 X Q. Aside from what may be the indefiniteness or ambiguity of the patent, in your opinion, is there any indication in the patent itself that the words are used in any other than their ordinary English sense?

A. I do not know that I fully understand the question. As I understand it, however, you ask me whether aside from the known state of the art at the date of the patent, and without taking into account in any way what materials were or were not habitually used at that time, and assuming the document to be read and construed simply as a piece of English prose, appealing alike to any one understanding the language, whether otherwise informed or not, and not written with any reference to its meaning to those
skilled in the art of the time; whether, making these
1907 assumptions, I observe anything in the patent to show that
the words have any sense which they would not naturally
suggest to such a person. I do not observe that there is anything, unless it be the expression "graphite or carbon," which would show to any one, knowing what these substances were, that they were not used in their ordinary popular signification.

161 X Q. Referring now to the English patent of Binks, No. 119 of 1853, is there any indication that this was translated from the French or other foreign language?

A. Not so far as I am aware.

162 X Q. Omitting to consider the use of the word charcoal in connection with carbonized lignite, do you find anything in this patent of Binks to indicate that the expression "charcoal" is intended to have other than its ordinary English meaning?

A. I do not observe anything in the mere language of the patent itself, beyond the reference to carbonized lignite.

163 X Q. Do you disagree with the statement made by defendant's expert, Prof. Brackett (with reference to this Binks patent), that "lignite is partially-reduced wood, or other vegetable matter, in its progress from its condition in the organic state toward coal"?

A. I suppose that the statement is literally correct, though to me it seems somewhat misleading. I am not a mineralogist, but I think I am right in my understanding that lignite is classified as a mineral. I should think it was rather a kind of coal than a kind of wood. I have limited my consideration to the sentence quoted from Prof. Brackett's deposition, and have not considered the remainder of the answer in which this quotation occurs.

164 X Q. Lignite retains, does it not, to a very large degree, the grain and fibre of the wood from which it is partially reduced?

A. I cannot say to what extent it does this. As I have
1908 already said, I am not an expert in mineralogy, but the fact
that this substance is classed with minerals would lead me to
suppose that great changes had taken place in its structure.

165 X Q. Is not a carbon made by carbonizing lignite a carbon made from a fibrous material?

A. I suppose that would depend upon the sense in which the term fibrous material was used. If one were directed to make use of a carbon derived from fibrous material, I am confident that he would never think of using lignite. There is a certain sense, in which, I suppose, carbon made from lignite might be said to be carbon made from a fibrous material, just as there is a sense in which bituminous or even anthracite coal might be spoken of as a carbon made from fibrous material, since they all originated in woody tissue. But in all three cases it seems to me that the term "carbon made from fibrous material" can only be applied by a violent stretch of language.

166 X Q. Do you mean by your reference (in answer to question 5), to the English translation of the Gaudoin patent, that anybody skilled in the art at the present time would confuse the expressions "charcoal" and "retort carbon"?

A. I simply mean to make a statement of fact with regard to the apparent explanation which the translator of that article gave of the French term thus rendered. It seemed to me to bear on the frequent translation of the French word "charbon" by the English word "charcoal."

Adjourned till 7.30 p. m.

Examination resumed at 7.30 p. m.

167 X Q. The suggestion on the margin of the translation rather shows, does it not, that the translator was ignorant of the true translation of the French expression?

A. He does not seem to have understood the technical terms involved.

168 X Q. I show you a certified copy of French patent No.

1909–1919 97583, dated 18th December, 1872, and granted to Lodyguine & Co. Does this patent describe an incandescent lamp?

A. It does.

169 X Q. Is not the following description of the incandescing conductors found in that patent: "Les conducteurs m, m', m'' doivênt etre en coke, en graphite ou toute autre substance qui pourrait servir au memê, but et qui remplirait les mêmes conditions"? Will you also kindly translate the matter into English?

A. It is. The paragraph reads as follows: "The conductors m, m', m'' may be of coke, graphite or any other substance which would serve for the same end and which would fill the same conditions."

The patent referred to is offered in evidence by defendant's counsel, and the same is marked "Defendant's Exhibit Lodyguine French Patent," H. C. M., spe. ex.

Complainant's counsel objects to the foregoing exhibit for the reason that defendant's time for taking proof has expired.

At request of defendant's counsel complainants admit that the said exhibit is a correct copy of a French patent granted as set forth in X Q. 168.

170 X Q. Would you include this patent among the published descriptions of Lodyguine lamps which you have grouped together in answer to Q. 7?

A. I have not seen the patent until this moment. I see no reason for not including it among such descriptions.

171 X Q. In ascertaining what substances would be included by the expressions used in the paragraph quoted in X Q. 169, would you apply the same course of reason which you have applied to the Konn and Koslorff patents in answer to X Q. 7?

A. I should, if I understand the question correctly.

1920 172 X Q. What substances would be so included, in your opinion, by the paragraph quoted from the patent in X Q. 168?

A. I am sure I do not know. The statement in the patent is one of those indefinite expressions which seem to indicate merely that the patentees reserve the right to use any equivalents for the substances specifically mentioned. It is as if they said, "You may use coke, graphite or anything else which will prove operative."

173 X Q. Does not this paragraph throw some light upon the expression, "preferably graphite," employed in the English patent of Konn, No. 3809, of 1872?

A. I do not see that it does. I have not noticed, as far as I remember, any particular obscurity in that patent which seemed to render its meaning doubtful.

174 X Q. Does not the language of the French Lodyguine patent indicate that, besides coke and graphite, such other substances could be used as were known in connection with electric lighting?

A. The language indicates that one may use any substance which fulfills the requisites of such a lamp.

175 X Q. Would not the knowledge with regard to materials used in arc lighting be applicable in construing the language, the same as you found such knowledge applicable in construing the Konn and Koslorff English patents?

A. We should, of course, apply our knowledge of arc lighting operations to the method in question. If we use our judgment in applying it, it will doubtless be of value.

176 X Q. You have referred several times to the book entitled "Electric Lighting," by H. Fontaine, translated by Paget Higgs, published in London, 1878; is this a copy of the book you referred to? (Book handed to witness.)

A. Yes.

177 X Q. What is it a translation of?

A. I understand it to be a translation of a work entitled "Eclairage á L'Électricité," par H. Fontaine, published in 1877.

1921 178 X Q. Is the French publication the book I now hand you? (Book handed witness.)

A. Yes.

Adjourned to 10 a. m., 10th April.

April 10—10 a. m.

179 X Q. Referring to cross-question 133, I desire to call your attention to the statement made at page 126 in Higgs' translation of Fontaine to which you have referred. Is Fontaine's statement that the electric light was first applied to light-houses in 1863 probably correct?

A. I had the impression that experiments of this kind had been carried on at an earlier date than this, but my impression may be incorrect. As far as I know, the electric light was first regularly used for that purpose at or about that time.

180 X Q. Is the statement contained at page 105 of Higgs' translation that "the first permanent introduction of the electric light was realized in 1873, at Paris, in the workshop of the Gramme Company," the basis of your statement in answer to cross-question 133 as to the use of arc lights after 1873 or thereabouts?

A. The dates mentioned in my answer were simply intended to indicate my impression as to the matter inquired of, as I did not suppose the question demanded rigid accuracy. I think it probable that my impression was in part at least derived from Higgs or from the original French of Fontaine, as I had read both of these books.

181 X Q. You have stated, in answer 7, in connection with the Konn English patent, No. 3809, of 1872, that "there is not in the patent the remotest intimation that anything but disadvantage could result from using carbon other than graphitic carbon."

1922 Do you mean by this that there is anything in the patent showing that disadvantage would result from the use of other than graphitic carbon?

A. The inventor says that the conductors "are preferably graphite." I should infer from this that there would undoubtedly be certain disadvantages in the use of other forms of carbon. Otherwise I do not see why graphite should be preferable. And from the fact that this inventor thinks it worth his while to especially instruct one wishing to employ his invention, that by using graphite he will best secure the advantages of that invention, I should naturally infer that certain disadvantages would result from the use of other forms of carbon; that the patentee realized this and that he desired so to instruct the public.

182 X Q. Then the basis for your statement which is quoted in my question 181 is the expression in the patent "preferably graphite"?

A. Certainly.

183 X Q. In the English patent to Burleigh and Danchell, No. 3164 of 1857, charcoal and gas carbon are stated as different substances, are they not?

A. In his numeration of the substances which he proposes to use, the patentee separately mentions, among other things, "animal or vegetable charcoal" and "gas carbon."

184 X Q. In the original application for the patent in suit, charcoal and gas carbon are stated as different substances, are they not?

A. They are.

185 X Q. Is there anything in the language itself which you have quoted from Ure's Dictionary of Arts, Manufactures, and Mines, to show that the expression "charcoal" is used in other than its ordinary sense?

A. Dr. Ure says that "in nearly all the arrangements the beautiful arc of light produced between the poles, from the points of the hardest charcoal, has been the illuminating source." Now, for twenty years prior to the date of this publication, gas carbon had been used for that purpose, and the term "charcoal" had
1923 been used in England to designate this gas carbon. Dr. Ure
wrote originally in England as an authority on these matters, and his statement would be grossly untrue if by "charcoal" he meant the article popularly designated thus. For these reasons it seems to me unquestionable that his language is to be understood and would be understood by one skilled in the art as I have interpreted it.

186 X Q. You have misunderstood my question. I do not want to know how you would modify the ordinary meaning of the words by reference to what you consider was the practice of the art at the date of the publication. What I want to know is, whether there is anything in the language itself which excludes the idea that the ordinary meaning is to be given to the words employed.

A. I do not think that I get at the full sense of the question. It is not quite clear to me what I am to understand by "the ordinary meaning" of the terms. I suppose that the ordinary meaning of the terms employed in a scientific work is the meaning which they have in the art to which that work relates; and certainly I did not propose to in any way modify that ordinary meaning, which one skilled in the art would attach to these words. To one absolutely ignorant of the art, the paragraph quoted from Ure's dictionary would be entirely unintelligible. He would not know what was meant by a battery or by the arc, or by the poles; and if he attached to these words only their common, popular meaning, he would, to say the least, find the statements exceedingly confusing. On the other hand, if he attached to the various terms employed their usual signification in the art, he would understand all of them in their true and proper sense.

187 X Q. Your position, then, is that at the date of Ure's publication, by the ordinary meaning of the word "charcoal" in the art of electric lighting, the substance which is known as gas carbon was intended?

A. That was an ordinary meaning of the term in the art.

1924 188 X Q. Do you think that at that time, or at any other time, in the art of electric lighting, the use of the word charcoal would exclude the idea of wood carbon?

A. Not necessarily. I assume from the general tenor of the preceding questions that by "wood carbon" you mean what is popularly know- as "charcoal."

189 X Q. I mean to include charcoals produced at the best temperatures and under the best conditions for producing perfect carbonization, such as were known to and employed by Davy and others of his date, such as are described by Violette, by Watts' Dictionary of Chemistry, and by various English patents, including that of Harrison, No. 588, of 1857, and that of Slater and Watson, No. 212 of 1852, and by other publications; and I repeat the last question with this understanding.

A. Not necessarily. Of course what it did or did not exclude in any given case would depend largely on the context.

Adjourned till 3.20.

Resumed at 3.20.

190 X Q. Are you aware of the fact that the term "charcoal" is defined in Ure's dictionary as "the fixed residuum of vegetables exposed to ignition out of contact of air"?

A. I do not, of course, recollect the particular wording to which you refer. I should expect to find in it some difinition of this kind.

191 X Q. Are you also aware that Webster defines charcoal as "coal made by charring wood under turf, or in other circumstances to exclude air; wood coal," and also that Worcester defines 1925 charcoal as "coal made by charring or burning wood under turf, or with little access of air; coal from wood"?

A. I never had occasion to look up the word either in Webster or in Worcester; but the definitions which you have cited are what I should expect to find there.

192 X Q. Is there anything in the language used in the Way English patent to indicate that charcoal is used in other than its ordinary sense? I call your attention to English patent No. 2841 of 1857.

A. The only patent of Way which I have before me is 2841 of 1857. There is nothing in the mere language of this patent itself to indicate the sense in which charcoal is used.

193 X Q. Why, then, do you hold the opinion that it means gas carbon?

A. Because gas carbon was the substance universally in use at the date of the patent, for arc lighting; and in a patent issued the year before to the same Way, No. 2547 of 1856, the patentee makes a statement which can only be reconciled with universally known facts by assuming that he uses the term charcoal to indicate gas carbon. The matter which I refer to is quoted in my answer to interrogation 5.

194 X Q. How do you know that gas carbon was universally used for arc lighting in 1857?

A. From the statements which I have seen with regard to the introduction of that material by Foucault and its subsequent use. I do not think there is any question as to the facts.

195–'6 X Q. Can you refer me to the publications where these statements can be found?

A. I haven't any particular publication in mind since this is a matter which I had supposed unquestioned, and which I had accepted as true for years. I suppose that I originally learned it when I first studied physics. I do not doubt, however, that proper search would abundantly substantiate my belief.

1926 197 X Q. Was not arc lighting in its experimental stages in 1857?

A. No; not for the purposes for which it was employed. Of course, in relation to our commercial use of arc lighting, what was done then would be considered experimental.

198 X Q. How large was the experimental use of arc lighting in England in 1857?

A. What I had in mind was the use of the arc light in the theatre, and for illuminations; also its use as a brilliant source of light for optical purposes. It does not seem to me that these uses are properly called experimental, though of course its use at that early date was very limited. If one might judge by the number of patents prior to 1857 which I find put in evidence by defendants in this case, the matter of arc lighting might be supposed to have passed beyond a purely experimental stage.

199 X Q. Do you consider that the terminology of the art was such in 1856 and 1857 that the word charcoal as used in the two patents of Way excludes the idea of wood carbon?

A. I was led to conclude that Way used "charcoal" in the sense of "hard carbon" from his statement that "electrodes of charcoal had usually been employed" for the arc light. Since the electrodes which had usually been employed were of hard carbon, and since the word "charcoal" had been used to designate such hard carbon in electric lighting, I inferred that this was what was meant by Way; otherwise the statement made by Way would be incorrect in a matter regarding which he was presumably well informed; and, since the term is apparently used in this sence in the Way patent of 1856, I inferred that Way used it in the same sense in his patent of the next year.

200 X Q. Was the terminology of the art such in 1856 and 1857, that the word "charcoal" excluded wood carbon?

1927 A. I understand now that you have dropped the Way patents out of consideration in the question, and ask me whether in the art of electric lighting the word "charcoal" was never so used as to include wood carbon. My answer is that the word "charcoal" was frequently so used as to include wood carbon.

201 X Q. In arriving at the conclusion that the Way patents mean "gas carbon" when they say "charcoal," you are obliged, are you not, to discard from the knowledge of the art the use by Davy and his contemporaries of wood carbon for arc lights, and also to discard from the state of the art the knowledge furnished the art (at a later date than the date you have fixed for the contribution of gas carbon by Foacault) by the paper of Violette, and by the English patents of Harrison and Slater and Watson, referred to in cross-question 189.

A. By no means. The substances used by Davy were superseded by the gas carbon of Foucault. As to Violette, I never heard of his carbons being in use for electric arc lighting; and while I cannot of course say that they had never been tried by any one except himself, yet I am very confident that no such use had been made of them as would in any way influence the terminology of the art.

The same remark applies to the process described by Slater & Watson. It was certainly never used to any extent, if at all.

With regard to the invention of Harrison, this could not, of course, have influenced the terminology of the art at the date of Way's patent of 1856, because it was not issued until 1857. With regard to the relation between Harrison's patent No. 588, of 1857, and Way's patent, 2841, of 1857, it is clear that, since Harrison's patent was not issued until August, 1857, while Way's was issued in March, 1858, no change could have been effected in the terminology of the art by Harrison's patent in that brief time, even if that had been a document of recognized importance. Still more is this
the case when the carbonizing process, because of which I
1928 suppose you refer to the patent, is described in only three or
four lines, and is one which has never come into use in the making of arc-light carbons. But it should also be noticed, as bearing on the possibility of the patent to Harrison effecting a change in the terminology of another patent issued in the same year, that the Harrison patent is sealed the 28th of August, 1857, which is the earliest date at which it could have become known to the world, and so begun to affect the terminology of the art, while the patent to Way under consideration is dated Nov. 10, 1857, less than three months after the issuing of the patent to Harrison. It certainly is not probable that Way read the Harrison patent on the day of its sealing, and failed to put his own provisional specification in shape until the day at which it was received at the British patent office, so that there was only about two months at the outside for the Harrison patent to work a change in the terminology of the art. And inasmuch as there is absolutely nothing in the Harrison patent to make any such change, I see no reason

to suppose that Way was influenced in his use of words by the patent of Harrison.

The use of gas carbon by Foucault really marked an epoch in electric lighting, but none of the later devices which you have mentioned were of marked importance.

202 X Q. In considering what is meant by the expression "sticks of carbon," occurring in the English patent of Koslorff, No. 441, of 1875, as descriptive of the incandescent conductors used in his lamp, you arrived at the conclusion, as I understand you, that gas carbon was necessarily intended, because you thought that there could be no question that the patentee referred to such carbons as are used in electric arc lighting; do you mean to take the position that in making the Koslorff lamp under his patent one would not be entitled to take advantage of the various kinds of carbon that had been used in arc lighting, including pulverized and moulded mixtures of various kinds, as well as the wood carbon of Violette, of Sidot, Watt's Dictionary, Harrison, Slater & Watson.

1929 A. I suppose that one wishing to construct such a lamp would be at perfect liberty to use whatever he pleased, but there is nothing whatever in the patent to lead him to make use of the various substances mentioned in your question. If we consider the lamp described in British patent, 441, of 1875, in connection with the earlier lamps originating with the same firm, I think that one would be led to use graphite and graphite only. Furthermore, considering patent 441 of 1875, by itself, it seems to me that in view of the universal use of graphite as the form of carbon employed in electric arc lighting, and of the fact that these hard-carbon electrodes were commonly spoken of as "the carbons," it would be almost certain that one purposing to construct the lamp of Koslorff's 1875 patent, would select graphite.

203 X Q. Is there anything in the patent to exclude the idea that the patentee intended to take advantage of all forms of carbon known in the art of electric lighting?

Ans. I think it very likely that the patentee so drew his patent that it might be held to cover any form of carbon, but there is nothing in it to indicate that other forms of carbon could under any circumstances be preferable to hard carbon. I feel certain that if the patentee had intended to indicate that some other substance than hard carbon was preferable, he would have mentioned it. And still more, considering his use of hard carbon in his earlier and analogous lamps, it appears to me that if he had not intended that this lamp should be made of hard carbon, he would at least have mentioned some other form.

204 X Q. The fact is, however, that he mentions carbon generally, and not any particular form of carbon specifically?

A. He says "carbon" only.

Adjourned till 7.30.

1930 Continuation of Prof. CROSS.
Resumed at 7.45 p. m.

205 X Q. You have stated, in answer to question 79, and with reference to the Gaudoin carbon pencils of the smallest sizes, that they were "adapted to be used, and in fact were used with arc incandescent lamps;" do you mean that they were not used in incandescent lamps?

A. I cannot say as a matter of fact that they were not used at all in incandescent lamps; they may have been so used; but there is no evidence so far as I know that such was the fact. What I particularly wished to indicate by my reference to their use in arc incandescent lamps was the fallacy of the assumption made by Prof. Barker that "some of them being not over a millimeter or two in diameter, were, therefore adapted only to the production of light by incandescence." That is, Gaudoin describes specifically a process intended for the production of hard-carbon pencils for use in arc lighting. Some of these pencils were made small in diameter. Prof. Barker concludes from this, and from this only, that these could have been used only for incandescent lighting. As a matter of fact, they were better adapted for arc incandescent lighting, and moreover they were actually used for that purpose. I only wanted to point out that Prof. Barker's conclusion in this matter was not justified by his premise.

206 X Q. You did not intend, then, by your answer to question 79 to exclude the idea that such carbons were in fact used in incandescent lamps?

A. I did not. I cannot say but that they may have been used, but do not recall any evidence that such is the case.

207 X Q. You feel quite certain, however, that they were used in arc incandescent lamps?

A. That is my understanding.

208 X Q. What evidence of that fact did you have in mind at the time of making your answer to question 79?

1931 A. I recall having seen a statement in some book on electric lighting to that effect. My impression is that there is a reference to it somewhere in Higgs' book.

209 X Q. If it should appear as a matter of fact, that these small Gaudoin pencils were used in incandescent lamps, would you change your views as to the intention of Gaudoin in making them?

A. If they were merely used experimentally or occasionally for that purpose, this would not modify my opinion in that regard. If they were used habitually and in large quantities, I think it would be fair to conclude that they were made at least in part for that purpose.

210 X Q. Do you think they were used more than experimentally or occasionally for arc incandescent lamps?

A. I cannot say. Of course, in a sense the arc incandescent lamps themselves were experimental, so that the same would be true with regard to any special size of carbons made for them.

211 X Q. Do you not think that the fact as to the use of these carbons is the best test of the purpose for which they were intended?

A. Yes, that seems to me to be a fair conclusion, assuming, of course, that the use was sufficiently extensive to demand the construction of such material.

212 X Q. You state in answer to cross-question 205, that "as a matter of fact, they were better adapted for arc incandescent lighting;"—do you mean by this that in 1877, when these Gaudoin pencils were made, the character of carbon best adapted for incandescent lighting was understood?

A. I did not intend to be understood as saying this.

213 X Q. That statement was made, then, I take it, from your present information as to the desirable characteristics of such a carbon?

A. That is true to a certain extent. My statement, however, was
made with reference not so much to the material of which
1932 these small carbons were made as to their dimensions. I was
doubtless guided by my present knowledge in making that
answer. As a matter of fact, however, although we are discussing these Gaudoin pencils as though they were regular and well-known articles of commerce, the only definite statement with regard to them which I find anywhere in this case is the statement of Prof. Barker, in his answer to the 50th question, that he knows, apparently from having seen them, that these pencils were made of various sizes, some large and some small, even not over a millimeter or two in diameter. There is nothing in this to show that these small pencils were other than samples shown at some exhibition, merely as illustrative of the process. Still further, Prof. Barker does not say that the pencils which he saw were intended for the production of any kind of a light by electricity; and so far as I can see, these particular pencils may have been intended not for electric lighting, but for some of the other purposes for which, as stated by him in his patent, Gaudoin made pencils of carbon.

(The entire answer after the second sentence objected to as irresponsive and volunteered.)

214 X Q. What is there in the dimensions of these small carbons that would make them ill-suited for use in incandescent electric lighting?

A. I don't think that I have made the statement that they were ill-suited for incandescent electric lighting, but that they were better suited for arc incandescent lighting. These pencils, especially if they have the diameter of two millimeters, are large for incandescent lighting, unless their length is very short; and if the length used is to be very short, I should hardly think they would be made in long pencils, or in rods of sufficient length to have the name "pencil" applied to them.

215 X Q. Should you think that a diameter of 1.6 millime-
1933 ter and a length of from 15 to 18 millimeters would be large
for use in incandescent lamps of the character known in
1877?

A. I think there is no doubt that some of the incandescent lamps then devised were intended to employ a carbon rod as large as this, though I am not positive, in the absence of direct measurements.

216 X Q. Would a round pencil having a diameter of 1.6 millimeters, and a length of 15 millimeters, be radically different in size from the carbon for incandescent lamps, the proportions of which are given for a small form of lamp on page 99 of Sawyer's book on Electric Lighting?

A. It would not.

217 X Q. Would such a carbon pencil be radically different in size from the size of the carbon shown in figure 3 of the patent in suit?

A. I should say not.

218 X Q. I understand that your opinion, that the small Gaudoin pencils were used in arc incandescent lamps, is based, at least in part, on some statement in Higgs' translation of Fontaine's book, which has been several times referred to in the course of your examination. Please refer me to the statement.

A. It is based on a statement which I have read, and *and* which I think is somewhere in Higgs' books. I do not recollect where, however, but should be glad to try and find it. My own copy of Higgs is at present in New York, so that I have no access to any mark which might indicate its presence.

219 X Q. It is a fact, is it not, that the methods of making the Gaudoin carbon pencils, as well as carbon pencils of some other makers, and also various tests of the carbon pencils are described in chap. 3 of Higgs' translation, and in chap. 3 of the original book of Fontaine's, both of which I now hand you?

A. That is the case.

Adjourned till April 11, 1889, at 11 a. m.

1934 Resumed April 11th, 11 a. m.

220 X Q. It is also true, is it not, that in chap. 11 of each of the books referred to in cross-question 219 the use of Gaudoin pencils of small diameter in incandescent electric lamps of the Konn construction is described?

(Objected to unless the term "Gaudoin pencils" be made more definite; the necessary for this, in order to relieve the question from ambiguity, appearing from the fact, as shown by chap. 3 of Higgs' book, that Gaudoin seems to have had various modes of making carbon pencils.)

(Def't's counsel states that it sufficiently appears by the deposition as already taken, that the witness is amply able to give the testimony in the case, and that testimony by counsel is evidently improper.)

A. Reference is made to some laboratory experiments with Konn lamps using "in Gaudoin artificial carbon," 0.0016 meter in diameter, and 0.018 meter long in their incandescent part. In the French Fontaine the carbons in question are referred to as "Charbons artificiels Gaudoin."

221 X Q. Would your answers to cross-questions 216 and 217 have been different if the proportions of the carbon pencil referred to in those questions had been 1.6 millimeters in diameter and 18 millimeters in length, as stated in your last answer, instead of the different length stated in question 216?

A. They would not.

222 X Q. It is a fact, is it not, that, in the experiments with the Gaudoin carbons in the Konn lamps referred to by Fontaine, the incandescence of the carbon was carried to a much higher degree than is usually practised in modern incandescent lamps?

Objection continued.

1935 A. That is my understanding.

223 X Q. Would such a higher degree of incandescence have any effect upon the length of life of the carbon?

A. I should expect that it would tend to shorten the "life" of the carbon.

224 X Q. You have stated in answer to question 79, that the term "electric lighting" was used at the date of the original Gaudoin patent "only as referring to arc lighting;" did you intend to make any distinction between the use of that expression on July 12, 1876, the date of the original Gaudoin patent and April 7th 1877, the date of the first certificate of addition to the Gaudoin patent?

A. I did not have any such distinction in mind in answering that question. What I meant by my statement regarding electric lighting was that the term "electric lighting" was understood to mean arc lighting, and that such was the sense in which that expression would be taken. I did not intend to state that no other kind of electric lighting had been suggested at that time, but that, if lighting by incandescence was meant, it would be distinctly stated. Still further, the expression "pencils for use in electric lighting" would certainly have been understood as referring to arc lighting.

225 X Q. In view of the use of the small-sized Gaudoin pencils in incandescent lamps as stated by Fontaine, and in view of your own recollection of having seen a statement that such pencils were used in arc incandescent or semi-incandescent lamps, do you wish to make any modification of your answer to question 7, with respect to the classification of the Gaudoin patent and certificates of addition as being one of the exhibits which relate "only to arc lighting and to the preparation of carbons for this purpose"?

A. I do not.

1936 (Def't's counsel offers in evidence the title page and chapters 3 and 11 of the book entitled "Electric Lighting, by Hippolyte Fontaine, translated by Paget Higgs," and also the title page and chapters 3 and 11 of the book entitled, "Éclairage á L'Électricité, par Hippolyte Fontaine," which have been referred to by the witness, and the same are marked respectively, "Def't's Exhibit Higgs' Translation of Fontaine's Book," and "Def't's Exhibit Fontaine's Book," H. C. M , Spe. Ex.)

(The foregoing exhibits are objected to by compl't's counsel as incompetent, and immaterial, and particularly because def't's time for taking proofs and offering evidence has expired. In view of the course of the cross-examination, compl't's counsel believes that the only object of defendant in offering these exhibits is to get before the court matters contained in the chapters specially named and not referred to in the examination of the witness.

(Adjourned till 2.15 p. m.)

(Resumed 2.30 p. m.)

226 X Q. Is it not a peculiarity of arc-light points, or electrodes, made of charcoal, that they are rapidly consumed?

A. By "charcoal" I will assume you to mean the ordinary charcoal of commerce, or such charcoal as was used by Davy. It is true that this charcoal gave trouble from its too rapid consumption, among other causes.

227 X Q. Will you consult Ure's Dictionary and see if I have given in cross-question 190 the correct definition of "charcoal" as given by Ure?

A. That is the definition given in the supplement to Ure's Dictionary, published in New York, in 1866.

1937 228 X Q. Is this definition found in the same volume from which you quoted in answer to question 5?

A. It is.

229 X Q. Do not the carbons of Davy, Violette, Sidot, and Gaudoin come within the terms of Dr. Ure's definition of charcoal?

A. The carbons used by Davy unquestionably do. Violette's process produces charcoal by the action of superheated steam upon woody matters. I have never heard the term "ignition" applied to the application of steam to a substance. I see nothing in Violette's paper to indicate that the woody matters used by him were kept out of contact with air, that is, that the steam employed is kept perfectly free from air. In strictness, therefore, it seems to me that the carbon of Violette does not conform to the definition cited. In Sidot's process, the carbon is produced by placing wood in a porcelain tube through which the vapor of bisulphide of carbon is passed, and the tube is then carried to a red heat. If we understand this simple, intense heating to be "ignition," in the sense of the definition, then there is a sense in which carbon obtained by Sidot's process may be included within the definition. If by ignition is meant ordinary combustion by oxidation of the contained hydrogen and hydrocarbons, the process is not included. Ure's definition further says that the ignition is to be performed "out of contact with air." Now, if by "out of contact with air" he means that it may be in contact with any other substance whatever, provided air is excluded, the wood in Sidot's process might be spoken of as carbonized "out of contact with air," since it is surrounded by an atmosphere of the vapor of carbon bisulphide. I do not think, however, that this is the sense in which the definition was intended to be taken, because, "the fixed residuum of vegetables exposed to ignition out of contact with air," but in contact with certain other substances, for example with oxygen, would not be charcoal. In the case suggested, it would be wood ashes. Whether or not 1938 my reasoning is correct, this thing is certain; in his paper, Sidot does not once speak of this substance as charcoal, but always speaks of it as carbon—a "new carbon" he calls it. In another place he speaks of it in the original as "*charbon de bois transformé en coke*;" which I understand to mean wood carbon transformed into coke.

I assume that the Gaudoin carbons to which you refer are those described in the first certificate of addition taken out April 7, 1877. These carbons are formed from wood which is impregnated with various substances, either animal, mineral or vegetable (which substances contain carbon). They may also be subjected to the action of various chemicals. In a sense, I suppose, these might be included within the definition of charcoal cited, but it does not seem to me that the definition properly applies to them. It seems to me that what the definition is really intended to imply is, that charcoal is a substance which is nothing other than "the fixed residuum of vegetables exposed to ignition out of contact with air," and that a material which, beside receiving this treatment, has also undergone special chemical treatment, and an integral portion of which might be the residuum of mineral or perhaps of animal matter rather than of vegetable matter—still less than of vegetables—would not fairly be included within the definition cited.

Gaudoin in the document under consideration does not once speak of his carbon even as "a charcoal," still less as "charcoal."

It does not seem to me that the carbons of Violette, Sidot and Gaudoin properly come within the terms of the definition cited.

230 X Q. At a temperature of 1500° Centigrade do you not think that wood would be charred so as to reduce it to charcoal, even if surrounded by an atmosphere of steam raised to this high degree of heat?

A. I do not doubt that wood does become charred under the circumstances mentioned as Violette states. If you apply the 1939 term "charcoal" to any wood which is charred or carbonized, then it is true that this wood would be reduced to charcoal under such circumstances.

231 X Q. Would wood subjected to the high temperature evidently used by Sidot be charred so as to produce the fixed carbon residuum, even if surrounded by an atmosphere of carbon bisulphide?

A. It would, according to Sidot's statements, the correctness of which I do not doubt.

232 X Q. Have you any doubt, considering the results obtained by Violette and Sidot, as to the fact that the carbonization in each instance was carried on by charring the wood, while air was excluded?

A. There appears to be no question as to the process of Sidot. I do not feel positive in regard to the process of Violette.

233 X Q. Where in the patent in suit do you find any description of the particular form meant by the expression "arch-shaped"?

A. There are pictures of the arch-shaped form in the drawings, and the specification says, "the accompanying drawings show all our improvements embodied in an apparatus or lamp * * * being the form in which we have practically used it," and a specific reference follows. The patentees also say in the specification, "We have also used conductors of varying contours, that is, with rectangular bends instead of curvilinear ones, but we prefer the arch shape." Also in claim 1, the conductor is referred to as having "an arch or horseshoe shape," and in claim 4 it is spoken of as "having the form of an arch or loop."

234 X Q. Then aside from the illustration by the drawings, there is no description of what is meant by "arch shape"?

A. I think there is; the arch-shaped conductor is described by implication in the specification as a conductor with curvilinear bends. It is also described in claim 1 as having a "horseshoe shape." It is also described in claim 4 as having the form of a "loop."

1940 235 X Q. Where in the patent is there any description or illustration of the horseshoe shape and the loop shape?

A. I do not find any specific description or illustration of the horseshoe or loop as distinct from arch-shaped carbons in general. Nor do I see that the meaning of these terms would be made any plainer by further description or illustration.

236 X Q. Are you aware of the fact that arches are common with angular instead of curvilinear bends, and that one form of arch is similar to an inverted V?

A. I do not understand what is meant by an angular bend, and have not in mind the kind of arch meant by this expression. The inverted-V construction referred to, is not what is ordinarily understood by the term "arch-shaped," though I think that I remember having seen pictures of such a structure in architectural books, as one which was used considerably before the Norman conquest in England, and I believe that it was spoken of as a V-shaped arch, or something of that kind. Certainly the term "arch" is applied to such a construction by an extension of its original meaning.

237 X Q. Would the ordinary Gothic arch be within what is ordinarily understood by the term "arch-shaped"?

A. This construction is undoubtedly arch-shaped. It is a pointed arch.

238 X Q. Have you ever heard that a helix, or coil, is known as an arch?

A. It is not customary to designate it thus, and it is not a term which one would naturally apply to it, since the curve makes a complete turn of at least 360 degrees, instead of being limited to a less number of degrees. But we call the roof of a long tunnel "arch-shaped," and we call the tunnel itself "arch-shaped," even though its section extends over 180 degrees, and as is often the case, has the shape of a horseshoe. Or, looking at the matter from a geometrical point of view, if we have an arc of 180 degrees, the curve is unquestionably arch-shaped. If we extend this curve, until
1941 it is, say 270 degrees, it is still unquestionably arch-shaped,

and arches of such character are used in architecture. If we continue the curve through 360 degrees, I do not see that it ceases to be arch-shaped. But with either the helix or the spiral coil, the line is prolonged, so that instead of being 360 degrees, it is twice or thrice, or any number of times 360 degrees. And it seems to me that we must still consider it as arch-shaped; and, using the term in a technical sense, it might be spoken of as an arch, certainly without any greater extension of its meaning than when we apply the term "arch" to an inverted V.

239 X Q. Do you think the term "arch" is properly applicable to a form like the capital letter M with the angles rounded?

A. Such a figure, it seems to me, is properly included within the term "arch-shaped," and under certain circumstances might very properly be spoken of as an "arch." It is not, of course, for obvious reasons, a form used in architecture.

(Adjourned till 9 a. m., April 12, 1889.)

APRIL 12, 9.30 a. m.

240 X Q. Can you conceive of any form having the angles rounded that would not, in your opinion, be properly described as arc-shaped?

A. I do not think of any such form which might not without impropriety be thus described, though there are various such shapes which are not ordinarily designated as arches. Of course, this answer is not to be taken as having reference to the Sawyer and Man patent in suit, or to the shape of the carbon set forth in that patent?

1942 241 X Q. Do you think "arch-shaped" as used in the patent in suit is properly descriptive of every conceivable form having rounded angles.

A. I have not considered the range of applicability of this term as used in the Sawyer and Man patent.

242 X Q. Kindly do so, and answer my last question?

A. A question of this sort cannot of course be finally or properly answered without more study and thought than can be given in the brief time within which I suppose an answer is expected. I should suppose that a form which gave all the advantages of the horseshoe shape, and which possessed rounded angles would properly be described by that term as used in the patent.

243 X Q. Do you intend by your answer to question 17, to have it understood that in your opinion V-shaped conductors and conductors with rectangular bends are not conductors "of an arch or horseshoe shape," as stated in claim 1 of the patent in suit, or "having the form of an arch or loop," as stated in claim 4 of the patent in suit?

A. I meant by that answer to state that I did not understand Sawyer and Man in their patent to say that the V-shaped burner and burners with rectangular bends are full and complete equivalents for burners of the horseshoe form, since they regard this last form as having an advantage over the others.

244 X Q. Do you understand the words descriptive of the form of

the conductor in claims 1 and 4, as excluding V-shaped conductors and conductors with rectangular bends?

A. I have not considered the matter of the extreme limits of form which might properly be construed by authority competent to do it as coming within the scope of these claims. My individual judgement would be that if the forms to which you refer possessed all the advantages of the horseshoe form, they ought properly to be included within the scope of those claims.

245 X Q. Would a V-shaped carbon possess such advantages, or be the equivalent of the arc or horseshoe form? 1943

A. I should not think that it would possess all the advantages of the horseshoe shape.

246 X Q. If the V-shaped carbon had its angle rounded, would it be the equivalent of the arch-shaped conductor called for by claims 1 and 4?

A. It might be. One could tell better if he were referred to a particular lamp whose behavior he could study when in actual operation.

247 X Q. Referring to your answer to question 18, in what connection in the patent of Konn, No. 3809 of 1872, do you find the specific description of having the carbon "made thinner in the middle"?

A. In the patent referred to the patentee first describes the straight carbon which he uses in his lamp, and describes it as "composed of graphite or a composition of the usual description compressed or formed with a reduced diameter at or near its central part," referring to figure 7 in illustration. He afterwards goes on to describe a V-shaped carbon in which he says that the electric current passes "down one side and up the other side of the V, the light being formed at the angle at the bottom."

248 X Q. It is a fact, is it not, that specific description of reducing the diameter of the carbon at or near its central part, is given in connection with the straight carbon, and the straight carbon is shown in the drawing as having such construction?

A. The statement in words that the conductor is "formed with a reduced diameter at its central part" is naturally made with reference to the straight carbon, which is the first one described. The statement regarding the V-shaped carbon, that with it the light is "formed at the angle at the bottom" is in fact equally specific to one skilled in the art.

249 X Q. The straight carbons are clearly shown in the drawings of the Konn patent as having a reduced centre, are they not?

1944 A. The patentee gives very full and minute descriptions illustrated with numerous drawings—seven—of his lamp with straight carbons, and the patentee states that the straight stem is the form which he considers preferable. Those of his figures which are of such a nature as to indicate this peculiarity show it very plainly. The lamp with the V-shaped carbon which the inventor considers an inferior form is described very briefly and illustrated by only two figures neither of which is of such a nature that it needs to show or indeed ought to show this compression or reduction in size of the carbon, which naturally enough is not apparent in the figures.

250 X Q. Then it is a fact that the straight carbon is shown with reduced centre, and the V-shaped carbon is not so shown?—Kindly answer categorically, since I desire to make progress with the examination, and do not ask you for the reasons why such is the fact.

A. I am very sorry if I have needlessly consumed time in my answers, but I was unable to see how I could make them more brief, without danger of being misunderstood as to my views. I had supposed, however, that my previous answer was perfectly clear, and gave all of the information which your question asked for. I am glad, however, to answer categorically that in the Konn patent there are figures which illustrate the reduced section of the straight carbon, and that there is no figure which illustrates the reduced section of the V-shaped carbon.

251 X Q. What are the forms of incandescent lamps in which a straight carbon was employed, that you refer to in answer 14 as having seen?

A. Some of the earlier Bernstein lamps were those which I had in mind.

252 X Q. Were they lamps having tenuous, flexible carbons, like that of the Exhibit Defendant's Lamp put in evidence by the complainant?

1945 A. The lamp was for series lighting, and had a tubular carbon, in some respects like that shown in Complainant's Exhibit Bernstein Lamp, except that the carbon was straight, and, as nearly as I recollect, larger in diameter.

253 X Q. It was not a carbon of such tenuity as to have the high degree of flexibility that is possessed by the carbon in Complainant's Exhibit Defendant's Lamp?

A. It was a stout and comparatively short carbon and not tenuous like the carbon in defendant's lamp, and undoubtedly much less flexible.

254 X Q. Would not the filament of Complainant's Exhibit Defendant's Lamp readily bend and alter its shape as it expanded under increased temperature, even if made straight?

A. I have never seen such a lamp with the straight filament, and do not feel it at all certain as to what extent it could do this. Of course a tenuous filament would yield far more readily than a stiff one.

255 X Q. Have you any doubt that a filament of the extreme tenuity used in Complainant's Exhibit Defendant's Lamp would readily bend laterally without breaking under changes of temperature, even if in a straight form?

A. A filament as long as the one referred to would be, if straight, would undoubtedly bend with considerable readiness.

Adjourned to 2.10.

Adjourned to New York at office of Duncan, Curtis & Page, at 11 a. m., April 13, 1889.

1946 HOTEL BRUNSWICK, BOSTON, *April* 18, 1889.

Met pursuant to arrangement of counsel, and the cross-examination of Prof. CROSS herein by Mr. Dyer, was continued as follows, before William T. Farnham, special examiner:

Present: Edmund Wetmore, Esq., for complainant and R. N. Dyer, Esq., and H. D. Donnelly, Esq., for defendant.

256 X Q. The arch or loop form has as one advantage, has it not, that of permitting of an increased length of the conductor?

A. Of course with an arch form the length of conductor which can be contained within a globe of given size will be greater than if the conductor was straight.

257 X Q. This is also an advantage of a V-shaped conductor, is it not?

A. It is.

258 X Q. Could a straight carbon of the total length of that employed in Complainant's Exhibit Defendant's Lamp be placed within the globe of that lamp?

A. It could not.

259 X Q. In answer to interrogatory 23, you have stated that the Bernstein lamp employs a filament of woven silk. Do you consider silk a vegetable fibrous material?

A. It is a fibrous material but not vegetable in its nature.

260 X Q. Is it not a fact that the hydrocarbon treatment which you have referred to as described in the Sawyer-Man patent 211,262 may be carried to such an extent that the deposited carbon itself may be stripped from the core and used as the conductor?

A. I do not doubt that the carbon may be deposited to such a thickness that it will have a sufficient body to form of itself a conductor for an incandescent lamp. In saying this I do not of course express an opinion as to the practical value of a filament thus made.

261 X Q. What is the character of the carbon obtained by the hydrocarbon treatment?

1947 A. I have never seen any separated from the backing on which it is deposited. Apparently, however, it is firm and even in its texture, giving a lustre to the filament on which it is deposited.

262 X Q. Is it dense?

A. It is if it is deposited with sufficient thickness.

263 X Q. Does the deposited carbon of itself have a high or a low specific resistence?

A. I have never seen any measurement relating to this. I should suppose that if it were deposited in a thick layer such as we have been speaking of, its specific resistance would be lower than that of ordinary fibrous carbon.

264 X Q. Should you think it more or less hard and dense than gas-retort carbon?

A. I have never compared the two and cannot say.

265 X Q. Is the deposited carbon *per se* vegetable or fibrous or textile?

A. It is neither.

266 X Q. Would an incandescent conductor made from the deposited carbon have the properties which you consider requisite for the conductor of an incandescent lamp?

A. I have no experimental knowledge as to the action of such a conductor.

267 X Q. Does the fact that you have no experimental knowledge on this matter deter you from expressing an opinion upon it?

A. I always dislike to speculate unless I feel certain of my premises.

268 X Q. What experimental knowledge have you with regard to the use of gas-retort carbon for incandescent lighting?

A. Little, so far as my own individual experiments are concerned, but a good deal as shown by the experiments of others.

269 X Q. What experiments of others do you refer to?

1948 A. I had in mind the descriptions which are given in various patents and publications, such, for example, as the various exhibits in the present suit.

270 X Q. Have you any actual experimental knowledge yourself as to the use of gas carbon for incandescent electric lighting?

A. I do not recollect that I have ever tried to render gas carbon proper, incandescent by the passage of an electric current.

271 X Q. Have you any experimental knowledge as to the action of such wood carbon as is described in the Gaudoin French patent when employed for incandescent lighting?

A. I was not aware that these carbons had been used for incandescent lighting, and, if such is the case, I have no knowledge of the fact.

272 X Q. You, then, have no experimental knowledge as to the action of such a conductor when employed for the conductor of an incandescent lamp?

A. If you ask me whether I have ever tried or seen tried, the Gaudoin carbons for this purpose, my answer is that I have not. What I have said in my direct examination with regard to these carbons has been derived from the statements relating to them in the various publications in evidence, and from what seemed to me the immediate consequences of such statements.

273 X Q. But, as I understand you, not from actual experimental knowledge?

A. That is the case.

274 X Q. What is the difference between the character of the carbon, as a carbon, deposited by the hydrocarbon treatment, and the character of the carbon which Gaudoin adds to his wood carbon by impregnating the wooden objects before carbonization with the materials he mentions?

A. The expression in the original Gaudoin certificate of addition for April 7, 1877, is "carbone d'hydrogené." This is a technical chemical term of whose meaning I am not positive, but which
I suppose is a compound of carbon and hydrogen, of
1949 which the various substances mentioned are examples.
The nature of the deposited carbon will undoubtedly

differ to a greater or less extent with the substance from which it is deposited, with the rapidity at which deposition takes place, with the temperature at which deposition takes place and with the freedom of immediate complete decomposition and with the nature of the products of decomposition. With such a large variety of influencing circumstances, you will readily appreciate the difficulty of giving a brief and positive answer to your question. I should expect, however, that there would be very decided differences between the results of the hydrocarbon treatment and those of Gaudoin's process, not only in the structure of the conductor as a whole, but also in the peculiar qualities of the deposited carbon. Certainly the carbon that is obtained by the decomposition of sugar is quite different from that which is obtained by deposition from hydrocarbon vapor upon the filament of an incandescent lamp.

275 X Q. It is true, is it not, that in each case, that is, in the case of the hydrocarbon process described in Sawyer-Man patent No. 211,262 and in the case of the process of treatment of the wood carbon described in Gaudoin's French patent, the carbon deposited is one obtained by the decomposition by heat of a hydrocarbon?

A. Sawyer and Man, in their specification, speak of using a hydrocarbon liquid, which, properly speaking, is a liquid containing only hydrogen and carbon. I am not certain, however, that all of the substances which they mention are free from oxygen. In their claim they speak of the use of a carbon liquid, which I suppose would not exclude a liquid of which oxygen was a constituent part, provided that this was practically operative. I should suppose, however, that the presence of oxygen in the liquid used would be objectionable. Gaudoin, on the other hand, in his patent, though referring to hydrocarbons, also refers equally to various other substances which contain oxygen as well. In my answer to cross-interrogatory 294 I omitted to notice that certain 1950 of the substances mentioned by Gaudoin are not, properly speaking, hydrocarbons, since they contain oxygen. I will assume, however, that your question limits itself to the case of the Gaudoin carbon, when a hydrocarbon is used. In that case it is true that with the Gaudoin carbon, as with the carbon treated by Sawyer and Man's process, the deposited carbon is obtained by the decomposition of a hydrocarbon by heat. It does not, of course, follow from this fact that the properties of the deposited carbon in the two cases are identical.

Last sentence objected to as irresponsive and volunteered.

276 X Q. And in each case the deposited carbon is neither vegetable, fibrous nor textile?

A. It is certainly neither fibrous nor textile, nor could it even be what is understood by vegetable carbon. Of course, if a hydrocarbon of vegetable origin exists and were used, the deposited carbon would, in one sense, have a vegetable origin, and in this sense one might possibly apply to it the term vegetable carbon. I do not think, however, that there would be any justification for this use of language.

277 X Q. Would the Gaudoin deposited carbon be more hard, dense or compact than that deposited by the Sawyer-Man process?

A. I should think not. I should suppose it would be less homogeneous and comparatively uneven in structure.

278 X Q. Would it have a higher or lower specific resistance?

A. I know of no data which would enable one to be certain as to this matter. I should think it would depend very much upon the rapidity with which the carbon was deposited in the Sawyer-Man process, and upon the precise mode in which carbonization took place
with the Gaudoin carbon. I suppose that it would be easy
1951 to give to the deposited carbon by the Sawyer and Man process a specific resistance either lower or higher than that obtained with the Gaudoin process. In discussing this matter of specific resistance, however, it seems to me that there is a large element of ambiguity which enters your questions, and which necessarily, therefore, enters my replies thereto. The specific resistance of a substance is the resistance of a cube of that substance having unit surface and a thickness unity. Now, in the Gaudoin carbon I do not see how one can so isolate the deposited carbon from the carbon upon which it is deposited as to determine its specific resistance.

Adjourned till Friday, the 19th inst., at 9 a. m.

FRIDAY, *April* 19, 1889.

Met pursuant to adjournment.

Present: Counsel as before and the examination of Prof. CROSS was continued as follows:

279 X Q. Is there any radical difference in the specific resistance of the carbon deposited in each of the two cases assumed in the last few questions?

Before answering this question, witness says:

I should like to say with regard to my answer to cross-question 275, that since the last session I have consulted with several chemists as to the term "carbone d'hydrogené." I am informed that this is not an expression which would be used by one conversant with chemistry, but it undoubtedly means a hydrocarbon as I had supposed. I find also in relation to the substances mentioned by Sawyer and Man in their hydrocarbon patent under consideration, that turpentine is a true hydrocarbon, but that beeswax contains oxygen.

Witness continues in answer to question 279:

A. I cannot say whether there is or is not; that is, if
1952 by specific resistance you mean the specific resistance of a
very small particle of the carbon. If by specific resistance you mean the resistance of the substance as it actually lies within and upon the treated carbon, I should think that there would be a difference, and not merely a difference between the Sawyer and Man deposited carbon and the deposited carbon in the Gaudoin process, but also a difference with the Gaudoin carbon according to the substances used and the precise preparation. This is what would

naturally be expected from the great difference in the two processes whereby what we have called "deposited carbon" is obtained.

280 X Q. Then in each case, that is the Gaudoin French patent and the Sawyer and Man patent No. 211,262, hydrocarbons, properly speaking, are mentioned as well as hydrocarbon compounds containing oxygen?

A. Taken literally, this is true, but I think there is quite a distinct difference between them. Sawyer and Man propose distinctly to make use of a hydrocarbon, and simply mention the substance beeswax which contains oxygen. Gaudoin, on the other hand, distinctly proposes to use any substance containing carbon, whether it is really a hydrocarbon or not, and merely enumerates "any hydrocarbon" among a large number of substances. That is, there is nothing to indicate that Gaudoin considered a hydrocarbon as in any way preferable to any one of the other substances which he mentions.

281 X Q. Aside from what you consider the order of importance in which the two classes of materials are named in the two patents, it is a fact, is it not, that they both mentioned hydrocarbon, properly speaking, and hydrocarbon which contains oxygen?

A. That is the case.

282 X Q. In your answer to question 33 you state:

"It seems to me that the use of the glass plate or stopper is entirely novel with Messrs. Sawyer and Man."

1953 In the assumption upon which this statement is based do you omit the general knowledge as to the use of such a plate or stopper in pneumatic apparatus?

A. I was perfectly familiar with the use of such a device in pneumatic apparatus. I did not consider it as material in its bearing upon the use of such a plate or stopper in an incandescent lamp.

283 X Q In answer to question 34, you state:

"It is quite true that any lamp possessing such a low resistance" (as that of the patent in suit) "would not be suited for use over considerable districts in a parallel system of illumination; but on the other hand it is in this respect exactly the kind of lamp that is wanted for use in a series system, and in fact lamps of low resistance and adapted to run in series are now customarily made and employed."

How long have such lamps been customarily made and employed?

A. I do not recall when I first knew of series incandescent lamps being used commercially and to any extent, but it is certainly a good many years. I think that such lamps have been constructed from the very beginning of the art of incandescent lighting. There are, of course, obvious reasons why in the earliest days of incandescent lighting general attention was turned from the use of such incandescent lamps in series to the use of incandescent lamps of higher resistence and in parallel.

284 X Q. Is it not a fact that incandescent lamps of low resistance

run in series have only been customarily made and employed within the last three or four years?

A. I am confident that I am correct in my recollection that incandescent lamps have been run in series for a much longer time than you mention. The resistances of these lamps were greater or less accordingly to the circumstances under which they were to be operated.

1954 285 X Q. Were they so "customarily made and employed" before January 9, 1880?

A. Not so far as I know. The conditions of electric lighting at that time do not seem to have been such as to call for them. The date that you mention was a very early one in the history of the art of commercial electric lighting.

286 X Q. At that date it is a fact, is it not, the art of commercial incandescent electric lighting had developed only in the direction of high resistance lamps adapted to be run in parallel?

A. The use of incandescent lamps in parallel was naturally the first to develop, and at the date you mention, so far as I recollect, the parallel system of distribution was the one ordinarily employed. The lamps used had various resistances, running perhaps from twenty ohms upwards. I think, however, that even at the early date you mention lamps of low resistance were made and used, although this may possibly not have been the case until a year or two later. I should wish to refresh my memory by contemporaneous data before being positive.

287 X Q. Complainant's Exhibit Defendant's Lamp is a high-resistance lamp adapted for use in parallel, is it not?

A. It is, unquestionably.

288 X Q. If no better styles of incandescent lamp existed, how poor a lamp would, in your opinion, have a distinct commercial value?

A. I do not know of any scale of excellence whereby I could rank the different incandescent lamps of history or imagination, or even if I had such a scale where its zero point would lie, and for this reason I am unable to give a satisfactory answer to the question.

289 X Q. Do you think an incandescent lamp having a life of one hour would have a distinct commercial value if no better style of incandescent lamp existed?

A. There would not be a large demand for such lamps 1955 commercially, but it is possible that such a lamp might have its use in special cases. Of course, such a lamp could not compete for general purposes with other illuminants.

290 X Q. But for soms special purposes it might have a distinct commercial value, as I understand you?

A. It is quite possible that it might.

291 X Q. How were the facts known which you referred to in answer to question 40?

A. I suppose that they had become known as all such facts become known, from observation and study.

292 X Q. Where are they disclosed; by what specific publications?

A. The general matters of structure will, I think, be found in the various text books of botany of the date. The methods of carbonization are described in various of the exhibits in evidence in this case.

293 X Q. Where was the knowledge published "that certain woods were fitted and certain others unfitted to produce a carbon of even and dense structure"?

A. In various places. Thus, in connection with the early history of the electric arc it became known that there was a marked difference between charcoal made from different kinds of wood. So also in the manufacture of charcoal for gunpowder and like purposes there had been much research.

294 X Q. Did the knowledge extend to the evenness and density of the resulting carbon with reference to its electrical qualities, resistance and conductivity?

A. There was considerable knowledge regarding this matter, though, of course, those especial peculiarities which would indicate that one particular wood was better than another particular wood had not been thoroughly studied with regard to the use of such a carbon in an incandescent light.

295 X Q. Where was the knowledge published showing the desirability of avoiding a cutting across the fibre and of selecting a wood possessing fibres which were parallel?

1956 A. I did not have in mind any specific publications when I made this statement. It seemed to me that the exercise of ordinary good judgment would indicate this.

Adjourned till 2 o'clock.

Resumed after adjournment.

296 X Q. You are aware of the fact, are you not, that the patent of Mr. Edison, No. 248,417, referred to by you in answer 39, describes a method of cutting the carbon from wood in which the carbon loop is cut across the fibres of the wood for at least a portion of its length?

A. That is my understanding of the description.

297 X Q. In the lamp structure of the patent in suit the joint between the plate *y* and the flange *x* of the globe, the joint between the tubular bolts and the plate *y*, and the joint between the tubular bolts and the covering caps are all points at which there would be liability to leakage?

A. That is true, so that especial care must be taken to prevent such leakage.

298 X Q. In answer to question 36 you have stated in substance that there are advantages in using the arch shape with carbon which are not possessed by the use of that form with metal conductors. Is it your opinion that those advantages are present with carbon generally or only with some special character of carbon?

A. I should think that there would be an advantage in using the arch-shaped conductor with any kind of carbon, since this form allows the material to expand or contract without producing the excessive strain which would occur if it were straight. It is very possible, however, that with a brittle carbon, such as gas carbon, even the use of the horseshoe form might not be sufficient to preserve it from rupture.

1957 299 X Q. Then, as I understand you, the arch form in your opinion is even more necessary with a conductor of brittle carbon, such as gas-retort carbon, than with a conductor of fibrous carbon?

A. I had not intended to be understood thus, and do not feel at all ready to make a broad general statement of this kind.

300 X Q. The advantages of the arch-shape would at least be equally important with the gas or hard carbon conductor?

A. It would seem so at first sight, assuming that the gas carbon is more brittle in all cases than the fibrous carbon. I do not feel at all positive, however, that the advantage of the shape with any and every kind of fibrous carbon is necessarily greater than with gas carbon, because there are various circumstances that come into play regarding which I have no data in mind which settle the matter beyond question.

301 X Q. Do you know of any paper which has a thickness sufficient after the shrinkage produced by carbonization to make a carbon of the thickness shown in figure 4 of the patent in suit?

A. I cannot say positively, but I should think that heavy paper board, mill-board I think it is called, or something of that kind would give this result.

302 X Q. How thick is the mill-board you refer to, and what is it used for?

A. I think I have seen it a tenth of an inch thick or more. I don't know exactly, but my impression is, that it is frequently used for the covers of books in binding.

303 X Q. Is it not a fact that Complainant's Exhibit Defendant's Lamp has a hair-like filament such as you had in mind in answering questions 53 and 54?

A. It is.

304 X Q. You have stated, in answer 62, that the word "arc," in the fourth claim of the original specification of the patent in suit, "means simply strip." Is not that an unusual meaning of the word?

1958 A. It is.

305 X Q. What is its usual meaning?

A. A portion of a curve, or a curved strip.

306 X Q. Is it not derived from the same root as the word arch, viz: *arcus*, a bow?

A. It is.

307 X Q. Is plumbago a vegetable or fibrous or textile carbon?

A. It is not, it is a mineral.

308 X Q. Has it the qualities as a carbon which make carbon from fibrous vegetable material peculiarly adapted for incandescent lighting?

A. It has not.

309 X Q. Do you know of any commercially used incandescent

lamp made with joints in its chamber such as those shown and described in the patent in suit?

A. I do not.

310 X Q. Do you agree with the following statements made by Prof. Edwin J. Houston, who testified as an expert for complainant in the suit brought by the same complainant upon the same patent as involved in this controversy against the Edison Electric Light Co. and Thomas A. Edison, defendants, and now pending in the southern district of New York?

Answer to cross-Q. 69:

"I think that in the manufacture of incandescent lamps the general custom in the art at the present time is to obtain the joint by the fusion of the glass, and not by the use of a current."

And the last sentence of answer to cross-Q. 73:

"As far as I am aware the incandescent lamps in general use are in accordance with the method in which the joints are fused together and not cemented."

Objected to as immaterial.

A. I do.

1959 311 X Q. Do you agree with the following opinion expressed by Prof. Houston in the same case in answer to cross-question 123 in comparing the Edison lamp with that of the Sawyer-Man patent 205,144?

"Or to summarize, I acknowledge that the following differences do exist in the two lamps in question, and I have endeavored to point out to counsel in previous answers that I am aware of the existence of such facts, namely: that we have in the case of the Edison lamp as contrasted with that of the lamp shown in Fig. 1 of 205,144 a high vacuum as contrasted with a low vacuum of an inert gas; that we have in the one a high resistance as against a low resistance in the other; that we have a lamp chamber made of two separate pieces of glass subsequently fused together, as against a lamp chamber made of two pieces of glass subsequently fitted together; that we have in the case of 205,144, which was presumably a lamp of high candle power, more heat generated than in the case of the Edison lamp exhibit; and that in 205,144 means are provided to prevent this heat from injuring the atmosphere left in the lamp chamber."

Same objection.

A. The differences between the two lamps referred to by Prof. Houston undoubtedly exist.

312 X Q. Do you agree with the opinion expressed by Prof. Houston as shown by cross-Q. 292 and answer which are as follows:

"292 X Q. I understand you to have testified that you regard within the meaning of the specification the word 'arc' as intended to cover these various shapes including the V-shaper burner. What I would like to know is whether you consider the word 'arc' as an

accurate term with which to describe a V-shaped burner or
1960 the burner shown in Defendant's Exhibit Arc with Curvilinear Bends, December 28, 1886"?

"A. I am of the opinion that the V-shaped burner would equally come under the general meaning of the word arc as would the three drawings which I have made and which I mark respectively 'arc with rectangular bends,' 'arc with curvilinear bends' and 'arch conductor' of December 28, 1886, since a burner terminated in parallel wires and joined at their upper ends by a 'V'-shaped extension thereof would also, like the drawings referred to, pass through an angular divergence of 180 degrees, as will be seen by referring to the drawing which I now produce"—

Referring to the three exhibits sketches which are referred to in the question and answer which are as follows:

Defendant's Exhibit Arc with Cuvilinear Bends, Dec. 28, 1886.
Defendant's Exhibit Arch Conductor, Dec. 28, 1886.
Defendant's Exhibit V-shaped Burner, Dec. 28, 1886.

Same objection.

A. I do not think I should have answered the question precisely as Prof. Houston answered it.

313 X Q. Do you agree with the opinion expressed by Prof. Houston in the same case as shown by cross-question 329 and answer, which are as follows:

"329 X Q. You have stated in your examination that the inventors incidentally considered the arch form as new with them. Were not the inventors mistaken in that opinion?

A. If it be true that the inventors thought that the arch form had not heretofore been employed when made of carbon, then
1961 they were wrong, since the patent 3809 of 1872 to Konn anticipated such general form."

Same objection.

A. I do not think that the V-shaped conductor of Konn is the equivalent of the arch-shaped carbon of Sawyer and Man.

314 X Q. You have stated, in substance, in answer to question 44, that the process of making a practical conductor for an incandescent lamp was well known prior to the application for the patent in suit. How widely was such process known?

A. I do not think that your question fairly represents my answer to interrogatory 44. In that answer, I endeavored to show what would have been done in the light of existing knowledge by one wishing to follow out the directions of the Sawyer and Man patent, and construct an incandescent lamp. I certainly did not state therein that "the process of making a practical conductor for an incandescent lamp was well known prior to the application for the patent in suit," but I did endeavor to show, and I think with success, that the state of knowledge was such that with the directions given by Sawyer and Man an incandescent lamp could be constructed by one skilled in the art, and without the exercise of invention.

315 X Q. In justification of your position that no especial description as to the carbonization was required in the patent in suit in order to enable one skilled in the art to produce a practical carbon conductor for incandescent lamps, you state, in answer 44, that—

"The subject of carbonization had been carefully studied, and the methods whereby thorough, uniform and complete carbonization could be secured were perfectly well known to those skilled in the art."

To what art did you refer?

1962 A. The art of carbonizing woods and other fibre. Illustrations of the state of this art are found in the papers of Violette and Sidot which are exhibits in the present suit.

316 X Q. Was the subject also well understood by scientific men and electricians such as yourself?

A. It was well understood by scientific men. I had not considered the subject of carbonization myself at the date of the application for the patent, and therefore was not particularly well informed regarding it. I do not think, however, that I should have found difficulty in putting the invention under consideration into practice.

317 X Q. That is, you think that you were sufficiently well acquainted with the art as to carbonization to enable you to do it or at least to direct workmen how to do it?

A. Of course if I had proposed to make such a lamp which involved the carbonization of paper or other similar material, I should have made inquiry of those possessing a technical knowledge of carbonization as to the best process to follow, just as in following out the directions of any patent to-day, I should inquire as to the technical details of any portion of the process outside of my immediate specialty. If, for example, I wish to make an Edison lamp to-day, following out the directions in any one of Mr. Edison's patents, I should make inquiry as to the best method of connecting the filament to the leading wires, the best form of air pump to use in practice, etc.

Adjourned to office of Messrs. Duncan, Curtis & Page, New York city, to meet to-morrow (Saturday) morning at 11 o'clock.

NEW YORK, *April* 20, 1889.

Met pursuant to adjournment.

Present: Mr. Curtis and Mr. Wetmore for complainant and Mr. Dyer and Mr. Donnelly for defendant, and the examination of Prof. CROSS was continued as follows:

318 X Q. Outside of details of manipulation, did you yourself at the date of the application for the patent in suit understand the perfection to which the art of carbonization had been carried? 1963

A. It is difficult for me to say specifically and in detail what I personally did or did not know regarding carbonization at the date mentioned in the question, since I had then had no occasion to consider any question involving the practice of this art. I am certain, however, that I was well aware that the art of carbonization had been carried in certain directions to a state of great perfection.

319 X Q. Were you better acquainted with the matter in 1881?

A. I do not doubt that I was.

320 X Q. Are you better acquainted with it now than you were in 1881?

A. I am.

321 X Q. Were you not at one time retained as an expert by the Edison Electric Light Co.?

A. I was; I accepted a retainer from them for a single year.

322 X Q. What time did the retainer cover?

A. I don't remember the date, but it must have been about 1881.

323 X Q. During the time of your employment by that company did you make an examination of patents and publications relating to electric lighting and give an opinion to the company upon the matters to which the examination was directed?

A. I did make an examination of certain patents and publications to which they directed my attention. I do not think that I made any extended research outside of these, although I doubtless made reference to such books as I was especially familiar with relating to the subject in question.

324 X Q. Are the two letters I hand you, dated June 23, 1881, and June 24, 1881, and addressed to F. H. Betts, Esq., the report which you made as the result of the examination referred to in your last answer?

1964 A. There is no doubt that such is the case. I recollect them perfectly.

325 X Q. What relation did Mr. Betts hold to the Edison Electric Light Co. at that time, if you know?

A. I understood that Mr. Betts was of counsel for the Edison Company.

The letters referred to are offered in evidence by counsel for defendant, and the same are marked "Defendant's Exhibit Prof. Cross' Report of 1881, April 20, 1889 (No. 1 and No. 2).

Said exhibits objected to as immaterial.

Redirect examination by Mr. WETMORE:

326 R. D. Q. I call your attention again to the English patent of Shepard, No. 13302 of 1850, and particularly to section VI of the specification, page 9, and figure 10 therein referred to. Please examine said drawing and description, and state how far down the little charcoal cylinder the copper tube comes, and what you now find to be the effect in the operation of the lamp of said copper tube?

A. On reading this patent again and more carefully, I find that there is a misapprehension of the statement referred to in the 124th cross-question, which misapprehension also exists in my answer to that question. This misunderstanding, on my part at least, came from a grammatical ambiguity in a statement regarding the cone D and the cylinder E. The statement is that—

"The other polar wire comes out under the lower end of this tube at about one centimetre (three-eighths of an inch) distance from its extremity, and terminates in a little cone, D, of prepared charcoal or coke, and against the top of which the little charcoal cylinder E rests, which, when the current is established, becomes incandescent, and remains in this state a very long time, because the small
1965 portions which are consumed are continually replaced by a portion of the cylinder which the metal presser forces onto the top of the cone."

At first sight on reading this it would seem as though the word "which" after the expression "against the top of which the little charcoal cylinder E rests" refers to the charcoal cylinder E. This was the assumption apparently made in cross-question 124 and which I made in my answer thereto. This assumption, however, is erroneous as immediately appears from an examination of Fig. 10 of the drawings which shows the device in question. The copper tube C is shown as descending sufficiently far to entirely cover the carbon cylinder, from which therefore, except at the surface of contact of the cone with it, no light could be radiated, and even from this surface of contact no light could be radiated except through the lower half of the globe. From this therefore it appears that it is the cone D, and not the cylinder E, which becomes incandescent. And this is quite consistent with the statement made in the specification, if we assume the word "which" to refer to the cone, as I have suggested. The patent goes on further to say that the incandescent portion, which I understand to be the cone D, "remains in that state (*i. e.*, incandescence) a very long time, because the small portions which are consumed are continually replaced by a portion of the cylinder which the metal presser forces onto the top of the cone."

By this I understand the patentee to state that, as small portions of the cone are consumed the cylinder moves downward under the "metal presser" so as always to keep a contact between the cylinder and cone, thus replacing the portions of the cone which are burned away by the lower end of the cylinder. This gives an excellent description of the operation of an arc incandescent lamp.

327 X Q. In 132 X Q. your attention is called to an incandescent form of the Greener and Staite lamp described at page 3 of the patent beginning at line 33. What is the kind of carbon
1966 referred to in that patent and which constitutes the hollow cylinder between the two platinum cones in the part of the description to which your attention was so called?

A. The same kind of carbon which Greener and Staite refer to in the other portions of their patent, the form which they prefer being carbon prepared from coke.

328 R. D. Q. For what sort of a lamp is the carbon prepared from powdered charcoal and pressed into shape and treated as described on page 2, lines 32 and following of said patent, suitable?

A. It is especially suitable for use in arc lighting or in arc incandescent lighting.

329 R. D. Q. Is it a carbon made from fibrous or textile material, or does it fall under the class of hard carbon?

A. It is a hard carbon, or at least is intended to possess the peculiarities of such a carbon.

330 R. D.—. In 137 cross-Q. you were asked the foundation for your statement that Foucault suggested the use of gas-retort carbon for arc-light electrodes about 1845. Have you since your cross-examination found any publication which enables you to verify your statement, if so, will you please produce the same?

A. What I think is the original statement of Foucault regarding this matter is found in Comptes Rendus for 1844, vol. 18, page 751, in a paper by Fizeau and Foucault, in which they say:

"L'un de nous, M. Foucault, a atteint ce but par l'emploi du charbon provenant de la distillation de la houille; ce charbon permet d'obtenir à l'air libre une lumière fixe et surtout durable, à cause de la lenteur de sa combustion; toutes nos experiénces out été faites avec ce charbon"—

which I translate as follows:

One of us, Mons. Foucault, has reached this end by the employment of the carbon resulting from the distillation of coal; this carbon allows us to obtain in the open air a light which is fixed and especially durable, because of the slowness of its combustion; 1967 all our experiments have been made with this carbon."

Also on page 861 of the same volume, in a second paper by the same authors, I find this statement:

"Le charbon très-dense qui provient de la distillation de la houille, et que nous avons employé, a des caractères physiques qui le rapprochment de l'espéce minerale appelée anthracite; en examinant, après les expèriences d'incandescence, le charbon transporté au pôle négatif et l'extrèmité du pole positif lui-même, nous avons remarqué que ses charactères physiques sont alors changés. Ce charbon est mou, traçant; sa surface, étant, frottée, devient d'untgris plombé métallique. Ces caractères l'assimilent complétement à l'espèce minérale appelée graphite; cette modification se fait très rapidement, et s'obtient également avec d'autres especes de charbons conducteurs. Il suffit de promener l'arc lumineux sur la *sur la* surface d'une des pôles de charbon pour que cette surface soit à l'instant revêtue d'une couche de graphite.

Cette formation de graphite, sous l'influence d'une température tres élevée, nous semble devoir jouer un rôle important dans l'étude des masses minérales où se recontre si fréquemment cette variété de charbon."

This I translate as follows:

"The very dense carbon resulting from the distillation of coal which we have employed, has physical characteristics which relate it to that kind of mineral called anthracite; on examining (after the experiments with incandescence) the carbon which has been carried from the negative pole to the end of the positive pole, we observed that its physical characters have been changed.

This carbon is soft and makes a mark; on being rubbed its surface appears of a metallic lead gray. This modification takes 1968 place very rapidly and occurs equally with other kinds of conducting carbons. It is sufficient to produce the luminous arc on the surface of one of the carbon electrodes to instantaneously cover this surface with a layer of graphite.

This formation of graphite under the influence of a very high temperature ought to have an important bearing on the study of the mineral masses which one so frequently meets in this kind of carbon."

The parts of the work quoted in the answer are offered in evidence and marked Complainant's Exhibit Extract from Comptes Rendus of 1844, W. T. F., sp'l ex'r, April 20, 1889.

331 R. D. Q. In cross-question 201 your attention is called to the process of preparing carbons described in the Slater and Watson and Harrison English patents. Suppose those processes to be carried out, what kind of carbon would be the result in respect to its being hard carbon or otherwise?

A. It would be hard carbon similar in its characteristics to that used by Foucault.

332 R. D. Q. Is there any substance enumerated in the Gaudoin patent or the additions thereto which if treated by the process therein described would result in the same thing, in structure and properties, as the fibrous or textile conductor of the patent in suit, if such conductor in the course of its manufacture was treated by the Sawyer and Man hydrocarbon process?

A. There is not. The endeavor of that patent is to produce a hard carbon, equally hard throughout. The aim of the hydrocarbon treatment as applied to a fibrous conductor is to equalize its resistance and to heal imperfections, the carbon being deposited precisely where it is needed and not elsewhere, so that its deposition is greater at those points where it is needed most. No such operation is intended or is possible with the Gaudoin carbons, and in that process there will be secured either an appoximate even- 1969 ness of deposition of the carbon or more likely an unevenness which would be quite as likely to give an excessive deposition where it would do harm in an incandescent lamp as where it would do good.

333 Re. D. Q. Please state generally, so far as you remember, what patents or publications you examined as the basis of your opinion to the Edison Co., which has just been put in evidence, and particularly state whether you had or had not then examined the Lane-Fox patent, in evidence in this case.

A. I must answer this question wholly from memory as my various memoranda are in Boston. I consulted chiefly, if not entirely, certain patents and publications of which a list was sent me by the

Edison Company. I have no recollection of reading the Lane-Fox patents till within a very few weeks.

Adjourned for lunch.
Resumed after lunch.

334 Re. D. Q. What is the object and effect of the glass plate stopper used in air pumps and other similar pneumatic apparatus?

A. The object of using the glass plate in an air pump or similar apparatus instead of the brass plate is to avoid corrosion of the plate in case any substances are used which might cause this. The metal plate with an air pump is equally efficient with a glass plate so far as holding a vacuum is concerned. So far as heating is concerned, it is desirable to avoid the use of a glass plate with an air pump from the danger of cracking it.

Recross-examination:

335 R. C. Q. With reference to the Shepard English patent, if the lamp shown in figure 10 were hung overhead as electric lamps usually are, would not a part of the lower end of the charcoal cylinder E be disclosed to sight?

1970 A. I suppose a trifling portion of it might be seen from certain positions, but it would be utterly ineffective as an illuminant, even though rendered incandescent, since the light would be cut off for more than 180 degrees by the tube, and from a very considerable angle below, by the shadow of the cone. Such a structure so operated would be manifestly absurd.

All the answer after the first thirteen words objected to as irresponsive and volunteered.

336 R. C. Q. If the cone D of the Shepherd patent is consumed and the charcoal pencil E fed down, would not the charcoal pencil E be further disclosed to sight?

A. It would, undoubtedly.

337 R. C. Q. If the cone is to be consumed, and not the pencil, does it occur to you that the pencil is made unnecessarily long to take up the consumption of the cone?

A. Of course there would be no necessity of using so long a pencil simply to take up the consumption of the cone, but, with such a construction as is shown, it would be very natural to use a pencil of moderate length like that shown in the figure. I do not imagine that the figure is a working drawing of the device.

338 R. C. Q. So you think to take up a consumption in extent about three-eighths of an inch, a pencil of an inch in length would naturally be used; that is, more than double the length required would be used?

A. I think that if one were making a model experimental lamp he would be very likely to do this, taking a pencil of such length as he happened to have, or breaking it off of a moderate length without very much regard to the minimum possible length. I know that I myself am likely to proceed in this way in making experimental devices, and I think that this is very common under such circumstances. If a device of this sort were made commercially, very likely the carbon cylinder would have been made shorter.

339 R. C. Q. If the cone is to be consumed and not the
1971 pencil, what will happen when the apex of the cone is worn
off, and the cross-section of the cone at the contact increased so as to be larger than the pencil?

A. I should suppose that the operativeness of the device as an arc incandescent lamp would cease long before this condition was reached. In any event the end surface of the cone, and probably the lower end of the cylinder would have become very rough so that they would both wear away. Very likely under these circumstances the cylinder might wear more than the cone, and I suppose that on the whole it would.

340 R. C. Q. Is it not the usual construction of an arc incandescent lamp to have the pencil which is consumed by being rendered incandescent at the point of contact of uniform diameter and fed forward as it is consumed?

A. I think that such cylinders are frequently pointed at the ends. They are usually fed forward as consumed.

341 R. C. Q. Aside from the pointing of the extreme end, the consumed pencils are of uniform diameter, are they not?

A. They often are. The pointing, however, may be quite acute.

342 R. C. Q. But however acute the point, the pencil has a body of uniform diameter extending back of the point?

A. Beyond the junction with the cone which ends in the point, the pencils have usually been, like those used in arc lighting, of uniform diameter.

343. R. C. Q. With reference to your answer to cross 339, at what point and why would the device cease to be operative?

A. I cannot say at what particular point this would happen, but the two flattened surfaces which would presumably result, are not well suited to the maintenance of such a light, so that I should expect irregularities to occur, so that difficulty would be found in keeping up the operation of the lamp without modifications of the current, and perhaps with them.

344 R. C. Q. But this would occur before the cone wears enough to prevent a cross-section greater than the pencil, as I understand you?

1972 A. I should expect this. Of course my replies are hypothetical, as I have never tried, or seen tried, such a lamp.

345 R. C. Q. Then you think that a pencil an inch long would naturally be provided to take up a wear of about an eighth of an inch?

A. You have evidently mistaken the sense in which I used the word "naturally" and perhaps my meaning was not made altogether clear. What I intended to convey was simply that, in my opinion, if a person were making such a lamp experimentally, or making a sketch of such a lamp, he would be very likely to break off a carbon pencil of greater length than was absolutely necessary, since it would be, for one thing, easier to handle in the actual lamp, and its position and purpose more evident in the drawing. The probability is that under the circumstances assumed, he would not give very much attention to the length absolutely needed, except that he would be sure to have it long enough. Nothing is more common in such sketches as are found in patents and illustrative diagrams generally, than to draw the various parts of quite different dimensions from those which would be best suited to their effective operation is actual practice.

346 R. C. Q. Then you do not consider it significant in determining which of the two elements D and E is intended to become incandescent and be consumed in the operation of the lamp, that the operative length of one element, viz: D is only about an eighth of an inch while the operative length of the other element E is about an inch?

A. I do not consider it as at all conclusive.

347 R. C. Q. When the cone D burns down to a larger area, is the arc suppressed by the additional area of contact?

A. Not necessarily, but it is desirable to have the contact
1973 area small that the apparatus may work at its best.

(Signed) CHAS. R. CROSS.

Subscribed and sworn to before me this 20th day of April, A. D. 1889.

WM. T. FARNHAM,
Special Examiner and Notary Public for the County and State of New York.

Certificate of examination to the above deposition of Prof. Cross is hereby waived by consent of counsel.

1974 NEW YORK, *April* 10, 1889.

Met pursuant to arrangement of counsel. Present, L. E. Curtis, Esq., for complainant and W. K. Griffin, Esq., for defendant.

Testimony of Henry Morton.

HENRY MORTON, being called on behalf of complainant and duly sworn, testifies as follows:

1 Q. What is your name, age, residence and occupation?

A. Henry Morton, 52 years of age; I reside at Hoboken, N. J.; am president of the Stevens Institute of Technology at that place.

2 Q. What knowledge have you of the science of electricity and its application to the various useful arts and what familiarity have you with electrical instruments and apparatus and particularly those used in the art of electric lighting?

A. For more than twenty-five years I have had in my possession and almost constant use a great variety of electrical apparatus and during this same period have given lectures to my classes on the science of electricity, and on the use and application of such electrical apparatus. At the time that electric lighting began to assume commercial importance I was a member of the United States light-house board and as chairman of the committee on scientific tests of that body I conducted a series of tests of various forms of apparatus employed in electric lighting, the results of which were embodied in reports published by the light-house board in 1879 and 1880. About the same time, and continuously thereafter to the present date, I have conducted numerous tests on the various forms of dynamo-electric machines, electric lamps, storage batteries and other apparatus used in the various systems of commercial electric lighting.

3 Q. What familiarity have you with the lamps and other devices used for incandescent lighting?

A. I have examined and tested a great number and
1975 variety of incandescent electric lamps, including most of
those which are in commercial use at the present day. I have also repeatedly witnessed the construction of these lamps at various factories where they are manufactured in quantities.

4 Q. Have you read complainant's patent in suit—letters patent No. 317,676, granted May 12th, 1885, to the Electro-Dynamic Light Co., of New York, as assignee of William Edward Sawyer and Albon Man, and do you understand the same?

A. I have carefully read this patent and I believe that I understand it.

5 Q. Have you read the depositions of Prof. Cyrus F. Brackett, Prof. Geo. F. Barker, Prof. Wm. P. Wilson and Mr. Edison who have testified as experts in this case?

A. I have.

6 Q. Do you agree with the opinions expressed by defendant's experts, or some of them, that there is not a sufficient description in the specification of the patent in suit as to the character of the fibrous material to be used for the burner, its selection, its preparation for carbonization and its carbonization to enable others generally skilled in the art as it existed prior to 1880 to produce a practically operative incandescent conductor without experiment? I call your attention particularly to Prof. Brackett's answers to questions 16 to 19 inclusive, cross-questions 55 to 57 inclusive, to Prof. Barker's answers to questions 22 to 27 inclusive, Prof. Wilson's answers to questions 5 to 29 inclusive, and Mr. Edison's answers to questions 412 to 435 inclusive, 439 to 441, 457 to 464½ inclusive. Please give your reasons for any opinion you may express?

A. I do not at all agree with the opinions expressed by the gentlemen named, and I think I can best make clear my reasons for coming to a different conclusion from theirs, by pointing out, in the first place, what I find in the patent referred to, as to the character of the fibrous material to be used for the burner, its selection, preparation and its carbonization.

1976 In the first place, at line 25th of the first page of the patent, I find these words:

"An incandescent conductor of carbon, made from a vegetable fibrous material."

At line 76 of the first page I find as follows:

"In the practice of our invention we have made use of carbonized paper, and also wood carbon. We have also used such conductors or burners of various shapes * * * but we prefer the arch shape."

At line 87 of the first page I find as follows:

"No especial description of making the illuminating carbon conductors, described in this specification, and making the subject-matter of this improvement is thought necessary."

At line 21, page 2d, I find as follows:

"The advantages resulting from the manufacture of the carbon from vegetable fibrous or textile material instead of mineral or gas carbon, are many."

Again, at line 45 of the second page, I find the first claim expressed as follows:

"An incandescing conductor for an electric lamp, of carbonized fibrous or textile material, and of an arch or horseshoe shape, substantially as hereinbefore set forth."

I also find in the second claim, the expression "carbonized fibrous material." In the 3d claim, the expression "carbonized paper," and in the 4th claim, the expression "consisting of carbon made from a fibrous or textile material, having the form of an arch or loop."

With these quoted passages either taken by themselves or in connection with their context before him, it seems to me that one skilled in the art would have abundantly sufficient instruction as to the material to be selected, its preparation and carbonization. The prominent features pointed out by the quoted passages are, that the incandescent conductor is to be made of a fibrous vegetable 1977 or textile material in the form of an arch or loop and carbonized so as to be converted into such a conducting material as would be useful in an incandescent electric lamp. The instruction that the material was to be at the outset of fibrous vegetable or textile character, would at once instruct any one desiring to carry out the invention that he should employ preferably, or as the most natural thing, such textile material as exists in the form of cotton or linen thread or vegetable fibre of any other sort which had been reduced to a textile shape, that is, brought into a condition fitting it for weaving or other method of producing a textile fabric. The most natural thing or material for the workman to employ would thus be the ordinary cotton or linen thread of commerce of the better sort, that is, such as consisted of fine vegetable fibre and was of uniform cross-section. Any one having the most ordinary knowledge of the art would be, of course, aware that irregularities in the material or lack of uniformity in cross-section, would be highly injurious because they would lead to irregularities in the conducting power of the resulting carbon conductor, which would be most injurious, if not fatal, to its utility. Next to cotton and linen thread, the workman desiring to carry out the instructions of this patent would, it seems to me, naturally consider such materials as are used in the weaving of baskets and other articles, and which consist of strips cut from various forms of grass or reeds and especially from bamboo, because these would be fibrous vegetable sustances already reduced to the form of textile material, that is to a shape adapting them to the process of weaving in the manufacture of baskets or the like. If the workman were to go further than this, as he might do were it his object to produce incandescent conductors of a larger size, he might then seek among the various woods those which most resembled in their structure the fibrous and textile materials which had naturally presented themselves to him in the first instance. In the next place, having in view the statement that the conductor was to be used in an arch form, he would, as a matter of course, give the material this arched 1978 form previous to carbonizing it, since he would certainly know that it would be much easier to bend or curve any of these materials into the arched form while they were in their fibrous or textile condition than after they had been carbonized. In the case of the textile materials this arch form would of course be given by simple bending and even in the case of woods, having in view the direction that fibrous vegetable material was to be employed, the workman would realize that he ought to preserve and not destroy the fibrous character of the material while reducing it to the arch form, and would therefore give it this shape by bending, and certainly not by so cutting it as to run across the grain and thereby practically destroy or render useless the fibrous structure of the material employed. In addition to these directions the patent also tells the artizan that this arched conductor may be made of paper, and under this instruction it seems to me that if the said artizan were possessed of ordinary intelligence he would, as a matter of course, shape his paper material before carbonizing it, and would select a variety of paper consisting of pure vegetable fibre unadulterated with mineral matter. Many such varieties of paper were known in the arts and easily procured. It is hardly necessary to say that an intelligent artizan would also select a paper of uniform thickness and fine structure and not a coarse and irregular specimen, which he would know must produce an irregular, and therefore inefficient, conductor for an incandescent electric lamp. It would also be true that if the supposed artizan was familiar with the art of electric lighting, as it existed in 1880, he would know about the methods of tempering or treating carbon conductors set forth in certain earlier patents of Sawyer and Man, and would therefore be prepared to subject his carbon conductor to such treatment if he found it desirable or necessary.

As to carbonization of the material after it had been selected and prepared by shaping, it seems to me that no specific instruction would be needed, because any one skilled in the art would be quite familiar with such methods of carbonization as would be 1979 manifestly efficient for the object in view. In other words, he would not need to be instructed that to carbonize relatively small and delicate objects like these, they should be inclosed in air-tight crucibles, being either pressed between surfaces or imbedded in carbon powder or the like, in such a manner as to exclude air as far as possible.

Having thus stated what I myself find in this patent in the way of directions as to the selection of material, its preparation and carbonization, I will take up in order and consider the various statements made by defendant's experts as to this same subject.

In considering the opinions expressed by defendant's experts, I should, in the first place, make the general remark that all these gentlemen seem to have overlooked the true significance of the expression "textile material" and to have directed their attention almost exclusively to the term "wood carbon." They have also, as it seems to me, assumed that the artisan attempting to follow the directions of this patent would fail to consider at once all its instructions and suggestions and would refer to only one at a time and would then proceed to consider that one with little or no reference to the state of the art and to the indications which the existing state of the art would furnish him as guides in his selection of material and treatment thereof. They also seem to assume that in order to be practically useful, an incandescent lamp must be able to compete successfully in cost and convenience with illuminating gas and even to rival the improved incandescent electric lamps of the present day, and they also, as I think, assume that to be practicable and useful, even in 1880, an electric lamp must have a carbon conductor of higher resistance, and of more slender structure than many which are in successful commercial use, even at the present day. These partial, or piecemeal methods of considering the patent, and these
various assumptions are, I think, quite unphilosophical and
1980 unwarranted, and when they are corrected, all grounds for
the opinions as to the insufficiency of the instructions contained in this patent, disappear.

Thus, for example, taking up first Dr. Barker's testimony as expressed in his answer to question 22, his first objection is, that the expression "a vegetable, fibrous material in contradistinction to a similar conductor made from mineral or gas carbon," and the expression "vegetable, fibrous or textile material," would cover thousands of distinct forms of vegetable materials, among which the artizan would be at a loss how to select, because unprovided with any criterion by which to discriminate. This, however, could only be so if the artizan in question failed to realize the force of the suggestion contained in the term "textile material," and also failed to realize the force of the term "fibrous," as meaning distinctively and characteristically fibrous, to a marked and practically effective degree, and finally also failed to realize that the state of the art instructed him that the carbon conductor must be of uniform structure and conducting power throughout its length. He must also fail to realize that according to the direction of this patent the finished conductor was to have an arched form.

If, on the other hand, the intelligent artisan realized all these things, then he would not see before him the thousands of vegetable structures among which Dr. Barker thinks he would be lost, but, as I have already pointed out, would have clearly indicated to him, in the first instance, such textile materials as cotton and linen thread; in the next place, such less familiar textile materials as the split canes, bamboos and the like as were also used for textile purposes; and lastly and only as a more remote suggestion, the use of such woods as by their peculiar, regular and even, fibrous structure were allied to the textile materials which would naturally be his first choice.

Dr. Barker next refers to the mention of paper as a material for the production of the carbon conductors, and thinks that because there are many varieties of paper, some of which by reason of 1981 the mineral impurities which they contain or their coarse and irregular structure would be unfit for the use indicated, the supposed artisan would be at a loss which to select and could only determine this by repeated experiment. This, however, I think, does great injustice to the intelligence and knowledge of the supposed artisan, who I think would undoubtedly know that in order to produce an article from paper which was otherwise to be made from vegetable fibre, he must select a pure paper not contaminated or loaded with mineral matter, and that to produce a carbon conductor of uniform resistance or conductivity, he must use a paper of fine and uniform structure and thickness, such, for example, as the familiar bristol-board. If the artisan had selected such a paper he would undoubtedly have succeeded in producing a carbon conductor capable of operating with entire success in an incandescent electric lamp, especially if he had also applied his knowledge and judgment to the extent of treating or tempering said conductor in the well-known manner after it had been carbonized. Among other reasons for this last conclusion I may state that during my experiments on incandescent lamps for the light-house board I operated many lamps whose carbon conductors were made from paper and that these lamps operated in a very satisfactory manner both as regards durability and efficiency.

Dr. Barker next takes up the expression "wood carbon," as though it stood alone and were to be considered without any limitation derived from other parts of the patent. The words as they stand in the patent are in this connection.

"In the practice of our invention we have made use of carbonized paper and also wood carbon."

Now, as I have already pointed out, any artisan of the most moderate degree of intelligence, if directed to make arch-shaped carbons from paper, would unquestionably cut or bend the paper into the arch shape before carbonizing it, and if he found directions or a suggestion as in the above quotation which coupled the making of 1982 carbons from wood with the making of carbons from paper, there cannot be the least doubt that he would also proceed to shape the carbon arches from the wood before carbonizing it. Moreover, if he had studied the rest of the patent and had realized the force of what is there said about textile material and vegetable fibre, and moreover knew something as to the necessity of uniform structure in the conductors of electric lamps, he would not feel that the entire class of exogenous woods was presented to him for selection, but that his choice must be confined to those which by their uniform and fibrous structure adapted themselves for this use and were in fact as closely as possible allied in these characteristics to the textile and fibrous vegetable structures which were manifestly the preferred and specially indicated materials. Had he used such knowledge and judgment as I have above indicated, and had he also, for further security, applied the process of tempering or treatment, I have no doubt that he would have produced directly and without experiment an incandescent conductor for an electric lamp which, at the date of the patent, would have been entirely operative and indeed commercially valuable in certain locations, although it probably would not have competed in economy with illuminating gas or with the improved incandescent lamps of the present day.

Near the conclusion of this answer 22 Dr. Barker uses these words:

"The bare statement of the patent in suit, therefore, that the material to be used for the production of the carbon conductor (which is the essential feature of an incandescent lamp), is vegetable fibrous material, seems to me to be utterly vague, indefinite and unsatisfactory, and does not seem to me to be such a full and complete description as would enable a person skilled in the art as it existed at the time the said patent was applied for, to produce a practically operative incandescent conductor without experiment."

1983 Now, if the assumption here made by Dr. Barker was correct, if the patent only contained the bare statement which he makes, then his conclusion might be warranted; but in order to secure this premise, Dr. Barker is obliged to ignore all that the patent says about textile material and the arch shape of the conductor and all that is implied in these and other parts of the document. When these matters are taken into consideration, then the statement of the patent is no longer in the crude and bare condition, to which Dr. Barker would reduce it, but is fully clad with abundant instruction such as would enable one skilled in the art, without experiment, to produce not only one, but several varieties of operative incandescent conductors for electric lamps.

In Dr. Barker's answer to question 23, he points out very correctly that there are many kinds of paper and also of wood, which would not answer for the construction of an incandescent electric lamp, and to his remarks on this subject I will only add that this would be equally manifest to an intelligent artisan who might be called upon to put in practice the invention of the patent in suit, and that such artisan would discard such varieties of wood and paper just as Dr. Barker has done, without experiment.

In his answer to question 24 Dr. Barker says in substance, that he considers explicit directions would be necessary as to the shaping and carbonizing of the conductors, and that said directions are confessedly not given in the patent, but are there stated to be unnecessary. I think that Dr. Barker's error in this as in other cases, arises from his having overlooked or failed to appreciate what the patent says about textile materials. Had he taken this into consideration he must, I think, have seen that the shaping of the material or the selection of the same ready prepared in the desired shape, was a matter not only suggested, but made in many cases absolutely unavoidable, and that this having been done, it was

manifestly unnecessary to instruct any one familiar with the art as to methods of carbonizing, since these were thoroughly well known and clearly defined as to such materials and products as are
1984 involved in this case. It would indeed seem almost an absurdity to tell a workman who had been instructed to make a carbon in an arched form out of a thread of some sort that he was to bend the thread into an arched form and then clamp it between smooth surfaces of resisting material or surround it with carbon powder, enclosed in an air-tight crucible and heat it in a furnace, because it would require more ingenuity than most people possess to devise any other possible way of doing the thing directed in the first case.

In his answer to question 25, Dr. Barker says in substance that it would make all the difference in the world as to the efficiency of the conductor made from wood, whether it was cut with the grain or across the grain, and that the patent contains no specific instructions in this regard and is therefore defective. I agree with Dr. Barker entirely as regards his facts, but not as to his conclusion. Any artisan acquainted with this art would know precisely what Dr. Barker does on this subject, and therefore would need no directions. In fact, to tell him not to cut his conductor across the grain would be as much of a reflection upon his intelligence as to tell him not to make notches in it or to make it of unequal section in different parts.

Dr. Barker's answer to the 26th question is substantially an amplification of what he says in the previous answer, and only expresses what any intelligent workman would know as to the proper or improper means of shaping a piece of wood which was intended, after carbonization, to be used as the incandescent conductor of an electric lamp.

In his answer to the 27th question, Dr. Barker states that an arched carbon made out of wood cut across the grain would not be useful as a conductor for an incandescent lamp, and in this I agree with him, as I think would any intelligent artisan familiar with the art of electric lighting as it existed in 1880.

Turning next to the testimony of Prof. Brackett. In his
1985 answer to question 16 he says, in the first place, that the instructions of the patent are insufficient as regards the selection of material. This opinion he apparently forms on the statement in the patent that the patentees have used carbonized paper, and also wood carbon, taking this statement alone, and making no use of anything else in the patent to qualify or explain it. Like Dr. Barker, he assumes that the artisan who is attempting to follow the directions of this patent would take this sentence by itself and would be ignorant as to the rest of the patent and the state of the art; that he would consequently select indifferently any kind of paper, no matter how impure and loaded with mineral matter, and no matter how rough and irregular in structure it might be; that similarly he would, as it were, go into the forest or to the wood pile and take the first stick he picked up and proceed to use it. After what I have said as to the actual instructions contained in the pat-

ent, and as to this method of piecemeal discussion, it is not necessary that I should here say more than that such an artisan as Prof. Brackett's remarks here imply, is not the artisan of ordinary intelligence, skilled in the state of the art, to whom the patent is addressed, but must be one either lacking intelligence and knowledge or not making use of the same in his attempt to put in operation the invention of the patent.

In his answer to question 17, Prof. Brackett goes over the same ground as Dr. Barker in reference to the necessity *or* cutting the carbon from wood with the grain and not across it, and I would only remark that I quite agree with him, but feel confident that any intelligent artisan would see this thing just as Prof. Brackett and I do, without any experiment being necessary to satisfy either him or us as to the result.

In his answer to question 18, Prof. Brackett points out, in substance, that only a small fraction of the entire number of vegetable growths would be adapted to the manufacture of efficient carbon conductors for incandescent lamps. In this statement, I have no doubt that he is substantially correct, but I do not understand that he has arrived at this conclusion only at the end of an immense 1986 series of experiments in which all these materials have been tested, but that he reaches this conclusion as a matter of deduction from his general knowledge concerning the conspicuous character-stics of the vegetable world and the requirements of a carbon conductor for an electric lamp. This, I think, any intelligent artisan, with the full text of this patent before him, would do equally well, and would be saved from any unnecessary and unsuccessful experiments by those considerations fully stated in the early part of my present answer, which would lead him to select only those few vegetable fibres which would produce efficient conductors, and not any of the numerous class which would be manifestly unfit.

In his answer to question 19 Prof. Brackett states in substance that he does not think there existed in the state of the art in January, 1880, anything which would supply the deficiencies he finds in the patent. With this I so far agree that if these deficiencies existed, or in other words, if we took a single phrase in the patent and considered it alone, we could not supply the imperfect inst-uctions secured in this way by going to the state of the art, since it was precisely the invention set forth by this patent as a whole which added to the existing state of the art the instructions which Prof. Brackett finds lacking in his selected fragments.

In answers 55 and 56 Prof. Brackett says in effect that the terms "fibrous" and "textile" cover in his opinion a great variety of substances and therefore are indefinite. This would be true if these words stood alone, but standing as they do in this patent in connection with the production of arch-shaped conductors for incandescent lamps they are, as I think I have already sufficiently shown, exceedingly clear and precise, and would lead any one who really desired to carry the invention into practice, directly to those materials which experience has shown are of all others best fitted for the construction of incandescent lamps.

In his answer to question 57 Prof. Brackett thinks that the carbonizing process ought to have been explicitly described; that is to say, as to whether, in the case of wood, the conductor was
1987 to be bent into an arched form before carbonizing or cut into such a form, the cutting involving, in the end, a carbon in which the grain would be in part crosswise. As I have already pointed out, it seems to me that directions on this subject would be entirely superfluous and that any intelligent artizan would adopt the expedient of bending the wooden blank before carbonizing, as a matter of course.

In reference to the testimony of Mr. Edison and Prof. Wilson I think I can avoid unnecessary repetition by saying that I find in them nothing substantially different from what I have commented upon in the testimony of Dr. Barker and Prof. Brackett, except that they seem to make more emphatically the assumption that for a practicable incandescent lamp an extremely fine or thin fibre is absolutely essential, and that the patent in suit requires that such fibre should be made out of wood. As regards this I should say that modern practice in electric lighting completely demonstrates that a very fine fibre is by no means universally necessary or desirable. In fact the Edison Company, in what they call their Municipal system, use lamps with carbons very many times as thick as those to which Mr. Edison specially refers in his testimony, and which are the kind commonly employed by his company in household illumination. I might also refer to Complainant's Exhibit Thompson-Houston Lamp, and Complainant's Exhibit Bernstein Lamp, as showing incandescent electric lamps which are used commercially to a considerable extent, and which have carbon conductors even thicker than those of the Edison municipal lamp. Still further, the lamps used in the Heissler system have carbon conductors still thicker than any of these. In all these cases the lamps are used in successive series; that is, are so connected that the current passes from one lamp to the other in succession. It is manifest, therefore, that a very fine fibre is no essential condition for an operative or even a commercial incandescent lamp. It is also manifest that the patent in suit is very far from suggesting that the only or usual material for the production of the carbon con-
1988 ductors is to be wood. On the contrary, as I have already pointed out, the first or most natural selection of an artizan, under the instructions of the patent, would be a thread or string, and if this was employed it is manifest that Mr. Edison certainly could not raise any question as to its operativeness and Prof. Wilson has not raised any which would have any force, if we assume the carbonization to have been effected in accordance with the well-known state of the art and the exercise of reasonable intelligence.

In such cases as make it desirable to use thick carbons, wood, under the conditions which I have previously pointed out, could undoubtedly be employed with success, and the difficulties of section would be undoubtedly less than in cases where a fine or elicate carbon was required, just as in every department it is easier o make a large or coarse thing than a delicate or fine one, but in each case fairness requires that similar and not dissimilar things should be compared and that we should not bring into comparison the material of the most delicate modern lamps with the roughest and coarsest of those suggested in the patent.

In view of this I think it will be very evident that the insufficiency pointed out by Mr. Edison and Prof. Wilson as well as defendant's other experts, does not exist in the patent in suit, but only in the minds of those gentlemen, and result from their erroneous assumptions in various directions which I have pointed out and from their partial or piecemeal discussion of the patent, whereby they have failed to appreciate the true meaning of its various statements, which can only be properly understood, as is the case with almost every documeut, by being considered in their mutual relations and as explanatory one of the other.

Adjourned till Thursday the 11th inst., at 2½ p. m.

1989 NEW YORK, *April 11th*, 1889.

Met pursuant to adjournment.

Present: Counsel as before, and the examination of Prof. MORTON was continued as follows:

7 Q. Do you understand that the patent in suit is limited to any proportions of the carbon either with respect to its length or with respect to its cross-section?

A. I do not.

8 Q. What would determine the size of the carbon, in the mind of a person skilled in the art desiring to practice the invention?

A. The conditions under which the lamps were to be used. If, for example, these lamps were to be used in what is known as parallel series or multiple arc, that is to say, when two parallel main wires are carried out from the dynamo or other source of electricity and the lamps are inserted between them like the rungs of a ladder, then the carbon conductors would be made thin and long so as to secure in them a high resistance. If, on the other hand, the lamps were to be run in successive series, that is, one lamp after another being inserted in the line of the main conductors, then carbon conductors, short and of thick cross-section would be employed so that each lamp would only add a relatively small resistance compared to the entire circuit.

9 Q. In your answer to question 6, you say that defendant's experts assume that for a practicable incandescent lamp an extremely fine or thin fibre is absolutely essential, and that for thicker carbons the difficulties of selection would undoubtedly be less. Please explain more particularly what you mean by this. I call your attention to the testimony of Prof. Wilson contained in his answers to questions 10 to 28 inclusive, in which he deals particularly with the difficulties met with in making very fine filaments out of ordinary exogenous and endogenous woods.

A. Prof. Wilson's very extended discussions of this subject may, I think, be fairly summarized as follows:

1990 All ordinary woods and most endogenous or grass-like plants consist of fibrous structures more or less irregular in character and in direction of their fibres, so that it is in his view practically impossible to cut from any of them a fine filament or thread-like strip which shall be free from very great irregularities or inequalities of structure in its length, owing to the fact that the vegetable fibres in all such materials are bent, distorted or interrupted by the presence of what are called medullary rays' in the exogenous woods and other variations in structure found in them as well as in the endogenous plants. It is manifest to any one that the importance of these irregularities in this, as in any other case, would be lessened just in proportion as the thickness of the conductor was increased, thereby averaging or equalizing the distribution of such irregularities. For example, in a very fine fibre or strip, a medullary ray might entirely interrupt the continuity of the fibrous tissue, but if the strip were ten times as large, then this same medullary ray, if it came near the surface, might only interrupt about one-tenth part of the fibres. So, in another case, the oblique or twisted character of the fibres in a fine strip might cause an absolute interruption of some of them whereby there would be a total interruption of the continuous fibrous structure of the entire strip. If, however, the strip were larger, there might not only be fewer of these fibres interrupted from their running out beyond the limits of the strip, but, even if this were not so, while some fibres were interrupted, others would remain intact, and thus maintain a relative uniformity of continuous fibre throughout the strip. In fact, the whole matter reduces itself to a question of averaging, by which substantial uniformity may be obtained out of great individual variety provided the number of individuals included is sufficiently great.

10 Q. If a person skilled in the art as it stood prior to 1880, had desired to succeed in making very fine or slender filaments by following the directions of complainant's patent, what sort of 1991 fibrous or textile materials would have, in your opinion, suggested themselves to him as most suitable for the purpose?

A. Cotton and linen thread would, I think, have been the first materials he would turn to. After those, such long-fibred grasses, reeds and strips of bamboo as were familiar to every one in the weaving of baskets and similar articles, and then such materials as broom-corn, or those woods like the ash which are noted for their conspicuously straight fibre.

11 Q. Would he naturally have selected woods with interlaced and irregular fibres, or those having very open and porous structure, with the imperfections of which Prof. Wilson's deposition deals at so much length?

A. If his desire was to succeed, I think he would naturally have avoided just such materials as you mention, and it would have been very strange and unnatural for him to have selected them.

12 Q. If carbons very much thicker than the filaments to which rof. Wilson refers were to be made, would the defects to which he refers be fatal or very serious ones, so far as most of the woods are concerned?

A. Not necessarily, and especially not if the process of tempering and treating set forth in the earlier patent of Sawyer and Man was availed of.

13 Q. To what process do you refer, and how would this serve to remedy the defects mentioned by Prof. Wilson and defendant's other experts?

A. The process to which I allude is that which is set forth in two modifications in the patents to Sawyer and Man, one of which is No. 210,809, Dec. 10, 1878, and the other No. 211,262, Jan. 7, 1879. In the first of these, the process is described in the following words, having reference to the gases that may be occluded by the materials enclosed within the lamp:

"To drive these out, we pass an electric current through the conductors *x*, *x*. The carbon pencil N is intensely heated, and considerable heat having extended throughout all the enclosed 1992 material, thus driving out occluded gases, the operation of exhaustion and refilling with nitrogen is continued until finally all the elements of danger are eliminated from the lamp."

The other process, or modification of the process is referred to, in substance, in the following words of the last-named patent:

"We have found that a pencil of carbon immersed in a hydrocarbon liquid and heated to an extremely high temperature by the voltaic current is not itself attacked, but decomposes the surrounding matter, the carbon of which enters and fills up its pores to an extent impossible, except with matter in a very attenuated state, and deposits a perfectly homogeneous layer, generally of a light gray color upon the exterior surface. * * *

"In this process it would seem that the carbon is never in contact with the liquid in which it is immersed, but surrounded by a carbonic gas of a very high temperature."

The reason for this treatment is given at the end of the paragraph immediately preceding the above quotation, in these words:

"Carbons of the ordinary sort, when heated by the electric current, exhibit points and lines of unequal brilliancy. Carbons prepared by our process, when so heated, glow with a uniform brilliancy throughout."

The tempering process described in the first of these patents seems to be a sort of fritting or agglomeration accomplished by the combined influence of a very high temperature, which softens without fusing or vaporizing the particles of carbon, and the exhaustion by which their occluded gases are extracted and their molecules thus allowed to come into closer contact. Its effect is to contract and solidify the carbon conductor and thus to render it more 1993 uniform in character and more capable of resisting destructive influences. The treatment described in the second patent, as the words I have quoted clearly show, consist in a local decomposition of the hydrocarbon vapor, by which the conductor is surrounded during this treatment, with the consequent deposit of carbon upon the parts of the conductor adjacent to where the decomposition takes place.

Now if, as originally made, this carbon conductor had a point of partial fracture or imperfect conductivity as compared with the rest, such point would be more highly heated by the current passing through, than the remainder of the conductor, and, therefore, a greater decomposition and deposit of carbon would occur at this point, thereby filling up the gap or curing the defect in an efficient manner. An extended experience has shown that a conductor, having considerable irregularities when first prepared, may be brought to a state of great uniformity and to an excellent condition for use by this treatment.

14 Q. How largely have these two processes of expelling occluded gases and hydrocarbon treatment been used in the commercial manufacture of incandescent lamps since 1880, and what is their importance or practical value in such manufacture?

A. The process of extracting occluded gases has been, I believe, employed universally in the manufacture of all electric lamps, and the hydrocarbon treatment has been applied in the majority of lamps, although I believe it is not universally used. One or both of these treatments I believe to be essential for the success of an incandescent-lamp factory at the present time. In other words, I do not think that a manufacturer who discarded both these treatments, could at all compete with those who used them, and he could only be successful, if he omitted the hydrocarbon treatment, so long as he confined his selection of material to a very narrow range, and at the same time manufactured his lamps on a very large scale.

1994 15 Q. Defendant's experts are apparently of the opinion that the invention described and claimed in the patent in suit is not the same substantial invention which is described and claimed in the original application. I call your attention particularly to Prof. Barker's answers to questions 28 to 43 inclusive, Prof. Brackett's answers 20 to 37 inclusive, and Mr. Edison's answers to questions 402 and 442 to 467 inclusive. Please compare the specification and claims of the patent in suit with the specification and claims of the original application, as shown by Complainant's Exhibit Patent Office Proceedings No. 1, and state whether or not you agree with the opinions expressed by defendant's experts in regard to the materiality or effect of the various amendments to which they refer, and give your reasons for any opinion you may express.

A. I may say that I very emphatically disagree with defendant's experts on the subject referred to, because, after a careful study of the patent in suit and the original application, I feel convinced that the invention here considered is quite as fully disclosed in the original application as in the patent in suit, and that one skilled in the art, desiring to obtain a successful result, would have succeeded with the instructions of the original application before him just as certainly as if he had the patent in suit in his hands. In my answer to question 6, after quoting from the patent in suit the passages which I consider to embody the instructions of that patent as to the choice and treatment of material, I said as follows:

"The prominent features pointed out by the quoted passages are, that the incandescent conductor is to be made of a fibrous vegetable or textile material in the form of an arch or loop and carbonized so as to be converted into such a conducting material as would be useful in an incandescent electric lamp."

And I also said a little further on in the same answer:

1995 "In addition to these directions the patent also tells the artisan that this arched conductor may be made of paper."

If now we refer to the original application, we will find there clearly stated all the points which I have above referred to as characterizing the invention disclosed in the patent in suit, as well as certain others which I have not yet had occasion to refer to, but will mention presently. In the first place, one of the prominent features of the invention disclosed in the patent in suit, is that the incandescent conductor is to be made of a fibrous vegetable or textile material. Now the 4th claim of the original specification reads as follows:

"An incandescing arc made of carbonized fibrous or textile material."

The only difference between this and the statement of the patent in suit is that in the patent in suit the invention seems to be more specifically limited to vegetable fibrous material than is the original application, although it is my opinion that in both cases vegetable fibrous material is all that is intended to be described. If, however, there is any difference, it is a limitation or restriction as to the range of the invention as expressed in the patent in suit. In the next place, the patent in suit describes, as another feature of the invention, the arch form which is to be given to the carbon conductor. In the second claim of the original application I find these words:

"Incandescing arcs of carbon in combination with the circuit of an electric light."

In the 3d claim,

"an incandescing arc of carbonized paper"

is referred to; and, as I have already pointed out, the 4th claim reads:

"An incandescing arc made of carbonized fibrous or textile material."

Also in the specification of the application I find as follows:

1996 "Our improved burner or incandescent arc consists of an arch-shaped or semi-cylindrical piece of carbon A mounted in its clamps or supports in usual well-known ways."

There are also various other references to the arc shape, but those I have quoted are abundant to show that this feature was fully set forth in the original application.

Again, as I have before pointed out, the patent in suit indicates that the arch conductor of the incandescent lamp is to be carbonized. This I find fully set forth likewise in the original application, as, for example, in the 4th claim, which reads—

"An incandescing arc made of carbonized fibrous or textile material."

This clearly instructs one skilled in the art to take fibrous or textile material, and, having bent it into an arched form, to carbonize the same so as to produce the article or object described, namely, an arch of fibrous or textile material carbonized or converted into carbon.

Another feature of the invention set forth in the patent in suit, as I before pointed out, is the production of the arch-shaped carbonized conductor made from paper. This I find clearly set forth in the 3d claim of the original application in the following words:

"The combination substantially as hereinbefore set forth, of the circuit of an electric light, an incandescing arc of carbonized paper included in the circuit, and a close, transparent chamber in which the arc is enclosed."

Also in the specification I find the expression—

"We have tried carbonized paper covered with powdered plumbago."

These references, I think, clearly show that all the features heretofore referred to by me as distinguishing the invention of the patent in suit are fully developed in the original application.

Adjourned till Friday, the 12th inst., at 10½ a. m.

1997 FRIDAY, *April* 12, 1889.

Met pursuant to adjournment. Present, L. E. Curtis and Edmund Wetmore, Esqrs., for complainant, and H. D. Donnelly, Esq., for defendant, and the examination of Dr. MORTON proceeded as follows:

Witness continues his answer 14.

From the character of the questions so far put, I have not had occasion to consider as yet another feature of the invention as expressed either in the patent in suit or in the original application, viz., the inclosure of the incandescent conductor in a transparent hermetically-sealed chamber as the patent in suit expresses it in the second claim, or an illuminating chamber made wholly of glass hermetically sealed and out of which all carbon-consuming gas has been exhausted or driven, as the patent in suit expresses it in its fourth claim. This feature, or these features, in whichever way we may choose to consider them, I find fully set forth in the original application in the following words and references. To begin with, in the statement of invention in the application I find as follows:

"Our invention, speaking generally, relates to that class of electric light employing an incandescent conductor enclosed in a vessel or chamber from which oxygen is excluded, and constitutes an improvement upon the apparatus shown in letters patent, No. 206,144, granted to us June 18, 1878."

(I understand that the number of the patent above given is an error which has been corrected and that the patent actually referred to is No. 205,144, which was in fact granted to Sawyer and Man, June 18, 1878.)

Turning to this patent I find it to describe fully and in detail an incandescent electric lamp having a carbon conductor enclosed in an air-tight vessel made entirely of glass. This last feature is specially set forth in the following words:

"Referring to figures 1 and 3, A is the glass globe provided 1998 with a rim or flange A^1 (better shown in Fig. 6), by means of which it is clamped to the glass base or stopper B, (better shown in Fig. 7)."

Also the following:

"To the base of the globe is ground the glass stopper B (better shown in Fig. 7), with great nicety, in order that the fit may be perfect."

Also the following:

"The rubber flange may however be omitted, and the form of the stopper B may be changed to that of a stopper ground into the end of the globe A, as stoppers are ground into bottles."

"In setting up the lamp we slightly coat the lower ground edge of the rim A^1, with fir balsam or some cement, in order the better to insure that hermetrical sealing which is indispensable to the preservation of the incandescent conductor."

As regards the exclusion of all carbon-consuming gas, the patent 205,144, is so full of references to it that it is hard to select any special part for quotation, but I would refer to the statement of invention on the first page and to the three last claims as bringing this feature out very prominently.

I think, therefore, that the statement of the original application which I have above quoted, taken in connection with the patent to which it refers, very clearly and fully describes a transparent, hermetically-sealed chamber in which the conductor is enclosed, or an illuminating chamber made wholly of glass, hermetically sealed and out of which all carbon-consuming gas has been exhausted or driven.

Turning again to the original application, I find near the end of the specification the following paragraph:

"We have used such burners in close transparent chambers, in a vacuum, in nitrogen gas, and in hydrogen gas, but have attained the best result, in a vacuum or attenuated atmosphere of 1999 nitrogen, the great desideratum being to exclude oxygen from the combustion chamber as is well understood."

These words, as it seems to me, taken in connection with those I have before quoted from the original application including the reference to patent 205,144, very clearly point out, as one department of the invention, the use of a hermetically-sealed chamber, entirely of glass, from which all carbon-consuming gas has been exhausted or driven, and thus contains everything on this subject which is set forth in the patent in suit.

Considering this subject at large then, I think that it is manifest from all the above, that the original application, equally with the patent in suit, contains everything necessary for the successful construction of the apparatus referred to and for reducing to practice the invention set forth in said patent in suit.

Turning now to the opinions expressed on this subject by Dr. Barker in his answers referred to, I would say as follows:

In his answer to question 28, Dr. Barker states in substance that he finds the patent in suit to differ from the original application, because, as he understands it, the invention set forth in the application is limited to, or consists of, a peculiar form or shape for the carbon forming the incandescent conductor of the electric lamp, and makes no reference to the material out of which the incandescent conductor is to be formed, except such as is entirely incidental and likewise indefinite, whereas, on the other hand, the patent in suit states that the invention relates to the substance as well as to the form of the incandescing conductor. Now, in this opinion, I think that Dr. Barker is entirely in error, and for a very manifest reason, mainly because he has entirely overlooked the significance of the fourth claim of the application, which is

"an incandescing arc made of carbonized fibrous or textile material."

2000 That he has overlooked this claim, appears very clearly from the following words which occur at about the middle of his answer to question 28.

"This conclusion that the invention of the application consists in the use of incandescing arcs of carbon, and that the material is specifically unimportant, would seem to be confirmed by the fact that the first two claims refer only to carbon arcs in general."

It is, however, manifest that whatever support is given to the view that the material is unimportant, because not mentioned in the first two claims, is entirely removed when we find that the material is made the special and emphatic subject of the fourth claim. Indeed, if there was no other reference in the entire patent to the material except what is contained in this fourth claim, it would still be, it seems to me, very clear that the material to be used was shown by this statement as an important and essential feature of the invention, but, besides this, we have in the third claim an equally prominent and emphatic reference to carbonized paper, and we have also in the specification the words:

"We have tried carbonized paper covered with powdered plumbago, wood carbon or charcoal, and ordinary gas carbon."

Now to my mind this statement, taken in connection with the fact that paper and fibrous textile material are the only substances alluded to in the claims, makes it very clear that the inventors intended to indicate, and have clearly indicated, that these are the substances which they specially valued and desired to cover by their application, and I do not find anything in the patent which is more clear and emphatic than these statements in the application as to the selection of material, or more certain to lead one skilled in the art directly and necessarily to the choice of such material as would have produced the operative and useful result to be sought for.

2001 In the next place, Dr. Barker says in substance that he thinks the materials specified to be used, have been greatly expanded in the patent as issued, as compared with the application, because, in the first place, the application speaks of carbonized paper covered with powdered plumbago, while the patent in suit speaks of carbonized paper without referring to the plumbago, and that where wood carbon or charcoal occurs in the application, wood carbon only is mentioned in the patent in suit, and, lastly, because the words "ordinary gas carbon" are omitted from the patent in suit and the substance to be used for the incandescent conductor is stated to be carbon from vegetable fibrous material in contradistinction to a similar conductor from mineral or gas carbon.

As regards the first of these distinctions, *i. e.*, the omission of powdered plumbago, I should say that I consider this entirely immaterial. In other words, carbonized paper covered with powdered plumbago was substantially carbonized paper. In the manufacture of the ordinary carbon pencils used for electric lights it was usual to finish them by rubbing them over with powdered plumbago, which gave them a relatively glossy surface, improving their appearance but having no substantial effect upon their electrical properties. This I understand to be the treatment referred to in the application where it speaks of carbonized paper covered with powdered plumbago, and the product thus indicated would be substantially a conductor of carbonized paper and nothing more, just as a stove treated with stove polish (which, by the way, is substantially powdered plumbago) would be neither more nor less a stove after such treatment. It was, therefore, I think a perfectly proper change, involving no substantial or material modification, to omit this reference to plumbago and to speak of the carbonized paper in the patent without this addition, just as it was referred to in the third claim of the application, where it is described as an arc of carbonized paper.

As regards the second point, the omission of the word "charcoal," this appears likewise to be a very proper change and 2002 to have acted in fact as a means of narrowing and not expanding, the subject-matter. "Charcoal," in the art of electric lighting, was undoubtedly used very generally as an expression for any kind of carbon electrode used for producing the ordinary electric light. The way this came about was very natural. The electric light when first exhibited by Sir Humphrey Davy was made between electrodes of wood charcoal, and though it *it* was very soon found that the hard carbon obtained from gas retorts and known as gas carbon was, in many respects, much better for this purpose, and was consequently generally substituted for wood charcoal, the old name was still employed for the new substance, and, even when the artificial carbon rods made by various methods came to be employed in electric lamps or regulators, the name "charcoal" was still very frequently used to designate them. This appears from a number of references to patents stated in the deposition of Prof. Cross in this case in answer to question 5, and also from the following references which I will quote:

"A Manual of Electricity, etc., etc., by Henry M. Noad, Ph. D., F. R. Soc., London, 1859, p. 316.

"It is this more rapid consumption of the positive than the negative carbon which has hitherto been one of the chief difficulties in the application of the electric light to practical illumination. Many attempts have been made to overcome this difficulty, but the most ample, perfect and portable apparatus are those invented by M. Jules Duboscq and by M. Deleuil.

"The object to be attained is the maintenance of the charcoal terminals at a constant distance from each other. The lower or positive carbon is, in Duboscq's lamp, pressed upward by a spring, the action of which is regulated by an endless screw set in motion by a lever which is worked by an electro-magnet; this electro-magnet, inclosed in the pillar of the lamp, is only active when the circuit is complete; the moment therefore the *charcoal* terminals become separated, its iron keeper is detached, and the action of the spring, previously restrained by the screw, is put in force
2003 and the carbon terminals are again brought into contract.

"P. 317, Fig. 179, represents the arrangement of Foucault's experiment of throwing the image of the carbon terminals during ignition, by means of a lens, on a screen, and shows in a beautiful manner, the gradual wearing away of the positive, and the increase of the negative carbons. The small globules or specks observed on the *charcoal* arise from the fusion of the minute particles of silica contained in the *coal*. When the voltaic current is thrown on, the negative carbon first becomes luminous. * *

"P. 315 (413) Fig. 175, represents the appearance presented by the voltaic flame between pencils of 'well-burned boxwood *charcoal*, or, which answers better, between pencils formed of that plumbago-like substance found lining the interior of long-used gas retorts." (The italics in the above quotation are mine.)

Even in works on chemistry, it was usual to employ the term "charcoal" very broadly, to cover any artificial carbonaceous product, as distinguished from the natural carbon in the form of coal. Thus, in the extended work by Gmelin on chemistry, in nineteen volumes, I find in volume 2, page 86, as follows:

"2. Charcoal. This form of carbon is obtained by strongly igniting in a covered vessel such non-azotized organic compounds, as, on burning, leave no fixed residue, *e. g.*, pure sugar—or by passing the vapors of volatile organic compounds, such as alcohol, ether, volatile or fat oils, through white-hot porcelain tubes. Page 84, Cagniard Delatours artificial diamond is charcoal intimately mixed with a hard crystalline slag containing aluminia and sesqui oxide of iron, together with silica and sesqui oxide of manganese."

In Knapp's Chemical Technology, vol. 1, p. 59, I find as follows: "Carbonization of pit coal. General principles. The charcoal which is left as the residue after the action of heat upon pit coal is commonly called coke."

Such references might be indefinitely multiplied, and indeed in

French works the word charbon, which strictly means char-
2004 coal, is almost always used for every form of carbon, although the word carbone, which strictly means carbon, is also occasionally met with.

In view of this breadth and indefiniteness of the word "charcoal," it seems to me evident that its omission from the patent in suit was highly proper, and decidedly in the direction of narrowing the scope of the invention.

Lastly, Dr. Barker, at this place refers to the omission of "ordinary gas carbon," as one of the possible materials for the incandescent conductor in the patent in suit. This is undoubtedly a change, but it is a change in the direction of a narrowing or limiting the scope of the invention, and the result of it is, that, while conductors of an arched form made from this kind of carbon would be included under some of the claims of the first application, they would not be included under any claim of the patent in suit.

In his answer to question 29, Dr. Barker says, in effect, that he does not consider the references to carbonized paper in the 3d claim, and to carbonized fibrous or textile material in the fourth claim, such as to indicate a preference for a specific kind of carbon. As to this, I can only say, that I entirely disagree with him, and think, on the contrary, that it would be impossible for a patentee to more emphatically indicate his preference for certain materials, than by making them the prominent features in special claims, as is here done.

In his answer to question 30, Dr. Barker again refers to the omission of the word "charcoal," and suggests an imaginary reason for this change. It does not seem to me that any such exercise of the imagination is called for, or that there is any foundation for the assumptions made by Dr. Barker, viz., that the inventors, between the times of their application and the issue of the patent, found out that charcoal was not a good material and must be excluded. What I have already said as to the undoubted breadth and ambiguity of the word "charcoal," furnishes, I think, an abundantly sufficient reason for the change.

In his answer to questions 31 and 32, Dr. Barker states
2005 in effect, that he agrees with Mr. Pope in thinking the words "wood carbon" and "charcoal" to be used as alternative expressions in the application, and that he also thinks that either term was intended to indicate commercial charcoal, or the result of any process of carbonizing wood. I agree with him as to the first part, but not as to the last of this statement. In other words, I think that the patentees intended in the application to indicate equally by the term "wood carbon" or "charcoal," the carbonized vegetable fibre or textile material specially indicated in their fourth claim, and that they used these words just as one might to-day use them in reference to the ordinary incandescent lamps in general use.

It would be quite correct to-day, in one sense, to speak of the incandescent conductors of ordinary electric lamps as consisting of wood carbon or charcoal, but it would involve undoubtedly some ambiguity, and it was, I think, to rid themselves of this ambiguity that the term "charcoal" was omitted from the patent in suit, as I have already pointed out.

In Dr. Barker's answer to question 33, he expresses his inability to understand what was meant by the expression "carbonized paper covered with powdered plumbago," although at the outset he says:

> "It seems to me that it means paper which has been carbonized and which is covered with plumbago."

This first impression of Dr. Barker's seems to me to have been a very correct one and agrees entirely with my own, and I think if Dr. Barker had remembered in this connection the common practice of finishing off carbon electrodes by rubbing them over with pulverized plumbago, which is, among other places, referred to in the Carré French patent No. 111,064, January 15, 1876, he would have been satisfied with his first impression without the rather unsuccessful efforts to develop it by considering all the possible or 2006 impossible processes that might be adopted to produce a piece of paper which had been carbonized and covered with plumbago.

In his answers to questions 33½, 34, 35 and 36, Dr. Barker in substance considers more in detail what strikes me as an utterly irrational suggestion as to what might possibly be meant by carbonized paper "covered with plumbago," viz, that it meant paper which had been covered with plumbago first and then attempted to be carbonized afterwards, not by any known process of carbonization, but by the passage of an electric current. As this entire suggestion seems to me utterly impracticable and indeed bordering on the limits of absurdity, it is hardly necessary to follow through all that has been said about it, but I will only say that in my opinion no such idea ever entered the minds of the inventors or is expressed in their application, and therefore that no change from an inoperative to an operative method is involved in the statement in the patent in suit where the words "covered with powdered plumbago" are left out and only the words "carbonized paper" are used.

In his answer to question 37, Dr. Barker states in substance that he agrees with Prof. Brackett in the opinions expressed by the latter in answer to questions 25, 26 and 27, and that he thinks the invention described in the patent in suit has been expanded so as to include structures quite different from those contemplated by the inventors at the date of the first application.

Having already pointed out that the original application contains everything necessary for the production of an efficient incandescent electric lamp containing every feature set forth in the patent in suit, I do not think it necessary to further discuss the imaginary motives which Dr. Barker assigns in this answer, as the reasons for equally imaginary and non-existent changes, and therefore I will only say, in this place, that I disagree entirely with the opinion here expressed by Dr. Barker as to the existence of any such changes as he suggests between the application and final patent, 2007 and therefore, of course, as to any significance which he supposes he has found in these changes which he has imagined.

Dr. Barker, in his answer to question 38, goes over substantially the same ground as in his previous answer, that is, assumes that differences exist and points out their significance. I have entirely failed to find any such changes, and therefore, of course, fail to see any such significances.

In his answer to question 39, Dr. Barker simply states his agreement with Prof. Brackett, and I will therefore leave that subject until I take up Prof. Brackett's own statement.

In his answer to question 40, Dr. Barker says in substance that he does not think that the mere mention of carbonized paper in the application, by itself indicates that the inventors intended to employ a fibrous material, shaped before carbonizing, or that a successful result would necessarily follow a process of construction founded upon such a meagre suggestion. Under the peculiar conditions assumed in this question and answer, Dr. Barker might be correct, but these assumptions do not represent anything before us in the present case. As I have already fully explained, the reference to carbonized paper is the least part of the instructions given by the original application on this subject, and I do not think there can be a shadow of doubt in any unbiassed mind that an intelligent artizan, with a knowledge of the art up to 1880, and the original application before him, would be certainly successful in producing an operative incandescent electric lamp by simply following, in the most straightforward and natural way, the directions and indications contained in that document.

Turning next to the testimony of Prof. Brackett, I find that in his answer to question 20, he states in substance that he finds only a remote and distant connection between the invention described and claimed in the patent in suit and the invention described and claimed in the original application. His reasons for this general opinion seem to be that he finds in the original specification special prominence given to the form of the incandescent conductor, while in the patent in suit the material of this conductor is made 2008 equally if not more prominent. As I have already pointed out, however, and as Prof. Brackett cannot, I think, deny, the material is clearly indicated and expressly claimed in the original application, and a change as to the relative prominence of two features, even if it existed, would involve no substantial modification of the invention, both features being in both documents fully stated and distinctly claimed. In the next place, Prof. Brackett remarks upon the omission of the "powdered plumbago" in connection with the "carbonized paper." What I have said in reference to this point in connection with Dr. Barker's remarks on the same subject, will apply to this case and need not be repeated. It is, I think, perfectly clear that the omission of "powdered plumbago" has no substantial effect or significance. Prof. Brackett next mentions the omission of "gas carbon." This, as I have already pointed out, is a change tending to narrow the scope of the invention and therefore altogether proper and commendable.

In his answers to questions 21, 22, 23 and 24, Prof. Brackett goes over the same ground about "wood carbon" and "charcoal," carbonized paper covered with "plumbago," and the possible and impossible processes which might be supposed to result in the production of such an object, which I have already discussed in connection with Dr. Barker's testimony, and I will, therefore, only say in this place that my previous remarks apply to these answers of Prof. Brackett, as they do to the corresponding ones of Prof. Barker, and, therefore, need not be here repeated.

In this connection, however, I will add a quotation from Mr. Edison's testimony showing his opinion as to this remarkable method of interpreting the expression "carbonized paper covered with pulverized plumbago."

"Question 445. In your opinion could a practical carbon for incandescent lamps be made by impregnating paper, such as blotting paper, with powdered plumbago, and then carbonizing it by passing an electric current through it?

2009 A. Do you mean in a vacuum or how?

446 Q. Either in vacuum, or air or nitrogen or illuminating gas?

A. My opinion is that it would require a great stretch of the imagination on the part of any expert skilled in the art, to conceive of a practical filament being made in this way. If you carbonize in vacuum there is never any carbon left in the paper. There is about forty-seven per cent. of carbon in paper, the balance being water and the oxygen of the water is sufficient to burn up all the carbon."

In his answers to questions 25, 26, 27, 28, 29 and 30, Prof. Brackett discusses the question of the enclosing chamber as referred to in the patent in suit and in the original application, and expresses the opinion that there is a radical difference in this regard between the inventions described in these two documents in this respect. In this, however, I entirely disagree with him. He does not seem to have realized that the reference in the application to the prior patent 205,144, practically brings everything contained in that patent into the application, and that, if we study the structure shown and described in that patent, we shall find it to contain everything that is indicated in the patent in suit and to correspond accurately with the language of this final patent.

Prof. Brackett seems to find particular difficulty with the passage in the patent in suit which states — "the sealing of the electrodes where they pass through the glass wall is done with any suitable cement, or in any of the well-known methods of sealing glass upon metal electrodes previous to the filing of this application," which he does not find in the original application. Now, in reference to this, I think it is only necessary to say that the earlier patent, 205,144, having described fully various methods of sealing in the electrodes,
2010 all other methods known at that date were by implication
included, and the use of them would have been involved

without any further statement or specification. Consequently, the specific statement on this subject referred to, is no change or addition to the invention, but is simply explanatory, and therefore is an entirely proper addition to the original application.

In reference to the comments made by Mr. Edison as to the differences he finds between the original application and the patent in suit, I used only say that I find in them nothing differing in substance from what has been already referred to in the depositions of Dr. Barker and Prof. Brackett, and that they, like the comments of these gentlemen, entirely lose weight and relevancy when each document is considered as a whole, and such fair interpretation is given to its various statements as I have endeavored to set forth in the early part of this answer.

Adjourned till Saturday, the 13th inst., at 10½ a. m.

NEW YORK, *April* 13, 1889.

Met pursuant to adjournment. Present: Mr. Wetmore for complainant, and Mr. Donnelly for defendant.

16 Q. Do you find anything described and referred to in any of the claims of the patent as issued which you do not find described in the application as originally filed?

A. I do not.

17 Q. Do you agree with the opinion expressed by defendant's experts that there is no suggestion in the application as originally filed that would lead a person skilled in the art to shape the material in either dimensions before carbonization, or to select such material as was already shaped? I call your attention particularly to Prof. Brackett's answer to question 22 and Prof. Barker's answers to questions 41 and 42.

2011 A. I do not at all agree with defendant's experts, but on the contrary consider that the original application contains very clear and distinct instructions, leading, first of all, to the selection of material which would be of necessity already shaped prior to carbonizing, and, secondly, to the shaping of such material as might require it, also prior to carbonizing.

In Prof. Brackett's answer to question 22 he confines his attention, as directed in the question proposed to him, to the words "carbonized paper covered with powdered plumbago." This of course places him at a great disadvantage as compared with an intelligent artizan, who would have had the entire patent before him, and, having been put on the right track by the references to textile material and vegetable fibre, would require the exercise of considerable ingenuity to escape seeing that the paper carbon was to be shaped prior to carbonizing just as the threads and other textile materials made of vegetable fibre had been. But even aside from this, I am at a loss to understand how any one under any circumstances should fail to perceive that when they were directed to make a conductor in an arch shape out of carbonized paper, the proper and natural way of carrying out such instructions, would be to cut the paper into the arch shape, or cut it into a straight strip and then bend it into an arch shape, prior to carbonizing.

Prof. Barker in his answer to questions 41 and 42, cannot claim the same excuse as Prof. Brackett, because, though the questions limited him to the words "carbonized paper covered with plumbago," or rather "carbonized paper," he says at the opening of his answer to question 41,

"I do not find in the application referred to any expression whatever which seems to me to justify such a conclusion,"

which would certainly imply that he had taken into consideration, not only the special reference to carbonized paper, but also the entire application. Such a conclusion, founded upon such premises, is to my mind simply irrational, and I can hardly believe that Dr. Barker really meant what he says in this place. This impression is confirmed by what follows in his answer, in which there is no reference whatever to those parts of the application which so clearly indicate the shaping before carbonization of a fibrous or textile vegetable material, but where I find an extended reference to a series of imaginary difficulties which would never present themselves to an intelligent artizan or require any experiment to overcome them, except such trials as to the best dimensions and proportions as are usual in the construction of any new form of machinery or apparatus. 2012

Dr. Barker's suggestion in his answer to question 42, that the "carbonized paper covered with plumbago," might mean paper which was covered with powdered plumbago and then carbonized by an electric current (which even Mr. Edison considers absurd), and that it might mean carbonized paper covered with so much powdered plumbago that the carbonized paper would be of no account, and the pulverized plumbago be the efficient conductor (this being in a patent in which the fibrous character of the material is so clearly developed as in this), do not seem to me to be worth serious consideration, and their force or weight becomes emphatically a vanishing quantity if we consider what the application says elsewhere, as well as what it says in the few words specially referred to.

18 Q. What is your opinion as to whether or not it would naturally occur to any electrician that he could change the thickness of the paper after carbonization, as suggested by Prof. Brackett and Prof. Barker?

A. I think that any electrician who had any familiarity with the property of carbonized materials would know that, while it might be a possible thing by the use of great skill and the expenditure of much time, to change the dimensions or shape of a piece of carbonized paper after carbonization, such a thing would be a mechanical feat of the greatest difficulty, and would be all but infinitely more difficult than to shape the paper beforehand and carbonize it afterwards. Moreover, he would know that his chance of producing a conductor of uniform conductivity would be almost infinitely greater when he shaped the paper before carbonizing than when he shaped the carbon afterwards. 2013

19 Q. Have you read the testimony of Profs. Brackett and Barker herein, and examined all the patents and publications put in evidence by the defendant relating to the prior state of the art?

A. I have.

20 Q. Defendant's experts have expressed the opinion that in view of the prior state of the art as shown in said patents and publications, there was "no novelty in the use of vegetable fibrous carbon as the incandescent conductor of the lamp of the patent in suit." Please state if you concur in this opinion, and give your reasons for any opinion you may express. I call your attention particularly to Prof. Brackett's answers to direct question 5, and cross-questions 41, 42 and 43, and Prof. Barker's answers to direct questions 9 and 47, and cross-questions 56 to 65 inclusive?

A. In his answer to question 5, Prof. Brackett enumerates and describes a long list of patents and publications which he there seems to think in some way or other anticipate the invention set forth in the patent in suit, but in his answers to questions 41, 42 and 43, he narrows down this broad field, by admitting that the best references as regards the use of a fibrous carbon or carbon made from a fibrous substance, are to be found in a paper by Violette, the description of Sidot's process, and the Binks English patent; and as anticipating the combination of the second claim of the patent in suit, that is, the combination of an incandescent conductor of carbonized fibrous materials with a transparent, hermetically sealed chamber, he finds the best anticipations in the English patent to De Moleyns, that to Greener and Staite, that to Shepard, that to Roberts, and the Lodyguine publication.

Dr. Barker, in his answers 9 and 47, in effect agrees with Prof. Brackett as to his large number of anticipations, but in his answers 51 to 65 inclusive, he also limits this broad field to the following publications, viz., English patents to Roberts, Shepard, Greener and Staite, and Konn, and the Lodyguine publication. Combining
2014 these together, we have the English patents to Roberts, Shepard, Greener and Staite and the Lodyguine publication agreed to by Profs. Barker and Brackett as the best anticipations, and the patents of Binks, Konn and De Moleyns, and the papers of Violette and Sidot referred to by one or the other of these gentlemen.

These I will consider in the order in which I have just named them.

In the first place, Roberts' English patent No. 14198 of 1852. On page 11 of this patent there begins a description of an incandescent electric lamp consisting of "a thin piece of graphite, coke or charcoal or other infusible body being a conductor of electricity while it is enclosed in a vacuum or space not containing any oxygen or other matter which can cause the combustion or destruction of it when brought into an incandescent state by the action of the current of electricity." There then follows the description of the lamp, having reference to a drawing. In this description the incandescent conductor is referred to six times as "graphite," and never by any other name. It is also shown in the drawing as a straight rod held between two clamps. It would therefore appear that in this patent there is no reference whatever to a conductor of an arched form, none whatever, nor the remotest suggestion, as to the employment of a fibrous or textile material which might be shaped prior to carbonizing, and no reference, even the most remote, to anything having a fibrous structure, except the one use of the word charcoal, provided we understand that word in its popular sense as meaning wood charcoal and not in its electrical sense as meaning such forms of carbon as were generally employed in electric lamps. In my opinion it is perfectly manifest that the word "charcoal," as used in this patent, is used in its technical electric sense, and does not mean wood charcoal, but does mean any of the various artificial carbon structures such as were used, and are used, in the production of the ordinary electric light, viz., the arc light. The repeated use of the name 2015 "graphite," and the knowledge which existed at that date that graphite possessed superior forms of resistance to any other form of carbon except the diamond, would, I think, of necessity result in the conclusion on the part of any one reading this patent that graphite or graphite-like material, such as gas-coke or similar resisting carbon, was the material to be used in carrying out this invention, and that to use wood charcoal or any like vegetable product would be to depart radically, and probably with disastrous results, from the instructions here given.

It is also to be noticed that in the description of the Roberts lamp, there is no instruction nor suggestion as to the making the transparent lamp chamber entirely of glass, but, on the contrary, the structure is shown as a flask-shaped globe cemented into a metallic cap, through which the electric conductors are passed, one of them, at least, being surrounded by an insulating sleeve of ivory. From this, I think it will be very manifest that not one of the important and characteristic features, which I have especially pointed out as distinguishing the invention of the patent in suit, is found in this Roberts patent. That is, it neither shows an arch-shaped incandescent conductor, nor one made from vegetable fibrous or textile material, nor an enclosing air-tight chamber made wholly of glass, and, therefore, in no respects at all, anticipates the invention of the patent in suit.

Considering next the Shepard patent No. 13302, of 1850, I find this to describe at page 9, an apparatus which may be correctly described as one for producing light by what is known as the arc incandescent system, that is, a system in which light is produced by the passage of an electric current through the high resistance produced by the imperfect contact between two pieces of carbon, one of which is continually fed forward as it is consumed at the end where the imperfect contact exists. In the apparatus described in this patent, there is a small cylinder of charcoal supported and guided by a vertical metal tube, within which it slides. The lower 2016 end of this rod of charcoal rests on the upper end or apex of a cone of "prepared charcoal or coke." Both of these are supported within a glass globe having a carefully luted stopper, and proper electrical connections. The only available light produced in this apparatus, would be that developed at, and close to, the point of contact between the conical point of prepared charcoal or coke, and the end of the cylindrical rod of charcoal, because the rest of the charcoal would be enclosed within the copper tube. Even then, if we assumed that in this case this thin rod of charcoal was made of wood charcoal, which perhaps it may be in view of the distinction that the little cone D is of "prepared charcoal or coke," the thin rod of charcoal would not act as the incandescent conductor of an electric lamp, because, in the first place, even if it acted by incandescence, the light so produced would not be availed of in the lamp, and, secondly, because it would not act properly by incandescence, but could only operate by the arc incandescent action which I have before stated. In addition to this, it is manifest that there is no suggestion of an arched form, nor of the use of vegetable fibrous or textile material in any way in which the peculiar properties of such substances would come into play. I should therefore say that, in the first place, this was not an incandescent lamp in the proper sense of that word at all; that it had no incandescent conductor in the proper sense of that expression as constituting part of an electric lamp, and nothing which would either suggest or admit of making such a conductor in an arched form, and likewise no suggestion of the use of fibrous or textile material in the production of any part of the lamp. It is, therefore, plainly no anticipation of the patent in suit.

Considering next the patent of Greener and Staite, No. 11076 of 1846, I do not find that this describes any form of apparatus, but in the first place, simply states in general terms that the inventors propose to illuminate various places by means of solid prisms or cylinders of carbon enclosed in air-tight vessels of glass or some other transparent substance, and ignited, or rendered luminous, 2017 by currents of voltaic or magnetic electricity, such carbon being previously freed from the impurities with which it is ordinarily combined, etc. The patentees then proceed to describe at length their method of producing the carbon material, in which they start with lamp-black or charcoal or coke, all reduced to powder. These powders they then treat with acids, alkalies and water, and, having dried them, form from them solid prisms or cylinders by means of hydraulic or other presses. They then proceed to describe the uses of these prisms or cylinders in a manner which is only consistent with the supposition that they are employed for arc lights, and then describe a further use which is only reconcilable with the idea that they intended to employ their artificial carbon cylinders in the manner of the arc incandescent lights. Taking it altogether, this patent clearly describes no structure whatever which can be regarded as constituting an electric lamp, but it does describe the manufacture of prisms or cylinders out of various forms of carbon reduced to powder. It says absolutely nothing about forming conductors in an arch shape, and is equally silent as to the use of any fibrous or textile material in the production of carbon conductors, because I do not regard the reference to powdered charcoal as containing the faintest suggestion containing the utility of a fibrous or textile material in the production of an arch-shaped conductor for an electric lamp. As this patent, then, contains not one of the elements constituting the invention of complainant's patent, I cannot see the slightest ground for referring to it as an anticipation of that patent.

Turning next to the Lodyguine publication in the London Journal of the Society of Arts, August 27, 1873: This, as I understand it, is an abstract or translation from a Russian newspaper which describes in a popular way the exhibition of some electric lamps made at St. Petersburgh by Messrs. S. A. Kosloff & Co. In this description the lamps exhibited are referred to as producing their light by the glowing of a piece of charcoal enclosed in a glass tube from which the air has been exhausted and which had 2018 then been hermetically sealed. In this document it is manifest that the word "charcoal" is used, not in the popular signification of wood charcoal, but in the technical electric sense of hard carbon, such as is, and has been almost from the first, used in the production of the arc light. This appears from the second paragraph of this article which read as follows: "By the old method the electric spark was passed between two points of charcoal, each attached to a copper wire connected with an electro-magnetic machine."

I think I can assert with the utmost confidence that an electric light was never produced between points of wood charcoal by a current from a magneto-electric machine. Long before the magneto-electric machine came into use, the pencils of hard carbon were devised and manufactured, and no one would for a moment think of employing wood charcoal, which was entirely unfit for any continuous maintenance of light with these machines, which were specially adapted for long-continued and uniform operation. It is therefore manifest that the writer of this article, when he spoke of charcoal points for the arc light, meant what we should now call hard-carbon pencils or rods made by the process of Carrè or the like, and that, when he used the same word a little further on to describe the incandescent conductors of the electric lamps used at St. Petersburg, he meant the same thing and would convey that meaning to any one skilled in the art who read this paper. Certain it is that there is here no mention of any arch-shaped conductor and no suggestion that such arch-shaped conductor was made out of fibrous or textile material, or even out of paper, or that any of these materials were to be put into an arch form prior to carbonizing. The only feature in common between this description and the patent in suit, is that in both cases incandescent carbon conductors are enclosed in exhausted air-tight glass vessels, but this is certainly not enough to render this publication in any sense an adequate anticipation of the patent in suit with its three prominent 2019 features of an incandescent conductor made of fibrous or textile material, having an arch shape, and being enclosed in a vessel wholly of glass.

Taking up, in the next place, the Konn patent No. 3809 of 1872: This patent describes an incandescent electric lamp consisting of a glass globe or cylinder containing a conductor, preferably of graph-

ite, in the form either of a straight rod or of a V-shaped piece. The glass globe is stated to be hermetically sealed and filled with nitrogen or other gas that does not support combustion. Graphite is described as the preferred material for the conductor, and graphite conductors are alone referred to in this patent, and therefore it seems to me that this patent contains no suggestion whatever as to the employment of a fibrous or textile material for the production of an incandescent carbon, since such material would be the very furthest possible removed from anything that the name graphite suggests. I do not at all agree with Dr. Barker that because the inventor says "preferably graphite" any intelligent person would understand that something utterly unlike graphite was also suggested, but on the contrary, I should consider that the preference for graphite indicated rather a preference for materials which were like graphite, such as the gas carbons and artificial carbon pencils well known at that date. Again, I do not understand that a carbon conductor in a V form shown in this patent, has any of the advantages present in the arched form, and therefore I do not consider carbon conductors of a V form referred to in this patent, as in any way suggesting the arch-formed carbons made of fibrous or textile material characteristic of the invention of the patent in suit. One of the most important advantages resulting from the arch form is, that it secures a perfectly uniform distribution of any strain brought upon the conductor by changes of temperature or any other cause, and another is, that it involves a uniform cross-section throughout the conductor, and another is, that it increases the length of the conductor without a corresponding increase in the size of the
enclosing vessel. None of these advantages would exist in
2020 the V-shaped conductor shown in the Konn patent, because
this conductor would be of very irregular cross-section; any
strain brought upon it would be unequally distributed, and its increase in length would be quite insignificant.

I therefore do not find in this patent any anticipation of the patent in suit, as to the character or form of the conductor, and nothing adequate as to the enclosing vessel wholly of glass, since there is nothing in the Konn patent suggesting this feature.

Turning next to the De Moleyns patent No. 9053 of 1841, I find here described a structure which seems to me entirely irrelevant to the present subject. It consists of an exhausted glass globe containing spirals of platinum wire heated by an electric current and an arrangement by which carbon in a condition of fine dust may be made to pour over these coils and glow by heat obtained in falling over them. I believe that this would be entirely inoperative and that the falling of the carbon powder would simply serve more or less to cut off or extinguish the light given by the platinum spirals. But aside from this, it hardly seems necessary to say that such a contrivance has substantially no relation whatever to an invention consisting of an incandescent conductor of an arched form, made out of carbonized fibrous or textile material and enclosed in a chamber wholly of glass.

Finally among these patents I come to that of Binks, No. 119 of

1853. The Binks patent may, I think, be easily disposed of as completely irrelevant, because it describes no form whatever of incandescent electric lamp, but only arc lamps and the electrodes used therein. Still further, the only form of purely carbon electrode, even for an arc lamp, is one formed by subjecting lignite to destructive distillation in closed vessels, by which the patentee says he obtains a hard, close-grained charcoal. The patentee also speaks of forming another sort of electrode by coating metal with tar, pitch, etc., and heating in closed vessels, but these likewise are used, as the patent plainly states, for the production of arc lights, and he also does the like by coating metal with slips or cuttings of charcoal or charcoal veneer. 2021 The fact that this patent contains no reference to incandescent lamps of any sort, would, as it seems to me, dispose of it in relation to the present case, but, as Prof. Brackett seems to think that lignite is not a mineral, and that therefore the production of carbon electrodes, even for the pencils of arc lamp from lignite, has some sort of reference to the use of fibrous textile material for the carbon conductors in incandescent lamps, it may be worth while to mention that, in the opinion of mineralogists, at least, lignite is a mineral despite the fact that, like the diamond and all forms of coal, it is undoubtedly of vegetable origin and contains more or less trace of its original structure.

Referring to Dana's Mineralogy, published in New York, 1877, I find on page 395 the general title "Mineral coal" and on the next page under the same general heading, "C., Brown coal, * * * (lignite.) Brown coal is often called lignite, but this term is sometimes restricted to masses of coal which still retain the form of the original wood."

In a work published by the U. S. Government, entitled "Mineral Resources of the United States," by Albert Williams, Jr., chief of division of mining statistics and technology, I find on page 85 as follows: "Wyoming. * * * In quality the coal is a lignite of superior grade."

It is unnecessary to multiply such references, and I will therefore only say generally that I find lignite referred to everywhere in works on mineralogy, and nowhere in works on botany, which makes me think that it would not naturally suggest the use of vegetable fibrous material to the ordinary intelligent artisan.

I notice another apparent slip or oversight on the part of Prof. Brackett, where, in reference to the Binks patent, he speaks of the thin carbon plates or veneers as being there described as used for incandescent lighting. I do not think he could have read this part of the patent with its context attentively, or he would 2022 have seen that the "electrodes" produced in this manner were clearly intended for use in arc lamps, the only kind anywhere referred to in this patent, and that the idea of their preparation was the same as that involved in the copper plating of arc light electrodes for arc lamps, so generally employed at the present day, viz., the reduction of the resistance of the electrode by the addition of a copper conductor, which Binks proposed to put inside, while in modern practice it is put outside.

Aside from all this, however, it is, I think, manifest at a glance that the Binks patent is no anticipation of the patent in suit, in so far as this patent describes the conductor of an incandescent lamp made of carbonized fibrous or textile material, of an arch shape, and enclosed in an air-tight vessel wholly of glass.

Adjourned till Monday, the 15th inst., at 11 a. m.

NEW YORK, *April* 15, 1889.

Met pursuant to adjournment.

Present: Mr. Curtis for complainant, and Mr. Donnelly for defendant, and the examination of Prof. MORTON was continued as follows:

Witness continues:

At the conclusion of the last session I had gone over all the patents referred to by either Prof. Brackett or Dr. Barker as containing the best of their references as anticipations of the patent in suit. Prof. Brackett refers also to two publications, one being that by Sidot in the Comptes Rendus. This I find to describe a method of carbonization of various materials, including many vegetable fibrous substances by enclosing them in highly heated tubes through which sulphide of carbon is made to pass. The author characterizes the product thus obtained in the following words:

> "It may be characterized from a point of view of conductivity as wood charcoal transformed into coke."

2023 The only reference to electric light in this article is the following:

> "The pencils made of them give an electric light far more intense than the light obtained with carbons from gas retorts."

From all this it will, I think, appear that in this article we have no suggestion whatever as to the use of carbon from vegetable fibre or textile material, made into an arc form, as the conductor of an incandescent electric lamp, but have only information as to a method of converting such materials into coke whereby their utility in replacing the ordinary arc light electrodes, generally made from gas coke, was set forth.

Finally, Prof. Brackett refers to a paper by Violette, published in the American Journal of Science and Arts in 1853. This describes a method of producing a red charcoal, specially fit for the manufacture of gunpowder, by the use of superheated steam. Incidentally the author notices that charcoal made at a high temperature conducts better than the charcoal of gas retorts, and serves better for electric illumination. It is hardly necessary to state that the electric illumination here referred to is arc lighting, carried on by the use of electrodes of gas carbon, and that this article on the preparation of charcoal for gunpowder and its incidental allusion to the improved conductivity of carbon prepared at high temperatures and its consequent usefulness for the electrodes of arc lights, contains no suggestion as to the subject-matter of the patent in suit.

I have now considered all the publications referred to by defendant's experts as being the best in the way of anticipations. As regards the other references to which they have referred in their direct examination, I will not spend the time which would be necessary in order to consider them in detail or individually, but will simply say in general terms that they divide themselves into two classes, the first consisting in scientific papers and researches, which, while developing a great many interesting facts in connection with the properties of carbon and other substances in their 2024 relations to electric currents and the like, do not in any way describe, and are not claimed by anybody to describe, any such structure or combination as constitutes the invention set forth in complainant's patent, and therefore, while these references are interesting as matters of information and to aid in explanation, they have no force and weight whatever if considered in the light of anticipations. The other class consists of patents which either have no reference at all to the subject-matter of the patent in suit; being patents for arc-light regulators, or the manufacture of electrodes for arc lamps, or for incandescent lamps with metallic conductors, or are incandescent lamps with conductors of hard carbon developing properties exactly the reverse of those called for in the invention of the patent in suit. As the experts for defendant have themselves considered these references less complete and appropriate than those which I have recently considered in detail, and as I have shown that not one of these references contains the invention of the patent in suit or anything like it, it seems to me that it would be a waste of time to enumerate these inferior references more particularly, and that it will be enough for me to say that I find them one and all either less relevant, or quite irrelevant to the invention of the patent in suit, as compared with those which I have above discussed individually.

21 Q. Do you agree with the statements made by Professor Cross in his answer to question 5 of his deposition in this case in regard to the meaning of the term "charcoal," in the art of electric lighting prior to 1880?

A. I entirely agree with Professor Cross that in the art of electric lighting prior to this date, the term "charcoal" was commonly used in a generic sense to indicate any sort of carbon used as the electrodes or pencils for the arc electric light. The fact of this use appears from the numerous quotations from patents which Professor Cross has given, and to which some others might be added, and also from the quotations which I myself have referred to in a previous answer. As I also there explained, the origin of this 2025 use of the word is a very simple and natural one, having many analogies. Charcoal being the first substance used to construct these pencils or electrodes for the arc light, the name continued to be used even when the material was changed, as it very soon was, by the substitution of gas carbon or artificially prepared electrodes. We have analogies to this in the use of such terms as that of "chalk," for the material employed in writing or drawing on a blackboard, this material now being, and having been for the last twenty-five years, no longer the mineral substance known as chalk, which is a natural carbonate of lime, but an artificially prepared sulphate of lime. So again the term "steel" is used for an instrument employed to sharpen a carving-knife, even when that instrument is made of china or of some mineral material. The name was at first proper, because the instrument was made of the metal steel. So we speak of a "chandelier," which, of course, strictly means a candle-holder, even though no candles are connected with it, but it is used for gas. So again the term "soda water," is applied to the familiar beverage in the preparation of which soda is no longer used. So again we speak of "galvanized" iron, meaning iron coated with zinc, though no galvanic treatment is now employed in its preparation, the coating being obtained by simple immersion of the iron in a bath of melted zinc. So again the word "pen" is now used for a steel instrument, though originally it meant a quill only, from the latin word *penna*, a quill; and undoubtedly the term "paper" is directly derived from papyrus, although the material paper is an essentially different one in its origin and structure as well as mode of manufacture from papyrus or what would strictly come under the name paper by derivation. The term "lead-pencil" would be another illustration of the same use of a word for a substance to which it was no longer applicable. The "leads," as they are still called, of lead-pencils are in fact made of graphite, which is simply one form of carbon and has absolutely no connection chemically or otherwise with lead.

2026 22 Q. Taking into account this usage in regard to the term "charcoal" in the art of electric lighting, should you say that either the Roberts patent, the Shepard patent, or Lodyguine's publication in the Journal of the Society of Arts referred to by defendant's experts would specifically or primarily indicate to a person skilled in the art as it stood prior to 1880, that carbonized wood in any form was to be employed in the lamps described?

A. I do not think that this word would indicate anything of this character any more than would the word "carbon." It would be in fact the simple equivalent of the word carbon in all respects.

23 Q. Do you agree with the opinion expressed by Professor Barker in his answers to questions 44 and 45, that the Shepard patent describes a semi-incandescent lamp and that a hard or mineral carbon would be superior to one made from a carbonized fibrous or textile material for such a lamp?

A. I entirely agree with Dr. Barker as to both these points.

24 Q. Taking this also into consideration, do you think that a person skilled in the art would understand from reading the Shepard patent that wood charcoal was to be employed, or that any advantages would be gained from the employment of wood charcoal rather than some other form of carbon in the lamp?

A. As I stated in a previous answer I think that the term "prepared charcoal or coke" used in reference to the little cone "D," might suggest that the little cylinder of charcoal enclosed within

the copper tube might be made of wood charcoal or some similar soft form of carbon, which, yielding more readily to the destructive action of such air or gas as might remain in the globe, would exhaust its injurious effect and so tend to preserve the little cone "D," whose preservation would be absolutely essential to the continuous operation of the lamp. This would, of course, only be an inference which might be drawn, and would not amount to anything
2027 like a direction or distinct suggestion that wood carbon was advantageous generally in an incandescent lamp, but, would, on the contrary, be founded on a consideration such as would involve that, for ordinary use in an incandescent lamp, wood charcoal would be undesirable, the supposed desirable feature being one which only existed in this lamp in view of its peculiar construction, by reason of which the destruction of the pencil of wood carbon was to be sought for rather than avoided.

25 Q. In the light of our present knowledge, has carbonized fibrous or textile material as distinguished from other forms of carbon any peculiar fitness for use as the conductor of an incandescent lamp, and if so, in what does such peculiar fitness consist?

A. In the light of our present knowledge we know that to produce such an incandescent lamp as has proved itself to be commercially successful, fibrous vegetable material possesses special advantages, which are, first, that it is readily formed or shaped or may be obtained already formed or shaped prior to carbonization, such forming or shaping including the shaping into an arch form. In the second place, such material after carbonization lends itself readily to the treatment known as "tempering" and "treating," whereby its mechanical strength and uniformity of electric resistance can be readily increased and controlled. Thirdly, such material, after carbonization, is found to have a very high specific electric resistance, which is of great importance and value in the production of an incandescent light although without importance and indeed, on the contrary, an undesirable property in the electrodes employed for an arc light. Fourthly, conductors of this material have been found to possess remarkable properties of mechanical strength enabling them to resist shocks and strains to which they may be exposed, such strength being combined with an elasticity which is specially developed and utilized when their shape is that of the arch or loop. Fifthly, by the use of such fibrous vegetable structures it is comparatively easy to produce conductors which init-ally are of substantially uniform resistance, such uni-
2028 formity being due both to equality of structure and of cross-section throughout their length, and to the purity of their material, namely, the absence of mineral matter, which, being as a rule of high resistance in comparison with carbon, would introduce, if present, great irregularity in this respect.

26 Q. Has carbonized fibrous or textile material, as distinguished from other carbon, any peculiar fitness for use in arc lighting or in semi-incandescent lamps?

A. Not taken as a whole. In other words some of its distinguishing properties would peculiarly unfit it for these uses and would more than neutralize any beneficial effect from such properties as might be advantageous in arc lighting. For example, it is desirable that the specific resistance of the electrodes should be as small as possible. If we could make electrodes with no resistance at all they would be perfect or ideal electrodes for this purpose. Therefore a high specific resistance is in every way an undesirable and injurious property. The capacity of shaping prior to carbonization is of no practical value in connection with arc lights because the materials used for those lights are very readily gotten into shape and usually are so shaped while in the condition of powders already carbonized, or in other words while in the condition of carbon powders.

Their dimensions, also, are such that the question of mechanical strength is entirely immaterial, since their size gives them abundant resistance to any shock to which they would ever be exposed. Uniformity of resistance, in the sense or to the degree in which we consider it in the case of incandescent conductors, is also entirely immaterial in the case of the electrodes for arc lamps, in which such differences, in this respect, as would be serious in the case of incandescent conductors, are quite immaterial. The advantage coming from a purity in the material is one that would have some effect in reference to the electrodes for arc lights, but can be secured in the manufacture of those articles far more readily than by the use of fibrous vegetable material, since pure carbon in the 2029 condition of lamp-black or other preparations, can be readily treated in the manufacture of these electrodes, and will then produce a product quite as pure as anything that can be obtained from vegetable fibre. As these electrodes are never employed in an arch form, of course the capacity of assuming such form would have no value in connection with them.

27 Q. Aside from low specific resistance, what is the quality particularly requisite in arc-light carbons?

A. Resistance to combustion, or, in other words, what we may describe as hardness in this connection. In other words, an extreme density by reason of which, even at very high temperatures the chemical action of the air can have only a minimum effect upon the electrodes.

28 Q. How would carbonized fibrous or textile material comply with this requirement?

A. Very badly as compared with what are known as hard carbons, structures such as those produced from gas coke and the like. One of the reasons why charcoal was very early abandoned as a material for the electrodes of electric lights was just this fact of its rapid combustion or consumption by action of the oxygen of the air, and it was to escape this that even the very early experimenters used pencils of gas coke in place of rods or pieces of wood charcoal.

29 Q. What sort of carbon would best fulfill the requirements of semi-incandescent lamps?

A. In this case also a hard carbon, or just such an one as would be used for arc lights, because here, likewise, the object would be to secure a material of very low specific resistance and of high chemical resistance, as we may call it, or power of resisting the chemical action of the oxygen of the air upon the material.

30 Q. In your answer to question 20, in what sense did you use the expression "superior powers of resistance" as applied to graphite?

A. I meant in that case what I have just called chemical 2030 resistance, that is, resistance to combustion or the attack of oxygen.

31 Q. Would it be practicable in your opinion to conduct the modern commercial business of arc lighting with pencils made of the carbonized fibrous or textile material referred to in the patent in suit?

A. It would not be. Such pencils would have far too high a specific electrical resistance, and far too low a resistance to combustion.

32 Q. Would a person skilled in the art as it stood prior to 1880, or to the making of the invention described and claimed in the patent in suit, have been led naturally from the existing knowledge in regard to arc lights and semi-incandescent lamps to adopt carbonized fibrous or textile material as the conductor of an incandescent lamp?

A. Decidedly not. On the contrary, I think that the state of the art in this respect would have led him in the opposite direction, and would have indicated to him that the desirable thing was a carbon possessing the characteristic properties of what I have indicated by the term "hard carbon," or such as is produced from gas coke and like materials.

33 Q. Assuming that the prior patents and publications referred to by defendant's experts contain instructions to make the incandescent conductor of an electric lamp of wood charcoal, would this in your opinion be equivalent to, or lead to the same result, as the instructions contained in the patent in suit? You may assume for the purposes of your answer that the instructions of the patent in suit are simply to make the conductor of carbonized fibrous or textile material.

A. I do not consider that the instruction to make the conductor of wood charcoal would in any way be the equivalent of the instruction in the patent in suit to make the conductor of carbonized fibrous or textile material, and the following of such instructions would lead, I think, to entirely different results. That is, 2031 the instruction to make the conductor of wood charcoal would cause the artisan following such instruction to go, as I may say, to the charcoal barrel or charcoal bin and select from that material such a piece as he might find best suited to his purpose. He would then proceed to shape such a piece of charcoal in the best manner he could, and he would, I think, have great difficulty in producing any conductor sufficiently uniform in electric resistance to be available in an incandescent electric lamp. I do not see how under any circumstances he could make a conductor having the arched form which would be at all available. On the other hand, the artisan to whom the instruction had been given to produce the conductor from fibrous or textile material would naturally and at once seek out among the uniform fibrous or textile materials such as appeared suited for the purpose, namely, as I have already pointed out, he would take pieces of cotton or linen thread, or of grass-like or reed-like materials, such as he would be familiar with as used in textile structures. These he would find it easy to shape into conductors which, on carbonization in the usual manner, would be substantially uniform in electric resistance, and nothing would be easier than the shaping of such material into an arched form. Therefore it seems to me that the instructions referred to would be entirely different, and would lead to results radically unlike.

34 Q. Professor Brackett states, in his answer to question 5, that the advantages of the arch or horseshoe form of incandescent conductor are present whatever may be the material, whether it is a metal or carbon. Are you of the same opinion?

A. I do not at all agree with Professor Brackett, but on the contrary feel confident that the advantages of the arch form would only be fully or adequately realized in such a material as the patent in suit indicates, namely, carbonized fibrous or textile material. Thus, for example, if the conductor were of metal, its natural flexibility and elasticity would be such as to allow it to bend or change its form without injury, even if it were not originally made into
2032 an arch-shaped form, and therefore the beneficial effect of the arch form as relieving the strain would not be utilized or realized. On the other hand, if the material were hard carbon, then on account of the brittleness of that substance the strains produced by expansion might be likely to cause fracture in the arch form quite as much as, or more than, in the form of a straight pencil, because in the case of a straight pencil the expansion and contraction would force a yielding or movement on the part of the supports, and would be equally distributed through the conductor, whereas, when this conductor was in an arched form, the same strain would have more tendency to rupture the arch than it would to move the supports in the previous case. If, however, the material were such carbon as is produced by the carbonization of a fibrous or textile material, then this material having in itself considerable elasticity and flexibility, would, if made into an arch form, so yield that the strains produced by heating and cooling would be equally distributed and produce no injurious effect such as would result with the same material if it were not in an arched form, when its flexibility would be likely to result in a buckling or sudden bending at a single point or a few points, by which excessive strain would be developed at those points, and tend to cause fracture. It is therefore my opinion that the valuable results obtained from the arched form, as far as the question of distribution and strain is concerned, would only be adequately realized by the fibrous material indicated in the patent and not either by a metallic conductor or one made of hard carbon.

35, 36 Q. Do you agree with the opinion expressed by defendant's experts that the advantages of the arch form in providing for expansion and contraction are not present in the lamp described in the patent in suit, but that the conductor there shown and described is as liable to fracture in the arch form shown as it would be in the form of a straight rod or pencil?

2033 A. I do not agree with them, if it is understood, as of course it should be, that the material of the conductor shown in the patent is the carbonized fibrous material. In that case, even in the form shown in the patent drawing, such material would have sufficient elasticity to derive beneficial effect from the arched form as there shown. Of course I do not understand that the patent in its description at all confines itself to what I may call so low an arch as that shown in the drawing. On the contrary, the patent itself speaks of this arch as being of an arch or horsehoe shape and also as being an arch or loop.

37 Q. Do you agree with Professor Brackett in the opinion expressed by him in answer to question 35 that in the modern incandescent lamp the advantages arising from the capacity of the conductor to contract and expand without breaking or disturbing the position of the fixed terminals, would be present whatever the form of the conductor, whether that of a loop or of a straight piece?

A. I do not. On the contrary, I feel sure that if, in a modern lamp, the conductor were arranged in a straight piece it would be very liable to be broken, because on expanding it would be liable to buckle or bend substantially at one point, or on shrinking be subjected to a strain which would fracture it by tension.

38 Q. The patentees, in the specification of the patent in suit, say that they have used conductors or burners of various shapes such as an inverted-V-shaped burner, and conductors of varying contours, with rectangular bends instead of curvilinear ones, but that they prefer the arch shape. As a matter of fact, are the other forms here referred to the equivalent of the preferred form or arch shape, so far as providing for expansion and contraction is concerned?

A. They are not, as a matter of fact, to any adequate degree, and would only be equivalent to the arch form as regards certain other advantages resulting from its use, such as the greater length of conductor which could be contained within an enclosing vessel of a given size.

2034 39 Q. Do you agree with Professor Barker that the inverted-V-shape burner here referred to is a semi-incandescent lamp?

A. I do not. The whole contest makes it perfectly plain that the reference here is simply to different shapes of a continuous conductor, and not to a radically different structure which would bring the lamp into a different class.

40 Q. Was the liability of the carbon conductor to fracture from the effects of expansion and contraction a recognized defect of the incandescent lamps having straight carbon conductors, which were known prior to 1880?

A. It was; and means of correcting this defect are set forth in some of the patents which have been referred to.

41 Q. What kind of means?

A. Arrangements as to the supports of the ends of the conductors by which these were made to yield so as to accommodate themselves to changes in length of the conductor.

42 Q. Do you know of any incandescent lamps used since 1880 having straight carbons, V-shaped carbons, or carbons of any shape except the arch shape or some modification of it?

A. I know of none except such as would come within the description of modified arch shape; such, for instance, as the Maxim lamps which were made with a paper carbon having the general shape of the letter "M," but so constructed that there were actually three arches in the conductor, the bends being rounded or arch shaped.

43 Q. Do you agree with Professor Brackett in the opinion expressed in his answer to question 6, and Professor Barker in the opinion he expresses in his answer to question 14, that the arch or horseshoe shape described and claimed in the patent in suit was old in carbon? Please consider in this connection Professor Brackett's answers to questions 5 and 9, and Professor Barker's answers to cross-questions 64 and 65.

2035 A. I do not agree with these gentlemen. The only reference that either of them is able to cite is that of the Konn patents, in which there is described a carbon conductor in a V shape, the V shape shown in the drawing being a very low or flat "V," that is, having a very wide angle at the apex, and of irregular cross-section. This I do not think in any way even approaches the suggestion of an arch shape or if it were followed would produce a conductor having any of the beneficial properties resulting from such arch shape. In addition to this state of affairs, which appears from the drawing, the Konn patent No. 3809 states that the light is formed at the angle at the bottom of the "V." This would indicate either that the cross-section of the "V" were extremely irregular, or that in some way there was a special resistance at this point by reason of which the light was there locally developed, and of course any such conditions would be inconsistent with the beneficial effects obtainable from an arched shape, such as is indicated in the patent in suit.

44 Q. Do you agree with Mr. Edison in the opinion he expresses in his answers to questions 432 and 467 to 470 inclusive, that while the quality of high specific resistance possessed by carbonized fibrous or textile material is advantageous for lamps of high resistance, it is not advantageous but rather the reverse for incandescent lamps of comparatively low resistance?

A. I do not at all agree with this statement, and was very much astonished when I first read it in Mr. Edison's deposition, and feel convinced that he could not have given much thought to what he was saying when he made this answer. In any system of electric lighting by incandescence it is desirable that as much of the resistance of the entire circuit as possible should be concentrated in the incandescent conductors of the lamp. Where these lamps are to be employed in parallel arc, it is important that the total resistance of each lamp should be very high, but when the lamps are used in series, it is desirable that the total resistance of each lamp should be relatively low; but, 2036 since the production of light must in all cases be proportional to the product, involving the resistance as one factor and the current as another, it is manifest that the specific resistance must in either case be high in order that there should be enough of it in a moderate length of the conductor to develop from the current employed the light energy which is desired. If, as Mr. Edison states, a high specific resistance was undesirable in an incandescent lamp when used in successive series, then, of course, such lamps might readily be made by the use of good conductors, such as the ordinary arc-light electrodes. The actual fact is that a high specific resistance is desirable in either form of lamp, and all that can truly be said in this regard as to difference, is that it is more important in order to meet certain mechanical conditions in the case of the lamps run in parallel series than it is with the lamps run in successive series. So far, there is a difference, but this is simply a difference of degree, and does not authorize any such broad statement as that which is contained in Mr. Edison's answers referred to.

45 Q. As a matter of fact, what sort of carbon is used in series lamps of relatively low total resistance which are in commercial use at present?

A. Exactly the same kind of carbon as is used in the lamps of high resistance, the difference being that the conductors are made shorter and thicker in the lamps of low resistance, and longer and thinner in the lamps of high resistance.

46 Q. Is it hard carbon or carbonized fibrous or textile material?

A. Carbonized fibrous or textile material.

47 Q. Please read Prof. Cross's answer to question 33, and state whether or not you agree with him in the opinion he expresses that none of the prior patents and publications put in evidence by the defendant describe or show the lamp structure of complainant's patent in suit, or any equivalent for it?

2037 A. I entirely agree with Prof. Cross in this answer, and, as I have already pointed out in great detail, I find in none of the patents or publications referred to by defendant's experts, except, of course, in the prior patents of Sawyer and Man referred to in the patent in suit, this part of the combination or invention set forth in that patent.

48 Q. Do you agree with the opinion expressed by defendant's experts that the lamp structure of the complainant's patent in suit has all the defects of the lamp structures of incandescent lamps described in the prior patents and publications in evidence, and that the said lamp structure would be wholly unsuitable for making a practically useful lamp for the purpose of electric illumination, and, moreover, that the low resistance of the incandescent conductor described in complainant's patent would make the lamp practically useless?

A. I do not agree with this opinion, but on the contrary, consider that the lamp structure of complainant's patent, by reason of its consisting wholly of glass, avoids serious defects found in previous structures, and is capable of producing a practically efficient incandescent electric lamp.

49 Q. Would it in your opinion be practically useful for any commercial purpose, and how would it in your opinion compare with such lamps as are described in the prior patents and publications put in evidence?

A. It would undoubtedly be useful for commercial purposes at the date of its invention, though of course it might not compete at the present day with the improved lamps now made. It would, I have no doubt, be very superior to any of the lamps made or described prior to the date of complainant's patent, though some of these, I believe, actually met with a certain amount of commercial success. Thus, for example, in the work entitled "Electric Lighting," by Hyppolite Fontaine, translated from the French by Paget Higgs, London, 1878, I find, on page 171, a reference to the
2038 Ladyguine lamp and to certain improvements made thereupon by Mr. Konn, also of St. Petersburg. On page 174 in reference to these the following statement occurs:

"Three of these lamps were introduced two years ago at the house of M. Florent, a merchant of St. Petersburg, and put in action with an 'Alliance' machine. Each carbon lasts about two hours with the exception of the first, which is consumed nearly immediately; the light is very agreeable, but its cost considerably exceeds that of gas. M. Florent, whom we have had occasion several times to see, has informed us that the great advantage he has found in the employment of electric lighting was its cleanliness. His storerooms contain much white linen that gas rapidly*ly* impairs and on which electricity exercises no injurious influence. The bleaching economized fully compensates the supplementary cost necessitated by an important introduction with but little regard to the light obtained."

It is manifest from this that, if a lamp in which the carbon only lasted two hours had a commercial value at this time in St. Petersburg, a lamp, such as that described in complainant's patent, which undoubtedly would last for 100 or 200 hours, would, under like conditions, have very much greater commercial value, and I see no reason why with the exercise of ordinary ingenuity and experience such as any workman acquires in the construction of apparatus, lamps such as those described in complainant's patent should not be made to last many times as long as I have indicated.

50 Q. Do you agree with the opinion expressed by defendant's experts that the inventors, Sawyer and Man, made no substantial advance in the art, or at least none that is shown and described in the patent in suit?

A. I do not. On the contrary I think that they made a very important contribution to the state of the art, this contribution consisting in the *the* introduction of a lamp having its carbon
2039 conductor made of fibrous or textile material, of an arch shape, and enclosed in an air-tight vessel constructed wholly of glass.

51 Q. Do you agree with defendant's experts that in view of

the prior patents and publications put in evidence by defendant, there is no patentable novelty in the inventions referred to in the first, second and fourth claims of the patent in suit?

A. I do not. On the contrary I think that those patents and publications show that the state of the art was far from anticipating the invention of this patent, and was really going in an opposite direction, and, so far from suggesting the combinations involved in this patent, rather suggested an opposite and different development which would have led away from the result here secured. As regards the first claim, there was nothing in the state of the art suggesting the production of an incandescent conductor for an electric lamp made from carbonized fibrous or textile material in any shape, and certainly not in an arch or horseshoe shape. Having reference to the second claim, there is nothing in the state of the art showing the combination of an incandescing conductor of carbonized fibrous material enclosed in a transparent, hermetically sealed chamber; and, as regards the fourth claim, there is nothing in the state of the art showing the combination of a chamber made wholly of glass from which all carbon-consuming gas has been exhausted or driven, electric conductors passing through the glass walls of said chamber and hermetically sealed therein, and an illuminating conductor consisting of carbon made from a fibrous or textile material having the form of an arch or loop.

52 Q. Do you agree with the defendant's experts, that the material and the form of the burner of the first claim are entirely independent of each other?

A. I do not. On the contrary, as I have already pointed out, I consider that the material and form are two elements which acting together produce a novel and useful result which would not be obtained or availed of where either of them existed separately. That is, the arch form would be of little or no value if the conductor were of metal or of hard carbon, and the fibrous or textile material would be of much less utility if employed in a conductor not having the arch form. 2040

53 Q. Do you agree with defendant's experts that there is no combination between the particular kind of burner referred to in the fourth claim and the enclosing chamber made entirely of glass, referred to in the same claim?

A. I do not. On the contrary, I consider that hereby we get a result by the concordant action of two elements, which result requires for its development the united effect of both elements. Thus, the conductor of fibrous material here described, in order to render available the special advantages which it possesses, must be protected very thoroughly from the access of air, and therefore must be enclosed within a chamber wholly of glass, by which means alone such thorough protection would be attainable.

54 Q. Defendant's experts express the opinion that in order to make the incandescent lamp at all practical for any useful purpose, a radically new departure was necessary, which consisted essentially in making the incandescent conductor of very high resistance, so that the requisite amount of electrical energy would be conveyed to

it on small wires which could be sealed into the glass, and that this radically new departure was first disclosed in the "Herald" article in evidence, and in Mr. Edison's patent No. 223,898. Do you agree with them in this opinion?

A. I do not. As regards the novelty of the idea that incandescent lamps should be made with conductors of very high resistance, this does not originate with Mr. Edison because it is shown in a series of patents taken out by Lane-Fox in England in 1878 and the early part of 1879. The patents are respectively numbered 3988, 4043 and 4626 of 1878, and 1122 of 1879. They show and explain a system in which incandescent electric lamps were 2041 to be used with very long conductors of fine platinum wire sealed into glass vessels, and, curiously enough, the electro-motive force necessary to run these lamps is stated to be 100 volts, which is exactly the electro-motive force which was stated by Mr. Edison to be the desirable one, and just about that actually used to-day by his company in their lamps run in parallel arc.

Adjourned to Tuesday, April 16th, 1889, at 11 a. m.

The four patents of Lane-Fox to which I have referred form a very remarkable series when we consider their date and the completeness of the system which they express. They show that their author had clearly and prominently in his mind all the general conditions which experience has proved to be desirable in a practical application of electricity for domestic lighting. Taking them in their order, for example, we have, first, that of October 9th, 1878, where, in the provisional specification, we have fully set forth a method of parallel arc distribution such as would be carried out in lighting up a town and the necessity of a high electro-motive force which implies a correspondingly high resistance in the incandescent lamps. This last is stated in the following words: "The electro-motive force of the electric conducting mains should be kept as nearly as possible constant at say 100 volts or British Association units of electro-motive force."

In the specification as issued, we find also as follows.

"In order to produce a light, I pass the electric current through a thin strip or wire of some suitable material for the purpose. I prefer to use an alloy of platinum and iridium. The electric lamp in which the light is produced therefore consists of two conductors insulated from one another, having this strip or wire between them and in contact with each.

"The material or alloy employed should be capable of standing as high a degree of temperature as possible without fusing, volatilizing or falling to pieces. It should also have a high specific 2042 resistance. The higher the temperature to which the material can be raised, the more economical will be the light produced, that is, the light will be greater in proportion to the force or energy expended, inasmuch as the radiant energy proceeding from the surface of the material will be more and more luminous as the temperature increases.

"In order that the electric force may be conveyed at a high tension, that is, have high electro-motive force so that there may not be very great loss from the resistance of the conducting mains or conductors, I make the lamp which I use of an alloy of platinum and ir*r*idium of lengths of fine wire so that I may get high resistance without having a large extent of luminous surface."

In this patent, at figures 1 and 2, are shown drawings of lamps in which glass chambers are represented, through the substance of which the conductors are passed and then terminate in very long fine wires, which by their incandescence, on being heated, develop the desired light.

The next patent is dated October 12th, 1878. In this patent I find in the specification the following statement:

"Figures 1 and 2 of the annexed drawings represent an electric lamp in which the luminous surface which I will term the bridge, is made of asbestos or similar non-conducting material saturated or impregnated with some refractory conducting material such as carbon or ir*r*idium. A, is the bridge held up by metal chips, B B, which are attached to the conductors C C. These conductors pass through the top D, of a flask E, which is hermetically sealed and is filled with nitrogen gas. The luminous portion, *a* to *a'*, of the bridge is of higher resistance than the rest."

The drawings 1 and 2 show structures which in appearance are remarkably like many of the incandescent electric lamps of to-day.

The next patent is dated November 14th, 1878. In the provisional specification, near the beginning, I find as follows:

2043 "In order to obtain light from an electric current I make use of a sheet of platinized or ir*r*idized or carbonized asbestos or other suitable material supported between two conducting terminals of platinum or other suitable material; and in order to preserve the incandescent substance in a good condition and prevent its deterioration, I enclose the whole in a glass or other suitable transparent vessel or cover *through which the platinum supports are fused*." (The italics are my own.) "This vessel or cover is then exhausted of air by means of a small tube leading from it and it may then, if thought desirable, be filled with some gas or vapor which has no action on the material used for producing the light. * * * The length and thickness of the spiral will depend on the intensity of the light required and the electro-motive force available. The ends of the spiral should be united to these wires with some hard solder. The spiral is then enclosed in a globe or flask-shaped glass vessel whose neck is sufficiently large to admit it, and the neck should then be closed up round the different supporting wires so as to seal them in and make the whole vessel air tight. A small tube projecting from some part of the neck, is then connected with a Sprengel air pump or other exhausting apparatus. The air is the*m* removed as completely as possible and the tube sealed up, some gas being previously admitted, if desired into the vessel, as before described. The neck of the vessel may be fixed to some suitable holder or support, and the projecting platinum wires should be connected to proper terminals.

"According to another method or arrangement for obtaining light by the incandescence of carbon or other suitable material, the said material is enclosed as before described in a glass vessel from which the air is exhausted or which is filled with any suitable gas and the terminals are, as before described, fused into the glass vessel at the lower end of the neck when it is sealed up; or the glass may be made in any way by which it can be readily opened when desired and be again hermetically sealed."

2044 This patent also contains full directions as to the laying of main wires and distribution of currents through a town district, and also shows means for measuring and regulating the flow of electricity.

Lastly, the fourth patent, dated March 20th, 1879, of which there is only a provisional specification. In this document a method is described of preparing incandescent conductors which are to be used in such a system of lighting as has been described in previous patents, the materials to be employed being plumbago, as a good conductor, and magnesia, zirconia, or the like, as a bad conductor. Such materials are to be mixed in such proportions as will give a specific resistance in accordance with the electro-motive force employed in producing the light. An electro-motive force of 140 volts is alluded to, and a resistance of 300 ohms, or British Association units is likewise spoken of. The method of mixing and forming these materials into incandescent conductors is then described at some length, and finally I find the following statement:

"The parts before described are hermetically enclosed within a globe or other form of glass or other suitable material, through one portion of which the conducting wires are hermetically carried. From this globe all trace of oxygen, carbonic acid gas, water and any gas, or vapor capable of attacking or affecting the materials of the luminous bridge when at a high temperature must be removed."

Turning to what Dr. Barker says in the last paragraph of his answer 3, when recalled, and in his answer 4, it appears that all the features which he sets forth in these answers as characterizing what he has called the "radical new departure" in the method of constructing incandescent electric lamps, and which he there attributes to Mr. Edison, are found fully developed in this series of patents of Lane-Fox which considerably anticipated the date of the Herald article and the two Edison patents referred to by defendant's experts.

2045 Referring to what Dr. Barker says about this new departure, I should say that while it was quite true that the conditions he has mentioned were of the greatest importance in the process of incandescent lighting in parallel arc, they played no such part in the process of electric lighting in successive series, and therefore this should be borne in mind, lest an erroneous impression might arise from giving attention exclusively to one method, and omitting the other.

55 Q. Is it necessary in your opinion, that the conductor would be made of very high resistance, as stated by defendant's experts, in order to make a successful incandescent lamp, even according to modern standards?

A. It is certainly not, where the lamps are to be used in successive series.

56 Q. Are incandescent lamps used commercially in that way at the present time?

A. They are, very extensively.

57 Q. Would the series lamps so used, such as the Thompson-Houston, the Bernstein, and the Heissler, to which you have referred, come within Dr. Barker's definition of the alleged radical new departure, as lamps in which the necessary electric energy required to give the light is conveyed to the lamp in the form of a maximum of tension and a minimum of current?

A. They would not, since, as a matter of fact, their resistance is very low, and the current strength employed with them relatively very large.

58 Q. Do you agree with the opinions expressed by Dr. Barker in his answers to questions 2 and 3, when recalled, that the Geissler tube construction of chamber was not, and has not at any time been, known as a substitute or equivalent for the enclosing chamber of electric lamps like that shown and described in the patent in suit, and that the Geissler tube construction of chamber is not applicable to, or useful in, the construction of lamps like that described in the patent in suit, or of any incandescent lamps 2046 that were known prior to the publication of Mr. Edison's lamp construction in December, 1879?

A. I do not agree with Dr. Barker, because, in the first place, the Geissler tube construction, as applied to an incandescent lamp, was substantially shown as long ago as in the King lamp, where the upper terminal of the incandescent conductor was attached to a platinum wire fused, or hermetically sealed, through the upper end of the glass chamber. The Geissler tube construction is also fully and completely pointed out in the Lane-Fox patents to which I have recently referred; and in one or more of Prof. Crookes's radiometer experiments, an arrangement was used which was, in effect, an incandescent electric lamp of precisely and exactly what we understand as the Geissler tube construction. One of these structures is shown and described in the Philosophical Transactions for 1874, page 513, and another in the Philosophical Transactions for 1876, page 351. The first of these structures is very closely like that of the patent in suit, and the second completely that of the Geissler tube. The substantial equivalency of these two methods, as well as the advantage of the Geissler tube structure over the other, is fully recognized in these papers of Dr. Crookes's, as for example, in the following passage in the Philosophical Transactions for 1876, page 520:

"83. The cement which I have found best for keeping a vacuum is made by using together eight parts of white rosin and three parts of beeswax. For two hours this cements perfectly, but at the highest exhaustion it leaks in the course of a day or two. Ordinary or vulcanized India-rubber joints are of no use in these experiments, as with the vacuum they allow oxygenized air to pass through as quickly as the pump will take it up. Whenever possible, the glass tube should be united by fusion, and where this is impracticable, mercury joints should be used."

I think Dr. Barker must have overlooked the existence of these various prior publications when he says that he does not know that the Geissler tube construction of chamber was, or is, or has 2047 at any time been, found as a substitute or equivalent for the enclosing chamber of electric lamps like that shown and described in the patent in suit. I also do not agree with him as to his opinion that the Geissler tube construction would not be applicable or useful in such an incandescent lamp as is shown in the patent — suit, for, in my opinion, any good glass-blower would have no difficulty in construing a lamp having all the substantial characteristics of the features shown in the patent in suit, in the Geissler tube manner; or, in other words, by sealing the conductors directly into the walls of the chamber, sealing the different parts of the chamber directly to each other, and applying an exhausting tube which could be hermetically closed or sealed off after the lamp was finished.

59 Q. In his answer to cross-questions 5 and 6, Prof. Barker says in substance that he thinks that a wire a millimeter in diameter is the largest size which could be successfully sealed into the glass in regular commercial work. In other parts of his examination he says that he does not think that this would be of sufficient size to convey the current for such carbons as were used in incandescent lamps made prior to 1880. What is your opinion in regard to this?

A. I do not agree with Dr. Barker, as to this matter for the following reasons: Carbons of 1¾ millimeters and 2 millimeters in thickness, appear to have been used in incandescent electric lamps as early as 1874, as I judge from an article in the Telegraphic Journal and Electrical Review, published in London, May 25th, 1874. Now as the conducting power of platinum is many hundred times as great as that of carbon, it is manifest that a platinum wire one millimeter in diameter would readily carry sufficient current to heat to incandescence a carbon rod whose diameter was only about twice as great, without risk of the platinum wire being itself unduly heated.

60 Q. Defendant's experts say that they do not think that it would be practicable either to seal on the base plate of the lamp of the patent in suit by fusion of the glass, or to seal the conductors 2048 into the glass by fusion. What is your opinion in regard to this? Please read Prof. Barker's answers to Q. 20 and 21, and Prof. Brackett's answers to Q. 13 and 14 and X Q. 86 to 100, inclusive, and X Q. 108 to 117, as well as his testimony when recalled?

A. It is manifest that these gentlemen have founded their opinion on the assumption that the details of the structure as represented in the drawings of the patent were to be literally followed as to such points as the precise thickness of the glass, the flatness of the base plate, and the size, shape and material of the conductors. If these assumptions were correct, their conclusions would be legitimate, but of course any intelligent glass-blower would know that when he desired to seal conductors directly through glass, those conductors must be made of platinum and of moderate dimensions; also, that when two portions of a glass chamber were to be sealed together, their thickness must likewise be moderate and that a large flat surface must be avoided when the glass of which it was made was thin, by replacing it with a curved surface, by which its resistance to atmospheric pressure would be made adequate. With such modifications as these, which would present themselves as matters of course to any skilled glass-blower, there would be, I am confident, no difficulty whatever in making a structure which would be, in all essential or substantial particulars, the same as that shown in the patent in suit, by the Geissler tube method, that is, by sealing the conductors directly through the glass and uniting the parts of the chamber to each other by fusion I have in my own possession many Geissler tubes very much larger than the chamber of the lamp represented in the patent in suit, which have evidently been produced by the usual Geissler tube method, and which have maintained their vacuum entirely unimpaired for twelve years or more.

61 Q. Of what sort of carbon would the preferred form of the filament described in the Edison patent No. 223,898, put in evidence by defendant, be composed?

A. Hard carbon, or such as I have described by that name,
2049 that is, such carbon as was formerly manufactured and used
for the electrodes of arc lamps. The preferred form described in this patent No. 223,898 of 1880, is made by preparing a putty-like mixture of lamp-black and coal tar and then taking this into a helix and carbonizing it in a closed crucible. This would be in material and mode of preparation precisely identical with the arc-light carbons which have been described in a number of the patents and publications already introduced and frequently referred to in this case.

62 Q. Has the Edison Company, or any one else so far as you know, made use of this kind of carbon in commercial incandescent lamps since 1880?

A. Not to my knowledge.

63 Q. Are you familiar with the different styles of incandescent lamps in commercial use in this country?

A. I am.

64 Q. What sort of carbon has been used in the Edison lamps which have been put into commercial use?

A. As far as I am aware, carbon made from bamboo only, except in the case of the steamship "Columbia" built for the Oregon Railway and Navigation Company, on which I saw incandescent lamps furnished by the Edison Company and made with paper carbons.

65 Q. Referring now to the testimony of defendant's experts in regard to the structure and general peculiarities of fibrous materials; were the various peculiarities which they describe known prior to 1880 or have they been discovered since?

A. They were all known prior to 1880.

66 Q. Were the general characteristics of the structure of bamboo known prior to 1880?

A. They were.

67 Q. Was it known that the structure of bamboo was very dense and homogeneous, and that its fibres were parallel, so that it could be readily split into very fine strips without cutting across the fibres?

A. It was.

2050 68 Q. Prof. Barker says in his answer to question 15, that bamboo is not a material properly called textile; that he has never heard of its being used as such for textile purposes or for the manufacture of paper or any textile fabric, and Prof. Brackett says in his answer to question 1, when recalled, that bamboo is quite unsuited to be either spun or woven or to be made into paper. What is your opinion in regard to this?

A. My opinion as to these answers is, that they show a remarkable lack of general information such as would be acquired from encyclopedias and books bearing on such subjects more particularly. As a matter of fact, if there is one substance rather than another which particularly connects itself with the manufacture of paper, that substance is bamboo. The earliest paper of the world which deserves the name of paper strictly, namely, a product made by reducing vegetable fibre to a pulp diffused in water and then obtaining from this a sheet by the well-known method of the paper-maker, appears to have been made in China from bamboo, and is there so made at the present moment. The finest quality of paper, namely, what is known as "India paper," used for the production of proof impressions from steel engravings and the like, is stated to be manufactured from bamboo. I have made a series of extracts from different publications which I here submit, which show that bamboo is used in China for almost every conceivable purpose, including the manufacture of paper and numerous textile fabrics, such as cordage for boats, sails, baskets, bedding and the like. In this connection it may be interesting to refer to a few samples of textile or woven fabrics made from bamboo, which I obtained a few days since from Vantine, Chinese importer and dealer in New York, and here submit. One of them is a sort of tray in which the border as well as the rest appears to be made of split bamboo, the portion used in the border, being, I judge, identical with that employed by the Edison Company in the manufacture of their incandescent lamps, 2051 that is, the material inside of the hard silicious bark or outer surface. Another is an egg-shaped basket made of very fine fibres interwoven, and the third a small basket made of thicker strips, all being of the same substance, namely, the fibrous structure of the bamboo split into thin filaments. There are also a number of United States patents describing the preparation of bamboo so that its fibres may be used in the manufacture of paper or for textile purposes generally. These patents are:

No. 41627, February 16th, 1864, to Philip Lichtenstadt.

No. 68363, September 3d, 1867, to Charles Heaton.

No. 70474, November 5th, 1867, to Robert W. Russell and Thomas Howland.

No. 87295, February 23d, 1869, to Louis S. Robbins and John A. Southmayd.

69 Q. Should you consider such structures as the baskets and other articles to which you have referred, and of which you have produced samples, textile fabrics?

A. Certainly. The word textile comes from the Latin *texto*, "I weave," and means woven. Weaving in its earlier stages was a process of interlacing strips or fibres such as is exhibited in these baskets, and is seen in mats and other like products.

70 Q. Do you understand that the use of comparatively fine strips of bamboo for weaving baskets and such objects was common prior to 1880?

A. Extremely common. I imagine there are few households, where some article of this sort does not exist.

71 Q. Prof. Barker in his answer to question 50 says that the reference to electric light in the Guaduin patent, in his opinion, includes the incandescent light as well as the arc light, as both forms were well known at that time. Do you agree with him in this?

A. I do not at all agree with Dr. Barker, because, though it is true that some incandescent electric lamps had been made and exhibited as early as 1876, the art had certainly reached no 2052 such development as would warrant its being referred to in the manner found in this patent. The words of the patent are "for the manufacture of pencils for electric lighting." This would clearly and directly convey the idea that the electric lighting referred to, was a well-known commercial business. This was true at the date named, of arc lighting, but not at all of incandescent light*n*ing.

72 Q. What sort of carbon would be produced by the process described in the Gauduin certificate of edition of April 7th, 1877, and would it, in your opinion, be substantially the same as the carbonized fibrous or textile material of the complainant's patent in suit?

A. The words of the patent referring to this matter, are as follows: "I convert this wooden object into a hard and compact carbon, conserving its primitive form, by drying it, suitably impregnating it with tar, pitch, bitumen, rosin, essence and oils of coal, in carbon of hydrogen, sugar, carmel, or other matters possessing anal*a*gous properties. I distill it slowly so as to expel the volatile bodies; I impregnate it anew and redistill it as many times as necessary, and finally heat it to a high degree of temperature in a reductive atmosphere."

The product produced in this way would be substantially hard carbon, such as was used from an early period for the electrodes of arc lights, and would have in it nothing peculiar to, or characteristic of, the wood from which it was only in small part formed. It would certainly have none of the properties which would characterize the product of complainant's patent, namely a carbon conductor made from vegetable, fibrous or textile material.

73 Q. Referring now to the description of the Ladyguine lamp in

the London Journal of the Society of Arts, what kind of carbon do the contemporary publications show to have been used by Ladyguine and his associates in their lamps?

A. The material, I think, was plainly the hard carbon
2053 made from gas coke and the like, commonly used for the
electrodes of arc lamps, and this, I think, appears very clearly from the statement of the contemporary patents taken out by the members of the firm of Kosloff & Co., mentioned in this article as those who are interested in this lamp, these patents appearing in the name of Konn and Kosloff. These patents are fully referred to by Prof. Cross in his answer to Q. 7, and I will therefore not repeat what has been already sufficiently explained. In the translation of Fontaine by Paget Higgs, published in 1878, to which I have already referred, I find the following on page 172: "M. Ladyguine was the first who had the idea of replacing the platinum wire in these combustion experiments by small bars of carbon (coke) anal*a*gous to graphite, that is to say a good conductor, and thus resolve the problem of electric lighting."

These conductors are then repeatedly referred to as "carbon" until near the foot of the next page, where I find this expression: "The retort carbons, E, to the number of five, are placed between two small plates which crown the rods."

This very clearly indicates that the carbon used in these experiments and exhibitions was hard carbon, to which I have above referred.

In reference to the same experiments, in the Telegraphic Journal of May 25th, 1874, the conductors of the lamps are constantly referred to as "carbon rods," which I think conveys clearly the same impression.

74 Q. Prof. Barker says he thinks the stopper of the globe of the Shepard patent must have been made of glass. Do you find anything in the Shepard patent which indicates whether the material of the stopper was glass or not?

A. Yes, I find a reference to the fact that the wires passed through it must be insulated, which clearly implies that it was not glass, since insulation would be entirely unnecessary in that case. The words are:

"The stopper B, of this globe, is very carefully luted, and
2054 two insulated polar wires, P and N, of about 2 millimeters in
diameter, are passed through it."

Adjourned to Thursday, April 18th, 1889, at 10.30 a. m.

NEW YORK, *April 18th*, 1889.

Met and adjourned till Monday, the 22d inst., at 10.30 a. m.

NEW YORK, *April* 22, 1889.

Met pursuant to adjournment. Present, Mr. Curtis for complainant, and Mr. Dyer and Mr. Donnelly for defendant.

Complainant's counsel offers in evidence Blue Book copies of British patents granted to St. George Lane Fox, No. 3988, dated October

9, 1878; No. 4043, dated October 12, 1878; No. 4626, dated November 13, 1878; and No. 1122, dated March 20, 1879; and the same are marked respectively "Complainant's Exhibits Lane Fox British Patent No. 3988, of 1878;" "No. 4043, of 1878;" "No. 4626, of 1878;" and "No. 1122, of 1879."

Defendant's counsel admits that the original Blue Books of each of the said British patents were published in 1879, but not earlier than six months after their respective dates, and consents to the use of a typewriter copy of the patent No. 4626 of 1878 in place of the Blue Book, subject to the correction of any errors that may be found therein.

2055 Complainant's counsel also offers in evidence pages 513 and 514 of the Philosophical Transactions of the Royal Society of London for 1874, published at London in the same year, and the same is marked "Complainant's Exhibit Philosophical Transactions No. 1;" also sections 171 to 177, inclusive, on pages 350 to 352 of the same publication for 1876, published at London in 1877, and the same is marked "Complainant's Exhibit Philosophical Transactions No. 2." It is agreed that a copy of said extracts may be used in place of the original books, subject to the correction of any errors that may be found therein.

Complainant's counsel also offers in evidence the various extracts from publications produced by Dr. Morton and referred to in his answer to question 68 as follows:

The Penny Encyclopedia, vol. 17, p. 207, which is marked "Complainant's Exhibit, Penny Encyclopedia Extract;" Chambers' Encyclopedia, vol. 1, p. 654, which is marked "Complainant's Exhibit, Chambers' Encyclopedia Extract;" Rees' Encyclopedia, American edition, vol. 3, article "Arundo," which is marked "Complainant's Exhibit, Rees' Encyclopedia Extract;" Ure's Dictionary, published at London in 1860, vol. 1, pp. 248 and 249, which is marked "Complainant's Exhibit, Ure's Dictionary Extract;" Dictionnaire Technologique, published at Paris in 1822, vol. 2, p. 512, and vol. 15, p. 255, which is marked "Complainant's Exhibit, Dictionnaire Technologique Extracts;" Engineers' and Mechanics' Encyclopedia, published at London in 1849, p. 139, which is marked "Complainant's Exhibit, Engineers' and Mechanics' Encyclopedia Extract;" Nicholson's Encyclopedia, American edition, published at Philadelphia in 1819, vol. 2, article "Bamboo," and vol. 9, article 2056 "Paper," which are marked "Complainant's Exhibits Nicholson's Encyclopedia Extracts;" Encyclopedia of Chemistry, published at Philadelphia in 1880, by J. B. Lippincott & Co., article entitled "Paper from Bamboo," on pages 533 and 534 of vol. 2, which is marked "Complainant's Exhibit Encyclopedia of Chemistry Extract;" Chemistry, Theoretical, Practical, etc., by Dr. Sheridan Muspratt, published at New York, by Virtue & Yoston, part of page 642, which is marked "Complainant's Exhibit Muspratt's Chemistry Extract." Defendant's counsel admits that the books referred to were published and circulated at the respective dates of publication above mentioned and that Muspratt's Chemistry was published and circulated prior to 1880.

It is agreed that the copies of said extracts may be used in evidence with the same force and effect as the original books, subject to the correction of any errors that may be found therein upon the production of the original books and the addition of any further extracts from the same article which defendant may desire to add.

Complainant's counsel also offers in evidence Patent Office copies of letters patent No. 41627, granted to Philip Lichtenstadt, February 16, 1864, which is marked "Complainant's Exhibit Lichtenstadt United States Patent;" No. 68863, granted to Charles Heaton, September 3, 1867, which is *which is* marked "Complainant's Exhibit Heaton United States Patent;" No. 70474, granted to Robert W. Russell and Thomas Howland, November 5, 1867, which is marked "Complainant's Exhibit Russell and Howland United States Patent;" No. 87295, granted to Louis S. Robbins and John A. Southmayd, February 23, 1869, which is marked
2057 "Complainant's Exhibit Robbins and Southmayd United States Patent."

Complainant's counsel also offers in evidence the bamboo tray and baskets produced by Dr. Morton and referred to in his answer to question 68, which are marked respectively, "Complainant's Exhibit Bamboo Basket No. 1," and "Bamboo Basket No. 2," and "Bamboo Tray."

Complainant's counsel also offers in evidence an article entitled "The New Electric Light," printed on pages 202 and 203 of the Telegraphic Journal and Electrical Review for May 15, 1874, published at London during the year 1874, and the same is marked "Complainant's Exhibit Telegraphic Journal Article."

Defendant's counsel consents that a copy of the said article may be used in place of the original book, subject to the correction of any errors that may be found therein.

Complainant's counsel admits that the book entitled "Eclairage a' L'Electricite', par Hippolyte Fontaine," and the book entitled "Electric Lighting, by Hippolyte Fontaine, translated by Paget Higgs," marked in evidence after answer to cross-question 225 of the deposition of Charles R. Cross, were printed, published and circulated on the dates shown by their title pages respectively, viz., 1877 and 1878.

75 Q. Do you, upon looking over your deposition, desire to make any explanation or correction of any part of it, and if so, please make such statement as you desire to make in this regard.

A. In looking over my deposition, I noticed a statement in answer 34 that, while correct in view of what I had in mind in making the answer, may not be correct in reference to other
2058 considerations which did not occur to me at that time. What I refer to is contained in the following words:

"On the other hand, if the material were hard carbon, then, on account of the brittleness of that substance, the strains produced by expansion might be likely to cause fracture in the arch form quite as much as, or more than, in the form of a straight pencil, because in the case of a straight pencil the expansion and contraction would force a yielding or movement on the part of the supports, and would be equally distributed throughout the conductor, whereas, when this conductor was in an arched form, the same strain would have more tendency to rupture the arch than it would to move the supports in the previous case."

When making this statement, I was regarding the problem as one of a straight column, or beam, under compressive strain, as compared with a bent column, or beam, under like strain, and, under such conditions, what I have stated would be correct; but if the actual problem is one in which, as compared with the column or beam, which in this case represents the conductor, the supports are substantially unyielding, and therefore the beam or column must change its form under the applied stress to a limited degree; in that case, I think that the arch form would be less liable to break than the straight bar, even though the material of which it were made were as rigid and brittle as the ordinary hard carbon, but, of course, the advantage secured by the arch form would be much less with a brittle material than with a more tough and flexible one. This last condition is that which I think would be controlling in the case of such lamps as we are now considering; and therefore, taking everything into consideration, I think that the arch form would have some advantage over the straight bar, even with a conductor made of hard carbon.

Adjourned till Tuesday, the 23d inst. at 10.30 a. m.

2059 TUESDAY, *April 23d*, 1889.

Met. Present, counsel as before, and the cross-examination of Prof. MORTON was commenced by Mr. DYER, as follows:

76 X Q. You have given a considerable importance by you- answer 6 and other answers to the use of the word textile in the patent in suit. Please state where you find that word used in the patent in suit and also in the original application.

A. In the patent in suit I find the word "textile" used in three places. In the first place, it occurs in the specification on line 23, page 2, in the following sentence:

"The advantages resulting from the manufacture of the carbon from vegetable fibrous or textile material instead of mineral or gas carbon are many."

In the next place, I find it in the first claim which reads:

"An incandescing conductor for an electric lamp of carbonized fibrous or textile material and of an arch or horseshoe shape, substantially as hereinbefore set forth."

And I also find this word near the end of the fourth claim where it occurs in the following context:

"Consisting of carbon made from a fibrous or textile material having the form of an arch or loop substantially as described, for the purpose specified."

In the application, I only find this word in the fourth claim which reads as follows:

"An incandescing arc made of carbonized fibrous or textile material."

77 X Q. Does the word occur at any other point than these you have mentioned either in the patent or the original application?

2060 A. It does not.

78 X Q. What specific material, if any, in your opinion is named in either the patent or original application to which the term "textile" could be properly applied?

A. Nothing more specific than the word "textile" itself, which under the circumstances is, I think, abundantly specific without further qualification, except so far as it is qualified by the terms "vegetable fibrous."

79 X Q. There is, then, no specific material mentioned which is properly textile material?

A. Not as I understand it.

80 X Q. Throughout your deposition, you have given the "intelligent artizan" the credit of quite an extensive knowledge, prior to 1880, of the art to which the patent in suit relates. What class of men had you in mind?

A. I do not think that I have credited my "intelligent artizan" with any more knowledge than would be possessed by any good workman who had been accustomed to the construction of philosophical apparatus, such as the electric light regulators for the arc light, who was familiar with the operation of such apparatus, and had informed himself as to the state of the art in connection with incandescent lighting by reading the more important patents and publications prior to 1880, which have been put in evidence in this case, and it is such a man as this that I have had in mind.

81 X Q. Where would he be instructed by the state of the art "that the carbon conductor must be of uniform structure and conducting power throughout its length," as stated by you in answer 6?

A. Among other sources of information on this subject, he would have the information derived from various patents and publications which refer to the importance of purity and uniformity in structure in the carbon rods or pencils used in electric lighting, as well as by such knowledge of general principles as he would naturally possess, which lead necessarily to the same conclusion.

2061 82 X Q. Where is the information or knowledge to be found?

A. In the ordinary text books on electricity, which give instruction as to the fact that the heat developed in a conductor varies with its resistance and the like.

83 X Q. I intended to refer more particularly to the "uniform structure" which you think the intelligent artizan would have been instructed by the state of the art to employ. Where would he have found this instruction?

A. In these very same books, as well as by his own observations in connection with the operation of arc lights, as these would teach him that variations in structure involved variations in resistance, and therefore irregularities in heating.

84 X Q. Where would he find the instruction or information which would lead him to bend the fibrous material into the arch shape before carbonization, rather than produce that shape by cutting?

A. From the utter impossibility of obtaining this form in any other way when he was operating with the ordinary textile material, and from the exercise of ordinary intelligence when he was operating with vegetable fibrous material less definitely textile or quite removed from the class of textile materials as generally understood.

85 X Q. Then you consider that the reference to textile material, in the patent in suit, would be of importance in controlling the artizan as to the method of cutting vegetable fibrous materials generally?

A. It would be, because it would start him of necessity on the right track and render it impossible for him to go wrong.

86 X Q. Suppose he started with paper instead of a textile material. Properly speaking, what would the information conveyed by the state of the art lead him to do as to cutting?

A. It would make no difference what he started with as to what he would do or find himself instructed to do, provided he had read the entire patent, in which case having been not only instructed by the reference to textile material how to prepare 2062 his carbon loop, but in a sense absolutely restricted to a single method, he would naturally and as a matter of course without the necessity of any thought or reflection, have applied the same method to the paper material, if he elected to operate upon that first. If, however, he had not read the entire patent, but only that part referring to paper, then ordinary intelligence, requiring little or no aid from anything in the state of the art, would lead him to select a paper of fine material and uniform structure, and to cut the same into an arch shape before carbonizing it.

87 X Q. What is the single method to which he would be absolutely restricted in a sense?

A. Taking or selecting his material in the form of a thread or cord of uniform cross-section, and bending the same into an arched form before carbonizing it.

88 X Q. That is, as I understand you, the direction contained in the patent to use textile material, would so firmly impress the artisan that such a thing as thread was the proper material to start with, that he would in making the carbon from any of the vegetable fibrous material contemplated by the patent, first cut the straight strip of the material and bend it into the arch form before carbonization. Have I correctly stated your view?

A. You have, though I should add that the references to fibrous material would in certain cases confirm this suggestion, in other words, would lead him to bend rather than cut a material when bending would manifestly secure the continuity of its fibre which cutting would destroy.

89 X Q. Is it not a fact that the patent in suit shows the carbon as wider in a vertical direction than horizontally?

A. It is.

90 X Q. Would not the most natural way of constructing a carbon of the dimensions shown in the patent be to cut the material out in the shape of an arch rather than to bend the material in the direction of its greatest thickness?

2063 A. If these dimensions were to be exactly followed, and there were no controlling consideration, that is so. In other words, if this carbon were to be made out of paper, it would be natural under these conditions to cut it out in the arch form and not to bend it, because in the case of paper the continuity of the fibre would be equally preserved in either way, but if the material operated upon were a distinctly fibrous substance like bamboo, for example, then I think the expediency of preserving the fibre would lead any one to bend it and not cut it into the arch shape.

91 X Q. But you think that the direction to use a textile material would be more controlling as an indication of the method of shaping the conductor than the shape and size illustrated in the drawing of the patent in suit?

A. I think it would convey more instruction, or be a better guide, because it would apply generally to a great variety of conductors, whereas the figure in the patent would only illustrate a single one.

92 X Q. You have stated in answer 6 that Dr. Barker "points out very correctly that there are many kinds of paper and also of wood which would not answer for the construction of an incandescent electric lamp," but you think "that this would be equally manifest to an intelligent artisan:" where would the intelligent artisan find this matter made manifest by the state of the art?

A. By that part of the state of the art which informed him that the incandescent conductor for an electric lamp must be continuous and uniform in cross-section and in conducting power or resistance.

93 X Q. That is, if he understood the general electrical principle that the heat is due to the resistance and hence to have a uniform heat and light throughout the length of the incandescent conductor, there must be uniform resistance?

A. Yes, and in addition to this that imperfections in uniformity would lead to the rapid destruction of the conductor.

2064 94 X Q. And you think that the intelligence of the artisan could have been relied upon before 1880 to apply this general principle, so as to enable him without experiment to select from the vast realm of vegetable fibrous materials the proper ones for the successful manufacture of an incandescent conductor?

A. It would undoubtedly have enabled him to select a number which would have been efficient, but, of course, I do not mean that either then or now the intelligent artisan, or anybody else, could pick out with certainty all the materials that would operate successfully and reject only those which would not.

95 X Q. That is, as I understand you, he would probably select

materials all of which would not be operative and would discard the inoperative ones by experiment?

A. No, that is not at all my meaning. What I do mean is, that he would select a number which would be certainly operative, but would reject the great majority of vegetable fibres, among which there might be some which would be operative, if used.

96 X Q. He would know the condition of uniformity required for an incandescent conductor, and would know enough about the kind of carbon which would be produced by carbonizing the different vegetable fibrous materials, to enable him to select without experiment at least some vegetable fibrous materials which would give on carbonization what he would know without experiment to be a suitable conductor. Is that a correct statement of your views?

A. No, not at all. He would know that his carbonized conductor must have a substantial uniformity, and the patent would have informed him that he would find among fibrous vegetable or textile substances, materials which, when carbonized, would give him an efficient conductor. Without having any knowledge as to the kind of carbon which would be produced by carbonizing the different vegetable fibrous materials, he would feel assured that to produce 1065 a uniform conductor he must start with a uniform uncarbonized structure, made of vegetable fibrous material. This would lead him to select only the vegetable fibrous materials which were conspicuously fibrous and uniform, and so selecting, he would uniformly succeed without the necessity of rejecting anything by experiment, so long as he contented himself with the most promising substances, and did not venture into the field of uncertainty by operating with those possessing the indicated properties in an inferior degree.

97 X Q. How would he be able to select, unless he was acquainted with the uniform character of the carbon, which would result from the carbonization of the fibrous vegetable material?

A. His selection would not be guided directly by any knowledge as to the carbon produced, beyond the general knowledge that the structure of the carbon resembles the structure of the thing carbonized. He would, therefore, simply select fibrous materials which were uniform in their structure, and give them shapes uniform in cross-section and preserving the fibre uninjured as far as possible. Having done this, he would have complied with the directions of the patent, both expressed and implied, and could then look forward with confidence to a satisfactory result, not because he himself knew beforehand that such result must follow, but because the patent had instructed him that if he proceeded in this manner he would secure the desired result.

98 X Q. You have stated in answer 6, in substance, that defendant's experts assume that for a practicable incandescent lamp, an extremely fine or thin fibre is essential, but that you think that modern practice in electric lighting shows that a very fine fibre is by no means necessary or desirable. In support of this position you refer to certain low-resistance lamps, viz., the Edison "municipal lamps, lamps used in the Heissler system, and the complainant'

2066 Exhibit Thompson-Houston Lamp and Bernstein Lamp, all of which lamps you say are used in successive series. How long have low-resistance lamps of the character mentioned by you, been commercially manufactured and used, so far as you know.

A. I think that I saw some of these low-resistance lamps at the Franklin institute electrical exhibition about five years ago.

99 X Q. That was the beginning, as I understand you, of their commercial manufacture and use, as you recollect it?

A. As far as my personal knowledge and recollection goes, it was.

100 X Q. Complainant's Exhibit Defendant's Lamp is a high-resistance lamp, with a fine or delicate carbon, and is not a low-resistance lamp, such as those as are referred to in cross 98?

A. Yes, you are correct.

101 X Q. In answer to question 14 you state that the hydrocarbon treatment, you believe, is not universally used. What fact had you in mind in making that statement?

A. It has been stated to me that the Edison Company, in this country, did not use that treatment, although they employed it abroad, and I have also been informed that the United States Company only applied it to a portion of their lamps.

102 X. Is the hydrocarbon treatment referred to by you, the treatment described in the patent of Sawyer and Man No. 211,262?

A. It is substantially.

103 X Q. In answer to question 15 you have analyzed the original application of the patent in suit. Am I correct in assuming from that answer that, in your opinion, the word "arc" as used in the original specification and claims is descriptive of the shape of the incandescent conductor?

A. You are correct.

2067 104 X Q. Was it not the practice at the date of the application for the patent in suit, viz., Jan. 9, 1880, to copper-plate the carbon pencils or rods used in arc lighting; in other words, to cover the carbon with a coating of metal?

A. It was done frequently, but was by no means universal.

105 X Q. I understand you to have expressed the opinion that the powdered plumbago referred to in the original specification was probably intended simply to give the carbon an improved appearance by making its surface glossy, which you consider equivalent to blacking a cooking stove, and quite the same thing, because significantly plumbago is used as the polish in each case. How do you account for the fact that the specification speaks of using the powdered plumbago only in connection with carbonized paper?

A. Because, I presume, the patentees had as a matter of fact in making the experiments alluded to in this place, treated their paper carbons in this way, and not the other ones.

106 X Q. Don't you think that the wood carbon or charcoal conductors, as well as the conductors of ordinary gas carbon, would also need polishing?

A. They might have needed it, but might not have lent themselves so readily to its application, being possibly more frail or more brittle.

107 X Q. Do you think there would be any substantial reason why the wood or charcoal carbons and the gas carbons should not be polished, and would not their appearance be improved in the same manner by polishing?

A. I think it likely that there would be much danger of injury to the wood carbons in the effort to polish them, as they were probably of a delicate structure, and that, in the same way, the brittleness of the hard carbons might have rendered it dangerous to attempt polishing them. It is not unlikely that such polishing would have given a better appearance to all the carbons produced by these inventions at that time.

2068 108 X Q. Is it an ascertained fact that there would be any difference between paper carbon and wood carbon in respect to the ease with which they could be polished, if anybody desired to polish them?

A. No, it is only on my part a conjecture. The paper carbons would probably be flat and the wood carbons would probably be round in cross-section. This would render the polishing of the paper ones easier, as it seems to me.

109 X Q. Taking carbons of the size and shape shown in the drawing of the patent in suit, do you think there would be any material difference in respect to the ease with which the carbons could be polished in the manner you have indicated whether they were made from paper or from wood?

A. Not necessarily, but I think it likely that the carbon represented in the drawing is a paper carbon, and that if any one desired to make a carbon from wood, they would make it relatively longer and more slender and of a round section, in which case, as I have already indicated, it would be more difficult to polish it.

110 X Q. In the continuation of your answer 15 (on April 12, 1889), you state, in criticising Dr. Barker's answer to question 40, that Dr. Barker might be correct in his statement, that the mere mention of carbonized paper in the application, by itself, does not indicate that the inventors intended to employ a fibrous material shaped before carbonizing, or that a successful result would necessarily follow a process of construction founded on such meagre suggestion, but that you think the answer of Dr. Barker is based on incorrect assumptions. Why are Dr. Barker's assumptions incorrect, in your opinion?

A. Because they include, as I understand it, the assumption that the mere mention of carbonized paper, by itself and unsupported and explained by other statements in the application, is a proper subject for criticism or discussion in any effort to understand the meaning of this document or to find out what it reveals to the public in connection with the art to which it relates.

2069 111 X Q. What material fact did Dr. Barker omit in his assumption?

A. The material fact that the application states that the carbonized conductor is to be made of fibrous vegetable or textile material and to have an arch form.

112 X Q. Do you agree with Dr. Barker that the mere mention of carbonized paper in the application, by itself, does not indicate that the inventors intended to employ a fibrous material shaped before carbonizing, or that a successful result would necessarily follow a process of construction founded on such meagre suggestion?

A. To a certain extent. In other words, if this reference to carbonized paper was the only thing in the patent bearing upon the selection of material and the treatment of the same, we should certainly have an entirely different document from any now before us, and one in which it would probably be impossible to find all that you have stated in your question, although some of the items at least would be there, such as the indication that a structure formed substantially of the chemical compound cellulose, and peculiarly well adapted to shaping prior to carbonization, was one of the elements of the invention.

113 X Q. You have stated in answer to question 15, in criticising Prof. Brackett's answers 25 to 30 inclusive, that the earlier Sawyer and Man patent No. 205,144, describes a lamp structure or enclosing chamber which you find "to contain everything that is indicated in the patent in suit and to correspond accurately with the language of this final patent."

Is the lamp chamber described in the old patent 205,144, in terms as "made wholly of glass"?

A. It is not described in such words, but it is described as a structure to which such words might be appropriately applied.

114 X Q. You state in the same answer that the earlier patent 205,144 describes fully various methods of sealing in the electrodes. Where do you find that description?

2070 A. I find the following description:

"Through the stopper B are drilled two holes, Fig. 7, through which pass the bolts Q Q, protected or not by a cloth or paper lining. These bolts are tubes and their function is of the greatest importance. The bolt heads are accurately fitted to the upper surface of the stopper, and under them, coated with balsam or some cement, are thin paper or tin-foil washers *l, l*. The nuts *n, n*, are accurately fitted to the under surface of the stopper, and under them are similar washers *l, l*, similarly prepared. Thus arranged the bolts are permanently fixed to the base, and when the lamp is charged with the artificial atmosphere required, the binding posts *n, n*, whose set-screws are *o, o*, similarly guarded by washers *l, l*, are set up upon the bolts' ends, whereby the lamp is hermetically sealed."

It is to this that I had reference, these bolts being in fact the electrodes or conductors of the lamp.

115 X Q. Is that a description of more than one method of sealing?

A. It is, in so far as it suggests alternative arrangements as to the lining or the apertures, the use of paper or tin-foil washers and the employments of various cements.

116 X Q. Do you consider that these changes make any substantial difference in the method of sealing?

A. No substantial differences. They are all, as I understand, known equivalents of each other.

117 X Q. In your answer to question 17 you state that you consider "that the original application contains very clear and distinct instructions, leading, first of all, to the selection of material which would be of necessity already shaped prior to carbonizing." Am I correct in understanding that you refer to the instruction to use textile material?

A. You are correct.

2071 118 X Q. Am I correct in understanding that without that instruction it is your opinion that the original application would not with certainty lead "to the selection of material which would be of necessity already shaped prior to carbonizing?

A. It would not of necessity refer to a material shaped in all its dimensions before carbonization, but by its mention of paper, it would refer to a material which was of necessity shaped in one dimension, and which would so naturally suggest the propriety of shaping in the other dimensions before carbonizing, that I do not think any directions in that respect would be needed, since any intelligent artizan, in attempting to carry out the invention with paper, would, as a matter of course, so shape his conductor before carbonizing it.

Adjourned till Wednesday, the 24th inst., at 10½ a. m.

WEDNESDAY, *April 24th*, 1889.

Met; present, counsel as before, and the examination of Prof. MORTON was continued as follows:

119 X Q. In answer to cross 78, you refer to the qualification of the word "textile" by the terms "vegetable fibrous." Where do you find such qualification in the original application?

A. I find the qualification, in the first place, by the word "fibrous," used in connection with "textile" in the 4th claim, where it speaks of "carbonized fibrous or textile material." I find the suggestion that the textile material is limited to "vegetable," and does not include animal textile material, suggested by the fact that the only fibrous substances mentioned or alluded to in the patent are vegetable ones.

120 X Q. Is the term "vegetable" or "vegetable fibrous" found at any point by you, in the original application?

A. It is not.

2072 121 X Q. Are not animal materials conspicuous examples of what are ordinarily known as textile materials?

A. They are.

122 X Q. Are not animal materials also conspicuous examples of fibrous materials?

A. Some of them are.

123 X Q. Is not the mineral substance asbestos a fibrous ma-

terial, and would it not also be, properly speaking, a textile material?

A. It is unquestionably a fibrous material, though hardly what would be called in the ordinary sense, a textile material, being too brittle for any ordinary textile treatment, but aside from this, it is entirely excluded from consideration, because, as every one knows, a carbon conductor could not possibly be produced by heating it, nor could it be in any sense carbonized. This being a patent for an electric lamp having a carbon conductor, it is of course, unnecessary to consider in connection with it, substances incapable of producing such conductors.

124 X Q. Asbestos is made into paper as well as into an inferior kind of cloth or fabric, is it not?

A. It is, in a sense, as also is glass, which suggests another difficulty, that asbestos, being a non-conductor of electricity like glass, is manifestly ruled out as a material for producing incandescent carbon conductors.

125 X Q. Referring to your answer to cross 91, am I right in assuming that the drawing of the patent in suit, in your opinion, shows a conductor cut into the arch form rather than bent into that form?

A. That is my opinion; in other words, I think it shows a paper carbon which had been cut into an arch form and then carbonized.

126 X Q. If a carbon conductor of the shape and size of that shown in the drawing of the patent in suit were given its form after rather than before carbonization, that is to say, were made from a
block or mass of vegetable fibrous carbon or ordinary gas
2073 carbon, would it be cut into the arch form from the mass of
carbon, or would it be cut into a straight strip and bent into
that form?

A. From what I know of the properties of the various forms of carbon referred to in your question, I should say that a piece of carbon of such size and shape as is shown in the drawing, could not be produced by bending after carbonization, but must have been made by cutting and not by bending.

127 X Q. You have stated, with reference to the English patent of Greener & Staite No. 11076, of 1846, that the prisms or cylinders are designed for arc lights or arc incandescent lights. Have you fully considered the construction described, in which hollow cones of platinum are employed? Kindly do so, and state if you desire to modify that portion of your answer 20 referring to this patent.

A. I had considered this portion of the patent prior to making the answer referred to, but on looking at it further I should like to modify my statement by saying that I think the use of the prepared carbon cylinders referred to in this part of their patent might be consistent with their action either in the arc incandescent or true incandescent manner. If the ends of the prepared carbon cylinders were not conically shaped so as to fit the platinum cones, I think the action would be substantially arc incandescent; but if they were so shaped as to fit those cones, and thus secure a large surface of contact, then the operation might be of the purely incandescent sort.

128 X Q. You have stated, in connection with the Roberts English patent that it does not contain—

"The remotest suggestion as to the employment of a fibrous or textile material which might be shaped prior to carbonizing."

Do you consider shaping of the material prior to carbonizing essential to the production of the incandescent conductor which you consider covered by the patent in suit?

A. Not always. In other words, if the substance employed
2074 were paper, then the conductor of the patent in suit might be
shaped after carbonization, although, of course, this would be a very injudicious and unmechanical method of carrying out the process of construction indicated in the patent.

129 X Q. Why do you make a distinction between paper and wood carbon?

A. Because in the case of paper, the uniform and yet non-continuous arrangement of the fibres renders it easier to produce a conductor of uniform resistance by shaping into an arch form after carbonizing, whereas, in most cases, this would be impossible with wood carbon. I did not, however, intend to state that paper was the only substance in which shaping before carbonization might be dispensed with, but only to cite it as a conspicuous illustration.

130 X Q. What then did you mean by your statement quoted in cross 128.

A. I meant that while the patent in suit not only suggests, but substantially directs any one who is attempting to carry out the invention, to execute the same by shaping the material prior to carbonization, the Roberts patent gives no such suggestion. At the same time I do not consider that the claims of the patent in suit are so framed as to be limited to this particular method of preparing the carbon conductor, although it would be unquestionably the best as well as the most easy of application.

131 X Q. Then you do not consider it a material defect of the Roberts patent as an anticipating patent that it fails to suggest, in your opinion, a material which might be shaped prior to carbonizing?

A. Yes, I do. In other words, this suggestion or instruction is, I believe, of the utmost importance, because it enables one skilled in the art to so carry out the invention of the patent in suit as to secure success with certainty; but after he had availed himself of this instruction, and had so learned how to produce the desired re-
sult in this way, he might then find it possible in certain
2075 cases to secure a similar result by a variation from this order
of proceeding such as has been indicated.

Adjourned for lunch.

Resumed after lunch.

132 X Q. I understand your view to be that, although it might be possible to produce a practical incandescent conductor by shap-

ing after carbonization, yet it was necessary that the art should first be informed that such a conductor could be produced by shaping before carbonization, before the proper results could be ascertained to enable one to produce the conductor by shaping after carbonization, and that, while you do not wish to take the position that the claims of the patent in suit are limited to a conductor shaped before carbonization, yet you consider it an essential feature of the contribution to the art by the patent in suit that a proper conductor could be obtained by shaping the material before carbonization?

A. There are many points in the view you have stated with which I agree and some, such as the use of the word "essential," in which you do not quite express my views, and therefore I think I can best answer your question by stating exactly what I do think in reference to the subject indicated.

In the first place, it should be remembered that this is a patent for a product, in other words, for a thing made, and not for the process of making it. The thing made in this case is (confining ourselves at present to the particular part of the structure we have been talking about) a conductor for an incandescent electric lamp, consisting of a carbonized fibrous or textile material, having an arch form. Now, in order to produce this thing, the natural, easy and direct way, if we start with the material indicated in the patent and end with the product claimed therein, is to shape such
2076 material before carbonizing it, but at the same time, it is manifestly possible in some few cases that we might start with a material coming within the limits of the class indicated, and produce the product, having substantially the advantages which it would have possessed if made in the natural and easy way, by changing the order to the extent of carbonizing the fibrous material first and shaping it afterwards. Now when this method is followed, provided the conditions are such that the article produced has substantially the characteristics which would have distinguished it when made in the manner directly and naturally suggested by the statements of the patent, I should say that such product was the product set forth in this patent, and the production of which constituted the addition to the state of the art contributed by this patent.

133 X Q. Then all carbons from vegetable fibrous material would not be the conductor of the patent, but only those having certain characteristics; where do you find the characteristics pointed out in the patent in suit?

A. The characteristics which I consider must be possessed by a carbon conductor in order to make it the conductor of the patent in suit, are such as distinguish a conductor made in accordance with the indications of this patent, that is, made from vegetable fibrous material, shaped before carbonizing and having an arched form. It is therefore, as I understand, not necessary that they should be pointed out specifically in the patent in suit, since they will be manifest to any one who, following the direction of the patent, produces the product in question. It is a fact, however that some of the characteristics are pointed out in the patent in suit in the passage which begins with line 100 on page 1, and continuing to the end of line 13 on page 2; also beginning at line 21 of page 2, and continuing to the middle of line 30.

134 X Q. Where do you find, in the original application, any indication of shaping before carbonization?

2077 A. Chiefly in the 4th claim which reads, "an incandescing arc made of carbonized fibrous or textile material," although I find that the reference in the 3d claim to carbonized paper and the reference to carbonized paper covered with powdered plumbago in the specification, strongly suggest the same thing, because the textile material would be of necessity shaped prior to carbonization; the fibrous material would almost of necessity in the hands of an intelligent person, and the paper likewise almost as certainly.

135 X Q. Then you gather this instruction from the materials referred to in the original application, and not from any direct statement in that application. and in this connection, I understand you, you give special weight to the word "textile"?

A. That is so, from the materials, and from the statement that the conductor is to have an arch form?

136 X Q. The rest of the knowledge would be supplied by the "intelligent artisan" acquainted with the art prior to the invention of Sawyer and Man?

A. It would be.

137 X Q. You have referred to Dana's Mineralogy as defining lignite. Is not the following also found in Dana upon the same topic:

"The term brown coal is, however, applied generally to any coal more recent in origin than the era of the great coal beds of the world, although it may not have any distinct remains of a woody structure, or burn with an empyromatic odor. The name lignite has sometimes the same general application, though without strict propriety."

A. I find the quotation you state in an edition of a work entitled "Manual of Mineralogy, by James D. Dana, A. M.," published in New Haven, 1876. This appears so be a much smaller work than the one from which my quotation is taken, although they are published within a year of each other. There is, however, no substantial difference between the statement above quoted, and that 2078 in the larger edition before referred to by me. In my edition, the author states that the term "lignite," while often applied to brown coal, generally, is sometimes restricted to masses which still retain the form of the original wood. The statement is made in the edition just quoted, that the broader statement is without strict propriety. In both editions, however, all the matter comes under the general heading, "mineral coal."

138 X Q. In Braude and Cox's Dictionary of Science, Literature and Art, I find the following statement under the head Lignite:

"The varieties of brown coal which show distinct marks of having been formed of trunks of trees, are conveniently separated from the rest under the name of lignite. As distinguished from brown coal, the most remarkable lignites are those of the Rhine.

* * * * * * *

Lignite splits and tears, while brown coal of the best kinds falls to powder."

I also find in Johnson's Encyclopedia, under the head "Lignite," that—

"The name originally given to bituminized wood, lignite, is applied to woody tissue in which the process of bituminization has begun, however modern it may be. * * * Changed wood is called lignite."

Do you agree with these statements?

A. I do entirely, and find that they support my previously expressed opinion that lignite was a variety of coal, and a substance universally regarded as a mineral, notwithstanding the fact that with many other varieties of coal, and even the diamond, were universally believed to be of vegetable origin, and often contain traces of the vegetable structures from which they were formed.

139 X Q. Are you acquainted with the appearance of the various known lignites?

A. I am not. I have seen one or two specimens, but I have never given it any special study.

2079 140 X Q. Is it not a fact that the piece of lignite which I now show you is evidently woody tissue in which the process of bituminization is so modern that the material is substantially a vegetable and not a mineral?

A. The specimen you hand me has a wood-like appearance, just as many specimens of asbestos and other fibrous minerals, but I notice that its fibrous structure has been pretty thoroughly destroyed, except in appearance, and that if a fragment is broken off, it is readily crushed to powder between the fingers. I think a mineralogist would say that it was a mineral, simulating, but not possessing, a vegetable structure.

The specimen of lignite referred to is offered in evidence by defendant's counsel, and the same is marked, "Defendant's Exhibit, Specimen of Lignite, April 24, 1889."

141 X Q. You have expressed the opinion, in answer 49, that the lamp of the patent in suit, "would last for 100 or 200 hours." Is that opinion based to any extent upon differences in the lamp structure, compared with those which existed in the earlier lamps?

A. Partly on that, and partly by information which has come to me in vsrious ways from others.

142 X Q. Then it is your opinion that the lamp structure of the patent in suit is an apparatus differing in important particulars from the lamp structures of the lamps which existed before the invention of Sawyer and Man?

A. It is.

143 X Q. You have referred to a statement in Fountaine's work on Electric Lighting to the effect that in a certain commercial use of the Konn lamp, the carbons, with the exception of the first, lasted about two hours. Did that statement refer to the life of all the carbons in each lamp or only to the life of each of several carbons?

A. It referred to each of four, that is each of these that were left after one of the four had been burnt almost at once.

2080 144 X Q. What then was the total burning time of such a lamp according to Fontaine's book?

A. Eight hours.

145 X Q. I hand you the American Gas Light Journal for 1879, vol. 30, and call your attention to a paper entitled "Lecture upon the electric light," delivered Oct. 17, 1878, before the American Gas Light Association by Prof. Henry Morton, Ph. D., pres. Stevens institute, Hoboken, N. J., beginning at page 2 and continued at pages 27, 51, and 74. Are you the author of that paper?

A. I am.

146 X Q. Was it delivered by you on the date stated in the introduction to the paper, and was it published in the American Gas Light Journal continuing through the numbers dated, Jan. 2, 1879, Jan. 16, 1879, Feb. 3, 1879, and Feb. 17, 1879, as appears by the volume handed you?

A. A lecture on that general subject was delivered by me on the date stated, and prepared the matter published in this journal subsequently and such matter was published at the various dates referred to. There was however, a great deal published in addition to what was actually said at the lecture, since I was desired by the editors of the joarnal to make this report as complete a discussion of the subject as I could.

The article referred to is offered in evidence and the same is marked Defendant's Exhibit Morton's Paper on the Electric Light, April 24, 1889.

It is stipulated by counsel for complainant, that a copy may be marked in evidence in place of the journal itself, subject to correction, with the same force and effect as if the journal itself were marked in evidence.

147 X Q. In respect to your qualifications as an expert, as expressed in your answer to the 2d question, have you not also had much experience as an expert in litigated cases, especially those relating to patents?

2081 A. I have.

148 X Q. When did you begin, and about what has been the amount of your occupation in this way?

A. The first case that I was called upon to act in was on the subject of canvas and rubber hose, about 17 years ago, since which time I have been called upon in a number of cases each year, probably by this time aggregating more than a hundred.

149 X Q. Did you testify as expert for the defendants in the case of Holliday and others *vs.* Pickhardt and others, in the southern district of New York, and reported in the 29th volume of the Federal Reporter, beginning at page 853?

A. I did.

150 X Q. Are you the Prof. Morton referred to in the opinion of

Blatchford, C. J., in the same case, published at page 147 of vol. 12 of the Federal Reporter?

A. I am.

Adjourned till Thursday, the 25th inst., at 2.30 p. m.

New York, *April* 25, 1889.

Met pursuant to adjournment.

Present: Mr. Curtis, for complainant, and Mr. Donnelly for defendant; and the cross-examination of Dr. Morton was continued as follows:

—. Do you remember the fact that on or about the 22d of December, 1879, you wrote a letter which was addressed to the editor of the Sanitary Engineer, and which was published in that paper about that date, in which, among other things, you disparaged certain statements which had previously thereto been published in the New York Herald concerning Mr. Edison, and also in your letter spoke in high praise of Mr. Edison's ability and of the work he was doing as an inventor in electric lighting?

2082 A. I have a general recollection that, at the request of the editor, I wrote him a letter about electric lighting matters at the time indicated, but I cannot say that I have now any clear recollection as to the contents of said letter. I have no doubt, however, that I spoke well of Mr. Edison because I have always thought well of him, and my personal relations with him have always been agreeable.

151 Q. Have you a copy of that letter in your possession, either here or at home, as published, and if so, will you please furnish the examiner with a copy of the same, so that it may be filed in evidence in this case?

A. I have such a copy at home, and will furnish it with pleasure.

152 Q. Do you remember of writing a letter to the New York Tribune, which was published in that paper Nov. 25, 1880, in which you spoke of the comparative merits of the Maxim and Edison incandescent lamp?

A. There was an interview published at that time. I cannot say that I now recall its substance, but have no doubt of its publication, and if I have a copy of it I will be glad to furnish it to the examiner.

Complainant's counsel consents that copies of the letter and interview above referred to as being published in the Sanitary Engineer and the New York Tribune may be furnished by Prof. Morton and filed in evidence, and used with the same force and effect as originals.

The same, having been furnished by Prof. Morton, are filed in evidence and marked Defendant's — Sanitary Engineer Letter and Interview, April 24, 1889.

Defendant also offers in evidence Morton Interview, N. Y. Tribune, Nov. 25, 1880, April 24, 1889, W. T. F., S. E.

2083 THURSDAY, *April* 26, 1889.

Met. Present, counsel as before, and the examination of Prof. MORTON was continued as follows:

Redirect:

153 R. D. Q. Referring to the opinion of the court on motion for preliminary injunction in the case of Holliday *v.* Pickhardt, 12 Fed. Rep., p. 147, which has been put in evidence by defendant—were the Exhibits A and B, therein referred to, substantially identical as matter of fact?

A. They were.

154 R. D. Q. What was Exhibit A and what was Exhibit B?

A. Exhibit A was a portion of the ordinary commercial acid magenta, manufactured in Germany by Cairo under his patent, and sold by Pickhardt & Kutroff, the defendants in the suit. Exhibit B, as a matter of fact, was also a portion of commercial acid magenta probably manufactured by Reed, Holliday & Co., in England, and sold by their representatives in this country.

155 R. D. Q. Did the fact of what B actually was, appear when the proofs were taken for final hearing?

A. It did. An analysis of that material showed that it contained 7.37 per cent. of chlorine, the commercial product sold by the agent of Reed, Holliday & Sons, which I examined, showing 7.63 per cent. of chlorine, the other constituents being substantially identical in the two substances. It also appeared, from the testimony of Prof. Seeley taken for final hearing, that in the process used by him for the preparation of the material which he introduced as this Exhibit B, he used no chlorine, and that no chlorine could have existed in the product of the process used by him. Prof. Seeley also in his testimony in the same connection, admitted that the material put in by him in connection with his affidavit above referred to might have been the commercial acid magenta of Reed, Holliday & Sons.

2084 156 R. D. Q. And upon the issues in that case, which were decided by Judge Wallace on final hearing in favor of the complainant and against the views of yourself, Prof. Chandler and others, was there a very large amount of testimony taken on both sides, and did much of it relate to difficult questions of chemistry?

A. There was an immense amount of testimony taken, much of which was of a highly recondite, chemical character.

157 R. D. Q. Is the accounting under the interlocutory decree in that case still proceeding?

A. It is.

HENRY MORTON.

Subscribed and sworn to before me this 26th day of April, 1889.

WM. T. FARNHAM,
Special Examiner and Notary Public.

2085 NEW YORK, *April 18th*, 1889.

Met pursuant to adjournment.

Present: Mr. Thomas B. Kerr, of counsel for complainant, and Mr. Walter K. Griffin, of counsel for defendant.

Testimony of Oliver B. Shallenberger.

OLIVER B. SHALLENBERGER, a witness on part of the complainant, being duly sworn, testifies as follows in answer to interrogatories by Mr. KERR:

1 Q. State your name, age, residence and occupation.

A. Oliver B. Shallenberger, age 29 years, Rochester, Penna.; electrician.

2 Q. What has been your electrical experience?

A. I commenced the study of electricity in 1880 with particular reference to its practical applications, my first work being in connection with the construction of incandescent lamps. I made experiments during the winter of 1880 and 1881 with a view to carrying out the instructions contained in the Maxim specification for an incandescent lamp issued about that time, and gained some experience in carbonization of paper and the requirements of the carbon for incandescent lamps. I continued the study of electricity at intervals until the latter part of 1884, at which time I connected myself with the Union Switch and Signal Company of Pittsburgh, and subsequently with the Westinghouse Electric Company as chief electrician, and have had during the five years since that time general supervision of the electrical work carried on by the company. A large amount of my time has been devoted to the study of incandescent lamps being immediately connected with their production on a commercial scale, averaging several thousand lamps a day for a portion of the time. During the last year and a half I have been associated in experimental lamp work with Mr. Alexander de Lodyguine of St. Petersburg, and have obtained much useful information through him. We have jointly carried on an extensive series of experiments with the object of perfecting, as far as possible, the incandescent lamp of the Westinghouse Electric Co., involving careful comparative tests of 2086 lamps of various types. I have recently carried out a series of experiments, assisted by Mr. Frank S. Smith and others, for the purpose of determining the practical usefulness of the Sawyer and Man lamp when constructed according to the directions furnished in the specification of the patent in suit. I have also investigated the general subject of the carbonization of fibrous materials, particularly of vegetable origin, and have carefully observed the fitness of carbons so obtained for use in incandescent lighting.

3 Q. Please state whether you had any other directions for the experiments referred to in your last answer than those furnished by the patent in suit.

A. My information was entirely derived from the specifications of the patent in suit, and from prior patents granted to Sawyer and Man to which reference is made in the patent in suit.

4 Q. Will you please produce samples of the lamps made by you in accordance with the patent in suit and describe the same, both as to construction and any tests or uses you made of them, fully and in detail; and also any other lamps of the same character made by you in addition to those which you produce in evidence?

A. I here produce six lamps, five of which are mechanically constructed in exact accordance with the drawings and description in the patent. The five lamps are marked "Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 1 Paper Carbon," together with the Exhibits Nos. 2, 3, 4 and 5 and are constructed mechanically as nearly like the patent in suit as possible. The carbon is supported by two carbon clamps, except in lamp No. 2, in which the clamps are of platinum; these clamps are supported on a disc as shown in the drawings, and insulated from each other; the supports for the clamp extend through the disc, and are electrically connected to copper conductors of corrugated form, which extend to the base of the lamp. The latter consists of a plate of glass having two openings about 2087 a quarter of an inch in diameter through which the tubular bolts pass. These bolts are constructed as shown in figure 5, of the patent in suit, which is as follows: A tube about three-eighths of an inch in diameter is turned off at one end to a diameter sufficient to allow it to pass through the holes in the plate leaving a flat flange to bear against the lower surfaces of the plate, the smaller end of the tube which projects inside of the lamp is threaded for attachment to the ends of the corrugated conductor. The thicker end which projects outside of the lamp is provided with an air-tight valve by means of which the opening in the tube may be closed. A cap is provided to screw over the projecting end of the tube when the lamp is finished. The glass plate is ground to fit accurately against the flanges of the tube bolts, so that without cement of any kind the joint is practically air-tight. These tube bolts serve the double purpose of ducts through which the air may be exhausted, or nitrogen admitted, and of conductors for supplying current to the carbon. Surrounding the carbon and conductors leading to it, and reaching down to the base plate is a tubular glass bulb provided with a flange at its lower extremity of the same external diameter as the base plate, this flange is ground perfectly flat, as is also the surface of the base plate, so that when the two are placed together they will form a practically air-tight joint in the same way as the tube bolts. Two brass flanges are placed above and below the joint between the base plate and the flange of the bulb, and these are drawn together by iron screws, the pressure being softened by paper washers placed between the metal and the glass. The joints are made air-tight and permanent by a thin coating of fir balsam applied previously to the assembling of the parts, and the base is protected by a brass cap of substantially the form shown in the drawing. The lamp marked "Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 6," is constructed in substantial accord with the specification of the patent in suit, but is

modified in the details of the base; instead of the base plate
2088 as shown in the drawing, a bottle stopper is used which is ground to fit accurately on the internal surface of the mouth of the globe. Through this stopper two holes pass for the admission of the tube bolts. The latter are of the same construction as previously described, except that instead of being formed of one piece they are composed of a platinum tube to which the thicker flanged portion is attached, the object of employing the platinum is to obtain nearly the same expansion in the tube as in the stopper and so maintain a tight joint. The clamps in which the carbon conductor is held in this lamp are of platinum; in other respects than those mentioned, it is constructed like the drawing figure 5, of the patent in suit. Each of these lamps was submitted to a test and the following records show briefly the result.

Lamp No. 1. Carbonized paper cut into arched form after carbonizing, tempered by heating in very attenuated hydrocarbon gas, bulb contains an atmosphere of nitrogen tested for one hundred and thirty-two hours and fifty minutes at proper incandescence, and is still in good condition as may be judged by the appearance of the carbon and absence of blackening in the interior of the globe.

Lamp No. 2. Paper carbon with platinum clamp. Globe exhausted to highest attainable vacuum. Tested for one hundred and thirty-one hours and twenty minutes. Carbon now in good condition, no blackening of the bulb, vacuum at the end of test good.

Lamp No. 3. Willow carbon. Atmosphere of nitrogen. Run at about sixteen candles for one hundred and fifty-six hours and three minutes. Is now in as perfect condition apparently as when started; no blackening of bulb; carbon perfectly bright and clean.

Lamp No. 4. Silk carbon vacuum lamp. Run for two hundred hours. No visible change in the appearance of the carbon. No blackening of the bulb. Exhausted April 2d. Vacuum tested April 17th and showed remarkably high exhaustion.

2089 Lamp No. 5. Silk-thread carbon. Nitrogen atmosphere. Burned for one hundred and thirty-eight hours and is still in perfect condition. Charged with nitrogen April 5th. Tested April 17th, at which time it showed evidence of perfect nitrogen atmosphere of low pressure.

Lamp No. 6. Bottle-stopper lamp. Carbon of piazava, platinum clamps. Exhausted to high vacuum. Thirty candle power. Was run for twenty-four hours and twenty minutes at about twenty candles and is now in perfect condition, both as to vacuum and condition of carbon.

In addition to these lamps I have tested the following which are not offered in evidence:

Lamp No. 7. Paper carbon; charged with nitrogen April 4th; ran forty-three hours and fifty-two minutes at fifteen candle power; broke at the clamp from imperfect contact.

Lamp No. 8. Nitrogen atmosphere at low pressure. Paper carbon; ran thirty-eight hours and forty-five minutes; broke from defective carbon.

Lamp No. 9. Paper carbon, nitrogen atmosphere; ran forty-seven hours and fourteen minutes. This lamp was charged with nitrogen at about half an inch pressure on March 28, and when tested April 17th showed the atmosphere to have remained constant as nearly as could be ascertained. This lamp was run at twenty candle power which required a high temperature with consequently short life.

Lamp No. 10. Paper carbon *in vacuo*; ran forty-two hours and thirty minutes at about sixteen candle power; accidentally forced to about one hundred candle power which probably was the cause of its short life. Was exhausted on April 2d, and showed very high vacuum when tested on April 17th.

In addition to these lamps several others were made or partly
finished and were not successful for various reasons. Two lamps
were forced so high as to break the globes, several were
2090 cracked at the flange or base plate and work was discontinued
on them for that reason. It was considered easier to make
up new parts than to hunt out the mechanical defects in the old
ones.

Adjourned to meet April 19th, 1889, at 10.30 a. m.

APRIL 19, 1889—10.30 a. m.

Met pursuant to adjournment. Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant, and the examination of the witness OLIVER B. SHALLENBERGER is continued:

5 Q. Please state fully and in detail the operations of carbonizing the carbon conductors, and of filling the lamps, or exhausting the same, referred to in your answer to question 4.

A. The material of which the carbon conductors were made was usually paper and that chiefly employed was a sort of bristol-board having a thickness of about .013″ and blotting paper about .03″ in thickness, the latter was sometimes pressed and was soaked in a solution of sugar before carbonizing. The blanks for carbonizing were punched out in the form of rings or horseshoes from $\frac{1}{8}$ to $\frac{1}{16}$ inches in width and with a radius of about $\frac{3}{8}$ of an inch. These blanks were placed in paper boxes surrounded by powdered carbon and placed in graphite crucibles the whole being filled also with the powdered carbon. A cover was then placed on the crucible and roughly cemented in place. This crucible was then heated in a gas furnace for six or eight hours and allowed to cool before removing the carbon.

Carbons were also made of willow which was cut into thin slips
.05″ square, which were bent into horseshoe form after soaking in
hot water over the end of a carbon block. They were then allowed
to dry and packed in powdered carbon for carbonization as
2091 described with reference to the paper carbon. One carbon
was prepared by cutting out from a piece of carbonized paper a
horseshoe strip about an eighth of an inch wide. The carbon in lamp
Exhibit 6 was made from a grass called piazava, a piece of which

was bent around the end of a carbon block to give the required form and was carbonized while on the block and surrounded by powdered carbon.

Carbons of silk, such as are used in the Westinghouse Electric Company's ordinary lamps were also employed, such carbons being taken from stock and treated as is usually done in the preparation of those carbons. The latter carbons were used for the purpose of comparing the condition of carbons whose characteristics are well known when used in the Sawyer-Man lamp of the form shown in the patent in suit, with that exhibited in lamps of modern form.

All of the carbons, so far as I recollect, were tempered and lightly treated in an attenuated atmosphere of hydrocarbon gas, for the purpose of consolidating the fibres, filling the pores and rendering uniform the resistance throughout the length. This process was carried out as described in the patent No. 211,262 of Sawyer and Man granted prior to the issuing of the patent in suit. The amount of deposited carbon was in most cases barely sufficient to brighten the surface and did not cause any perceptible thickening when measured by a thousandth *guage*. A noticeable decrease of resistance was produced, however, by this process owing to absorption of the gas within the pores of the carbon without increasing the external dimensions. The tempering and treating process is substantially as follows: The carbon to be treated was mounted on two electrodes having suitable clamps attached to their extremities, and supported on a horizontal plate to which communicated tubes leading to the exhaust pump, gas reservoir, and mercury *guage*. A bell glass was placed over the carbon thus mounted resting at the bottom on a rubber ring so as to make an air-tight joint. Communication was then established with the air pump until the mercury gauge showed the highest exhaustion attainable when
2092 hydrocarbon gas was admitted, and allowed to flow in sufficient quantity to lower the pressure about one-half or three-quarters of an inch. The atmosphere in which the treatment was carried on was therefore highly attenuated, and contained very little gas as compared to the amount contained in the same space at atmospheric pressure. The object of this arrangement was to enable the operator to reduce the treatment to as small an amount as was thought desirable, and consistent with the proper consolidation and rendering uniform the resistance.

In order to determine the effect of the presence of a small amount of hydrocarbon gas within the receiver, several carbons were treated, or tempered, in an atmosphere of nitrogen. The result being a very decided consolidation and solidifying of the fibres so that the texture became much more firm and the carbon more readily handled. It was evident, therefore, that the tempering process and treating are simply merged into each other by the heating of the carbon in an atmosphere of hydrocarbon gas, and that the disposition of carbon occurs very largely within the pores of the fibrous material. The relative amount of internal and external deposit is regulated very readily by varying the pressure of gas in which the process is carried on, a large amount of gas and considerable pressure producing a thicker external coating with less absorption of gas within the fibres. By reducing the pressure to about one-half inch the internal treatment or absorption of gas within the pores may be carried on to such an extent as to diminish the resistance of the carbon to one-half of its original reristance in the case of most fibrous materials, and in the case of blotting paper can be reduced to one-tenth of the original resistance. The physical condition of blotting paper is very noticeably changed during this process so that instead of being soft and easily pulled apart, as it is before treatment, it becomes tough, elastic and metallic in its properties, without any change in external dimensions. Nothing better 2093 illustrates the wonderful adaptability of the fibrous structure for the purpose of producing lamp carbons that this property of absorbing and decomposing hydrocarbon gas, so as to render the quality of the material exactly such as is most desirable for the purpose.

In marked contrast to the foregoing an experiment was made to determine the effect of heating a piece of Carré carbon in exactly the same way and in the same gas in which the treatment of the fibrous carbons was carried out. A piece of carbon pencil two inches long and .0185″ in diameter was placed on the treating clamps and subjected to the passage of a current sufficient to heat it to a brilliant white heat for one minute. The resistance before this process was 17 ohms, and a measurement immediately afterward showed a resistance of 17.5 ohms, the diameter remaining the same. The two resistances were considered as substantially agreeing inasmuch as the lengths measured were not very accurately taken, possibly. It may be as well to add by way of explanation, that Carré carbons are made by a process similar to that used in the manufacture of arc-light carbon, that is, by mixing powdered carbon with some suitable viscous carbonaceous material, such as coal tar, then forming into cylinders or pencils, and baking at a high temperature. The result is an amorphous mass of hard carbon having no fibrous structure, quite brittle and therefore incapable of bending into a new form after being manufactured. It was found that the treating process when applied to such a pencil of carbon, although a slight change in the appearance of the surface was produced, did not change in any way the internal condition. The pencil remained as brittle as before, and as shown by the foregoing figures, was not changed in resistance. A piece of fibrous carbon produced from a siip of piazava one and seven-eighths inches long, and of an average diameter of .3″ had a resistance before treating, of 40 ohms, and after being heated for one minute in gas of the highest attainable attenuation was reduced to 30 ohms without perceptible increase in diameter.

A semicircular carbon of blotting paper .021″ in thick- 2094 ness and .055″ in width before treating, had a resistance of 143 ohms. After treatment for three minutes in attenuated gas, the dimensions were .021″ thickness and .053″ in width, and the resistance was reduced to 3 ohms, or only one-eleventh of the untreated resistance, and with certainly no increase in cross-section.

This illustrates in a marked degree the adaptability of a fibrous carbon to the treating process, and it is my opinion that without the treating process, the availability of carbon as a material for the conductors in incandescent lamps is certainly very limited.

The exhaustion of the lamps was effected by attaching lead tube to the bottom of the tube bolts which passed through the base of the lamp, and connecting by a rubber tube to the mercury pumps. The lamp was then exhausted in the ordinary way, and occluded gases were driven off by passing the current through the carbon, then the valves were closed and the tubes removed and the caps screwed in place. The exhaustion was tested by observing the character of the discharge through the bulb when placed between the poles of an induction coil of high electro-motive force. There was nothing unusual about this part of the process of making the lamps.

Such lamps as were filled with nitrogen were manipulated substantially as described in the Sawyer and Man patent No. 205,144. The nitrogen was prepared and purified over melted sodium according to the directions found in Stillman's patent 225,730. In general this process is as follows: The nitrogen is generated by heating a solution containing am-onium chloride and potassium nitrite. The resulting gas is passed through Wolff's bottles containing pyrogallate of potassium, caustic potash solution, ferrous sulphate and sulphuric acid. The gas thus generated and purified is collected in suitable rubber bags, and when used for filling lamps is again purified to render it as free from all contamination with other gases as possible. The order in which these reagents were used in my process of filling the lamp was as follows: Ferrous sulphate
2095 pyrogallate of potash, caustic potash solution, sulphuric acid,
dry caustic potash, dry phosphoric anhydride, and finally melted sodium. The melted sodium removes the last traces of oxygen and acts as a convenient indication of the purity of the gas by remaining untarnished when the proper degree of purity is reached.

The lamp to be filled with nitrogen was connected by lead pipes to rubber tubes attached as before described, and the gas was passed through until a proper degree of purity was reached. Before introducing the first nitrogen the air was withdrawn by attachment to a mechanical pump to facilitate the process and prevent the admixture of air with the nitrogen. In some cases the lamp was previously exhausted on a mercury pump.

Counsel for complainant offers in evidence the lamps referred to by the witness in answer to question 4 as those produced by him as follows, to wit:

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 1, Paper Carbon. W. T. F., S. E."

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 2, Paper Carbon, W. T. F., S. E."

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 3, Willow Carbon, W. T. F., S. E."

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 4, Silk Carbon, W. T. F., S. E."

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 5, Silk Thread Carbon, W. T. F., S. E."

"Complainant's Exhibit Pittsburgh Sawyer-Man Lamp No. 6, Piazava Carbon, W. T. F., S. E."

6 Q. Please state whether you know of any other fibrous material suitable for making the illuminating conductors of incandescent lamps, and, if so, please name them.

A. There are a number of woods suitable, in my opinion, for carbonizing for the purpose of forming a conductor for incandescent lamps, such as ash, hickory, linwood, linden, birch, poplar, willow tree, yew, elm, tulip, and other woods having suitable 2096 straight fibres, or fibres which may be easily split without too much cutting across from one fibre to the other. There are a great many suitable grasses, such as ixtl or Mexican grass, piazava, manilla, flax, hemp, dog's grass, etc., and such fibrous growth as the stem of the palm-tree branch, or large leaf, rattan, broom-corn, bamboo, palmetto, and such textile materials as cotton thread, linen thread, linen twine, silk thread, jute, and the like. This list could be indefinitely extended.

7 Q. Please state whether you have made any incandescent lamps containing illuminating conductors made of any of these materials, and if so, produce specimens of such lamps, and state whether you made any tests of the same, and if so, describe such tests.

A. I have recently prepared and tested lamps with carbons made from the following materials:

1, ash; 2, hickory; 3, linwood; 4, broom-corn; 5, piazava; 6, palmetto; 7, rattan; 8, ixtl fibre; 9, manilla fibre; 10, hemp cord; 11, linen thread; 12, bamboo paper.

Owing to the limited time available for the preparation of these lamps it has been impossible to give all of them exhaustive life tests, but such of them as have been tested for a considerable time have given extremely satisfactory results. Lamp No. 4, in which the carbon is of broom-corn, was tested for seventy-eight hours, fifteen minutes at ten candle power, and shows no perceptible deterioration. Lamp No. 1, which has an ash carbon, was tested for the same length of time, and is in equally good condition. Lamp No. 2, in which the carbon is of hickory, was run at 16 candle power, as was also the ash carbon, and for the same length of time. This carbon, although not as bright throughout its length as the two previously mentioned ones, is still in excellent condition; neither of these three lamps shows any sign of blackening on the interior of the bulb. No. 3, which contains a linwood carbon, is very similar to the ash carbon in all its characteristics, both carbons being quite uniform in resistance before treatment, and 2097 showing much the same behavior during the treating process.

The carbon in lamp No. 7 is of rattan, and remains in good condition after a test of 21 hours and 35 minutes. This fibre is easily prepared and formed into shape before carbonization, and is of uniform resistance before treatment. No. 5 was tested 23 hours and 15 minutes, and is still in good condition. No. 10 has a carbon made from a piece of ordinary hemp twine, and is in perfect condition after running 23 hours and 15 minutes. All of the carbons mentioned were particularly adapted for moderately low e-ctromotive force, and in the lamps actually made, ranged from about 20 to 50 volts. Lamp No. 12 contains a carbon of bamboo paper, specimens of which were obtained by Mr. Broadnax, and were given to me for the purpose of testing for carbonization. It is undoubtedly well suited as a material for making incandescent carbon. The manilla, ixtl and palmetto fibres are particularly well adapted for lamps of low candle power or high electro-motive force. Lamp No. 11 was tested for 24 hours at 16 candle power, 109 volts, and is in good condition. No. 9 was tested at 10 candle power, 83 volts, and is evidently a very suitable material for high-resistance filament. No. 8, in which the carbon is of ixtl, gives 16 candle power at 80 volts, and is, perhaps, the best material in the above list, so far as I have determined for a high-resistance filament of low candle power. No. 6 contains a palmetto carbon giving 5 candle power at 31 volts, this would be equivalent to 16 candle power at about 95 volts if the fibre were made proportionately long. A test of 23 hours developed no defects. In all of these lamps the treating was so slight as to cause no perceptible thickening of the carbons, being barely sufficient to consolidate the fibres and render the resistance uniform throughout.

The selection of these materials was made without any previous tests and all of the material selected and considered suitable for carbon were practically successful; several of them were suggested by Mr. Alexander de Lodyguine as having been used successfully
by him in the manufacture of lamps commercially, the others
2098 were tried simply because a knowledge of their characteristics
made it seem probable that they would make good carbon.
I have no doubt that many others equally suitable could be easily found by any one by the exercise of a fair amount of judgment.

Counsel for complainant offers in evidence the lamps mentioned in the last answer as follows:

Complainant's Exhibit Ash Lamp, W. T. F., S. E.
Complainant's Exhibit Hickory Lamp, W. T. F., S. E.
Complainant's Exhibit Linwood Lamp, W. T. F., S. E.
Complainant's Exhibit Broom-corn Lamp, W. T. F., S. E.
Complainant's Exhibit Piazava Lamp, W. T. F., S. E.
Complainant's Exhibit Palmetto Lamp, W. T. F., S. E.
Complainant's Exhibit Rattan Lamp, W. T. F., S. E.
Complainant's Exhibit Ixtli Lamp, W. T. F., S. E.
Complainant's Exhibit Manilla Fibre Lamp, W. T. F., S. E.
Complainant's Exhibit Hemp-cord Lamp, W. T. F., S. E.
Complainant's Exhibit Linen-thread Lamp, W. T. F., S. E.
Complainant's Exhibit Bamboo-paper Lamp, W. T. F., S. E.

8 Q. From your experience in the manufacture of lamps in accordance with the patent in suit, what is your opinion of the ability to make good practical lamps of that construction, either with an atmosphere of nitrogen gas, or with a vacuum?

2099 A. The result of my work in the making of these lamps has been to demonstrate beyond any doubt the entire practicability of such a lamp structure. The matter that at first was considered of the greatest difficulty in beginning the work, namely, the preservation of an air-tight joint at the base of the lamp, proved to be one which was easily overcome by the exercise of ordinary care and good workmanship in the preparation of the parts, and by proper attention in the assembling of those parts. It was found that each lamp could be made tight enough in the factory to be practically tight when the parts were simply put together dry, relying only on the intimate contact of the flat surfaces for the joint. On several occasions I so placed the parts together, and partially exhausted the lamp when it was found that a sufficient exhaustion was maintained within the lamp in this way to firmly hold the base plate in place for an hour or so, in fact, this method was used frequently during our work to test the accuracy of the workmanship on the lamps as they came from the factory. It is quite evident when the matter is looked into with a little care that there is no serious difficulty in this part of the work, the joints depend entirely upon the intimate contact of flat surfaces, not only between the flange at the bottom of the globe and the base plate, but also between the flanges of the tube bolts and the base plate. Nothing is easier in the line of mechanical work than to grind surfaces practically flat, assuming that suitable appliances are employed for the purpose. It is well known that two heavy metal blocks may be so accurately ground together that when placed in intimate contact with each other, the air is so perfectly excluded that it is possible to lift both blocks by picking up either one of them, the atmospheric pressure holding them together as one piece. It is entirely unnecessary to attain any such degree of perfection in the contact of the joints in an incandescent lamp, since the coating of balsam used on the surfaces fills up any minute irregularities, and the result is that when two surfaces are pressed together the air is excluded
2100 and a perfect joint is obtained. A sort of molecular adhesion comes into action in addition to the external pressure of the atmosphere, holding the surfaces together with great force, so that when once placed together it is nearly or quite impossible to remove one from the other by a direct pull.

The only other air-tight joints required are the small valves in the tube bolts, and these again are easily made tight by grinding in place in the ordinary way; such valves are so common as to require no explanation. The application of a small amount of balsam around the valves when they are finally closed is sufficient to insure their tightness.

All of the particulars referred to above, as will be seen, are simply matters of ordinary care in the putting together of the parts, and are such matters as any careful workman, as for instance, an instrument-maker, would attend to as the result of his experience. The operations are, however, so simple that they could be readily learned by any person of average intelligence in a short time.

It is in my opinion more difficult, if any difficulty is supposed to

exist in producing a tight joint, to produce a vacuum lamp than one filled with an inert gas, since the joints are then subjected to the severest possible test. As will be seen by referring to the record of the tests of these lamps as it has already appeared in my testimony, the exhaustion of such lamps as were run *in vacuo* did not deteriorate in the least, even in cases where the carbons burned out within forty or fifty hours, most of the failures were due either to defective carbon, or overrunning the lamp for the sake of producing a brilliant effect. It was not thought that there would be any difficulty in obtaining a sufficiently good carbon, or in fact, in employing such carbons as are now used in incandescent lamps, if the lamp could be made perfectly tight, such proved to be the case, and little time was spent on the production of any particular kind of paper carbon as it is a matter of common knowledge that paper carbons have been and still are used commercially with perfect suc-
2101 cess. A number of carbons were, however, prepared of various kinds of paper, including bond paper, cardboard and blotting paper. Most of the lamps prepared contained carbons of cardboard which was found to be easily prepared and convenient to use. The carbons in Exhibits 4 and 5 are of silk thread prepared, carbonized and treated as for ordinary lamps made for the Westinghouse Company. One of these lamps is exhausted to as high a vacuum as possible and the other contains nitrogen. The purpose in the preparation of these lamps was to give as severe a test as possible to the tightness of the joints, since any leakage whatever, would very noticeably affect the surface of these carbons of small diameter and cause them to burn out. No signs of burning out were shown at the end of 200 hours in the case of the exhausted lamp, and 138 hours in the case of the nitrogen lamp, after which tests they were removed from the circuit, and immediately packed and brought here for the purpose of entering as exhibits. These lamps were run during their test at about the same temperature as other lamps undergoing test at the same time, and which were the same as used commercially at the present time.

9 Q. Please state how the cost of the Sawyer-Man lamps having the mechanical construction, shown in the patent in suit, if made on a commercial scale, would compare with that of the ordinary incandescent lamp of the present day.

A. The comparative cost would depend very greatly on the amount of light obtained from the lamps in question; the cost of the two kinds of lamp approaching more nearly in lamps of higher candle power. By far the greater number of lamps, however, are of 10, 16 and 25 candle power as used commercially at the present time, so that it will be proper first to consider a comparison of such lamps. I am informed that the cost of producing ordinary incandescent lamps is roughly between twenty and thirty-five cents, according to the exact style of the lamp, the current carried in its incandescent carbon, and consequent size of the platinum wires.
2102 It is customary after such lamps are burned out to throw away the remaining part since the value of the remaining material would be hardly greater than the cost of shipment and

remodelling necessary before they could be again utilized. As a purely commercial matter it has been found that this is the most feasible form of lamp to use. I refer to the form in which platinum wires are sealed in through the glass, as in the old Geisler tubes and radiometers, and experimental apparatus of Crookes and others, well known prior to the invention of Sawyer and Man. The view taken by Sawyer and Man in their work was that a lamp should be so constructed that when the carbon should become destroyed by use the other parts of the lamp might be returned, taken apart, and refitted with a new incandescent conductor for another period of use. Bearing this in mind, it does not appear strange that they were willing to depend upon a more expensive form of lamp than might be obtained by utilizing the knowledge of the day in the sealing of wires through the glass. On the other hand, the expense of producing a lamp of the exact form shown in the patent in suit would not be so great as to prohibit its use on a commercial scale, even if it were not generally returned for remounting. From my experience with such mechanical work, I would estimate that lamps of the Sawyer and Man form, as shown in the patent in suit, could be produced complete in quantities of, say 1,000 or more per day, at a cost of between eighty cents and one dollar each. Of this cost sixty to eighty cents would be that of the permanent mechanical portions of the lamp, allowing twenty cents as outside estimate on the cost of taking apart, preparing and mounting a new carbon, putting together and re-exhausting. I believe it quite possible that on a large scale the cost would not be more than one-half of this amount.

In the case of the larger lamps, of say from 50 to 150 candle power, it is evident that little would be added to the cost of 2103 the lamp of the old Sawyer-Man form, since the changes would be more in weight of material used than in labor, as compared with the small lamp. A lamp of the modern type, however, with the Geisler seal involves a greatly increased amount of labor by the glass-blower, as the size is increased, and runs up rapidly beyond the amount I have estimated, as the cost of the old Sawyer-Man form.

To summarize briefly: lamps of the old Sawyer-Man type could be refitted for use an indefinite number of times at a cost not differing greatly from that of supplying modern incandescent lamps, as is habitually done by the various electric light companies and without very greatly increasing the investment for the installation of a plant in the first place. The cost of installation of an incandescent light plant may be placed at from fifteen to twenty-five dollars per lamp as now practiced commercially. Even an addition of one or two dollars in the amount of this investment would not seriously change the commercial value of the lamp since renewals of carbon would cost practically the same, or less, than the present renewal of the entire lamp.

10 Q. Please state the effect upon incandescent lamp filaments or carbons of the Sawyer-Man hydrocarbon treatment process?

A. I have already referred incidentally, in my answer to question 5, to the effect of such treatment and would refer now to that answer as a part of the answer to the present question. I would emphasize particularly the importance of the tempering process, or internal treatment as distinguished from external treatment or the deposition of a shell of carbon on the surface of the fibrous carbon proper. It is the internal treatment which is by far the more important, since its action is to consolidate the entire mass, rendering the resistance uniform throughout the cross-section, and filling up any slight imperfections that may exist. This action is therefore to render the carbon more homogeneous and dense, at the same time changing in a very remarkable way the elasticity and mechanical strength of the carbon. Incidentally, the resistance of the carbon is decreased by this 2104 process without any increase in the diameter. The resistance, however, of the untreated carbon when prepared of a fibrous material is so high as to admit of such reduction without interfering with the high actual resistance of the filament even though its specific resistance may be lowered. It has been stated that the process of hydrocarbon treatment is substantially building up a filament of deposited carbon on a core of small diameter and of any substance sufficiently good to act as a frame-work or support for the carbon so deposited. While such a method might be used with some success and has I believe been accomplished by certain makers of incandescent lamps, it is distinctly the reverse of the process as employed in the preparation of fibrous carbon in accordance with the Sawyer-Man specification, as I understand it, and have practiced it. The difficulty in building up a carbon in this way is that the deposited shell is of very low specific resistance, while the core is of high specific resistance, the result being an unequal division of the current when the lamp is in operation, and a much larger part of the current passing through the deposited shell and consequently forcing it beyond its proper proportion of work. In the manufacture of incandescents, as I am familiar with the work, any such building up of the outer surface is carefully avoided, and the diameter of the filament is not sensibly changed by the process. I here produce several specimens of carbon conductors prepared for use in incandescent lamps showing the condition of the carbons before and after treatment.

Exhibit Linen-thread Carbon shows specimens of thread of the same size treated and untreated. It can be readily seen by inspection of the exhibit that there is no perceptible thickening of the treated carbon, and yet, the resistance has been reduced by tempering and consolidating the fibres and internal treatment independent of the microscopically thin external deposit from 525 ohms in the untreated specimen, to 260 ohms, in the treated one. These resistances it may be well to note, refer to the entire filament 2105 as prepared for treatment, the length of which was an inch or more greater than the specimens here shown. The relations between the two resistances per unit length is, however, the same, that is, the untreated resistance is about double the resistance after treatment, and this without noticeably changing the thickness.

The Exhibit "Piazava Carbon," shows the result of treating a more dense material, and while the reduction in resistance is not carried so far in this case, yet the effect is sufficiently marked. The resistance before treatment was 36 ohms, while that after treatment was 26, and that without perceptible increase of diameter.

Exhibit "Linen Twine" shows a specimen of the material before carbonization, the untreated carbon, and the same after treatment. There is no measurable difference in diameter, but the resistance is reduced by the treating process from 55 to 17 ohms. The untreated specimen shown has a slightly higher resistance than had the carbon subjected to treatment, namely, 63 ohms.

The Exhibit "Silk Carbon," shows the result of treating a piece of carbonized silk .005″ in diameter, as ordinarily done in the commercial production of carbons for incandescent lamps. The resistance of a loop of this carbon when measured before treatment is 1,050 ohms. After treatment, the same piece measures 315 ohms, the length and diameter remaining the same.

I have referred in my answer to question 5, and in some detail, to one of a number of experiments I have made to ascertain the effect of attempting to treat Carré carbon such as is used in certain lamps of European manufacture. I have also there described the character of this carbon as to structure, and indicated the method used in its manufacture. I here offer in evidence a specimen of this carbon, which is in fact the identical one used by me in the experiment referred to in answer to question 5. I produce it for the purpose of showing that it is externally treated so as to present about the same appearance as the fibrous carbons offered 2106 in evidence, and that such a deposit does not cause a reduction in the resistance. This is direct evidence to the effect that the fibrous carbon absorbs and decomposes within its pores the hydrocarbon gas during the process of treatment, and is therefore specially fitted to be used in connection with this process. The proof lies in the fact that the fibrous carbons may be reduced to from one-half to two-thirds in resistance without change of diameter, while the Carré carbon when subjected to the same conditions is practically unaffected.

Counsel for complainant offers in evidence the carbons mentioned in the last answer as follows:

Complainant's Exhibit Linen Thread Carbon, W. T. F., S. E.
Complainant's Exhibit Piazava Carbon, W. T. F., S. E.
Complainant's Exhibit Linen Twine Carbon, W. T. F., S. E.
Complainant's Exhibit Silk Carbon, W. T. F., S. E.
Complainant's Exhibit Carré Carbon, W. T. F., S. E.

11 Q. Have you examined the Patent Office model of the patent in suit, and if so, will you please state the dimensions of the carbon contained within?

A. I examined this model on the 30th of March of this year, and measured with a thousandths *guage* the dimensions of the carbon.

The thickness I found to vary slightly, the average being .043″. The width at the top of the loop is .075″. The condition of the carbon was such that it was impossible to tell exactly the width of the arc, but judging from the position of the clamps and their distance from each other, it was about $\frac{7}{16}$ of an inch. The shape of the cross-section was not quite rectangular, but was slightly 2107 rounded at the corners and somewhat wider at one side than the other. Its appearance was such as to indicate that it had been made of treated blotting paper. The carbon in the model had been broken before I saw it, so that it was impossible to get all the dimensions accurately. It seemed to be of about uniform cross-section throughout its length.

12 Q. Please state the circumstances under which you saw the model.

A. I saw it in the office of Mr. L. E. Curtis, 120 Broadway, New York, on the date previously mentioned, in the custody of Mr. Emery, of the United States Patent Office, who brought it to New York for inspection.

13 Q. Can you produce a carbon for an incandescent lamp of the same form and dimensions as that of the model of the patent in suit? If so, please do it.

A. I here produce a carbon which I have made, having very nearly the same cross-section as that in the Patent Office model. The thickness of this carbon is .040″, and the width is .080″. These dimensions give very nearly the same cross-section as that of the Patent Office model. The length of this carbon, however, is somewhat greater, as it was made to fit clamps standing somewhat farther apart in the lamp than those in the Patent Office model. It was made shortly after I saw the Patent Office model, the object being to reproduce as nearly as possible the original carbon and ascertain how it would operate in one of the lamps we were then constructing; as the mechanical parts for these lamps were finished, it was made of a sufficient length to fit. The current would not be practically changed by this alteration in length. This carbon was put into a lamp, which, for some reason, probably a loose-tube bolt, leaked when it was first put on the pumps, and a day or two afterward, when placed in another lamp, was exhausted on the pumps and current was passed through it for a sufficient length of time to satisfy me that the lamp would be perfectly practicable with a carbon of that size. In attempting to tighten the 2108 flanges at the bottom of this lamp while it was on the pump I cracked the bottom flange and could not make it air-tight after that. Such accidents as this are not unusual in any experimental work; but this was particularly unfortunate, as it occurred when I had no further time to correct the trouble.

Counsel for complainant offers in evidence carbon mentioned in witness' last answer as Complainant's Exhibit Blotting Paper Carbon Like Carbon in Patent Office Model.

14 Q. Please state what kind of clamps the Patent Office model has.

A. The clamps were of carbon faced with platinum foil at the parts where contact occurred with the ends of the carbon conductor.

15 Q. How closely did you give your personal attention to the construction and tests of the lamps which you have referred to in your examination, and to the carbonizing of the various materials, samples of which carbons you have offered in evidence?

A. I devoted almost my entire attention to this work during the time it was being carried on; was present at nearly all of the tests; did much of the work with my own hands; and was constantly present observing the progress of the work, and personally supervising such as I did not do myself. I personally carried out one or more times each of the several operations in the preparation and mounting of the carbons, setting up the lamps, exhausting or filling with nitrogen, measuring of the electrical energy consumed and connecting in circuit for test. I did not, however, do all of this work in every instance, but depended entirely upon the supervision of Mr. Frank Smith, when I could not be present. There was no time during the progress of the work, when I did not see or have direct information of all the operations carried on.

16 Q. Who was your assistant in this work?

A. Frank S. Smith, who is in charge of all the experimental work in the lamp department at Pittsburgh.

2109 17 Q. Did you ever visit the works of the Sawyer-Man Electric Company in New York in regard to the manufacture and trial of similar lamps? If so, for what purpose?

A. I first learned of the work at the Sawyer-Man factory in this direction on March 6th of this year, at which time I saw preparations for filling lamps with nitrogen and several of the partly completed lamps. I visited the works two or three times after this and saw some of the lamps burning.

18 Q. Please state whether you gave any directions about the experiments at the Sawyer-Man factory.

A. Yes, I gave directions on one visit to Mr. Packard to try some of the lamps that were then running with a little more current to see how they would stand it. I helped Mr. Packard adjust the current until the lamps appeared quite bright in daylight in a well-lighted room. Mr. Packard thought it was rather a severe strain on the lamps, and said so at the time; but I told him to let them go and see what would happen.

Adjourned to meet Monday, April 22nd, at 10.30.

New York, *April 22nd*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, Esq., of counsel for complainant, and Walter K. Griffin, Esq., of counsel for defendant.

19 Q. Please state how the lamps you saw at the Sawyer-Man factory were burning?

A. They were burning at a fair incandescence.

20 Q. Please state what is the object of the use of nitrogen gas in an incandescent lamp, and what its comparative utility is?

A. The use of a vacuum in the enclosing chamber surround-
2110 ing an incandescent carbon is the best means of preserving
the carbon from deterioration. It is practically impossible, however, to obtain by any known means an absolutely perfect vacuum, the nature of the process being such that a little of the original atmosphere, whatever that may have been, is always left. It is quite evident that if the means of obtaining a vacuum are imperfect it is much better that the residual gas should be some inert gas, such as nitrogen than an active agent like oxygen. The air of our atmosphere being composed of nitrogen and oxygen leaves as the residual gas after exhaustion a small amount of each of these gases, and if the exhaustion is not very high, enough oxygen remains to cause rapid injury to the carbon. It is manifestly much better that all of the remaining gas should be nitrogen than a mixture of nitrogen and oxygen; hence nitrogen becomes a useful means of obtaining a sufficiently low exhaustion so far as oxygen is concerned, and is necessarily present even when it is not purposely introduced into a lamp, since it is a constituent part of the atmosphere. It is possible without the use of a vacuum pump to displace the air from the lamp and substitute nitrogen for it, in which case the use of nitrogen takes the place of the vacuum pump.

The use of an atmosphere of nitrogen of any considerable pressure in a lamp, reduces the efficiency of the lamp, and is therefore not desirable if its use can be easily avoided and without danger of the introduction of oxygen. If, however, there is any doubt as to the ability to obtain a practical vacuum, there is no question that the safest means is to fill the lamp with nitrogen and then withdraw as much as the apparatus obtainable will admit.

21 Q. Is the use of a nitrogen atmosphere in an incandescent lamp fatal to its practicability?

A. Not by any means. I have made successful lamps containing an atmosphere of nitrogen, and run them for several hundred hours at ordinary incandescence. The action of nitrogen on incandescent
carbon is a matter upon which, I believe, chemical science
2111 up to the present time gives little or no information. It has
never been proven, I believe, that carbon and nitrogen can be combined directly, and without the aid of other elements. It is certain that if there is any action of the nitrogen on the carbon it is very gradual and does not prevent obtaining a useful commercial life in an incandescent lamp having a nitrogen atmosphere.

22 Q. I call your attention to the patent in suit. Is the carbon conductor there shown of the same size as the carbon conductor in the Patent Office model compared to the size of the globe in each case?

A. I find by measuring the drawing and lamp globe that I consider to be the same size as the Patent Office model, that the lamp is there shown in general at about full size. By measuring the carbon as shown in the drawing I find its width to be .085″ and its thickness to be .0 6″. My measurement of the carbon in the Patent Office model gave for its dimensions .075″ in width, and .043″ in thickness, the cross-section being somewhat less than the product of these two, owing to the rounding of the corners. Neglecting the rounding of the corners, the cross-section of the carbon shown in the drawing is 1.72 times the cross-section of the carbon in the Patent Office model, and including the rounding of the cor-ers in the estimate, the cross-section would be very nearly 2 to 1. That is, the area of the carbon in the drawing is about double that of the carbon in the model. Fig. 2 is not on exactly the same scale as figures 3 and 4, the carbon therein being draw- relatively a little larger.

23 Q. What effect has the running of an incandescent lamp above candle power upon the life of the carbon?

A. The effect of increasing the current through a given lamp carbon is to shorten its life. The shortening of the life of the lamp for even a moderate increase in the amount of light given is very marked, and to double the amount of light obtained from a given lamp would shorten its life to less than one-tenth part of what it would be at normal candle power.

2112 24 Q. From your experience with Sawyer-Man lamps made in exact accordance with the patent in suit, what is your opinion as to their durability?

A. The life of such a lamp could probably be made as great as that of modern incandescent lamps assuming the same dimensions of the carbon in each case. If the carbon is short and thick, as in some of the lamps made by Sawyer and Man, the mechanical strength of the carbon would be increased, but at the same time the loss of electrical energy due to the rapid conduction of heat away from the carbon would be of some disadvantage and consequently, the expenditure of energy to obtain a given amount of work from the carbon would be greater. Allowing this increase of energy to be made, the life of the carbon would not be seriously affected, and, indeed, might be greater in the case of a thick carbon than a thin one. The relative life of two incandescent lamps can hardly be considered apart from their relative efficiencies; that is, their comparative light-giving power in proportion to the energy expended, and the point I wish to make clear is that a carbon requires more energy in proportion to the light it gives when the length is quite small as compared to its cross-section owing to the conduction of heat at its contact, than does a long thin carbon where this loss is comparatively small.

25 Q. From your experience in the manufacture of lamps like the patent in suit, what is your opinion of the amount of difficulty and trouble you had in making such lamps as compared with any other new line of work in connection with electric lamps or other electrical appliances.

A. The results of our work were uniformly satisfactory compared with similar work of a new character. The number of failures was small compared to the successes, when it is considered that all of the work was new to those who had it in charge.

26 Q. You have put in evidence certain lamps having the usual form of bulb and provided with carbons made from various
2113 woods and textile materials—twelve in all. Are these the only specimens of those particular kinds of lamps which you made and tested?

A. No; these lamps are only about one-fourth of the whole number, all of which were subjected to the same test as these offered in evidence. Of the entire number made only two have been burned out, one of these having been tested at about double its normal candle power, and the other was defective. Of the lamps not tested for durability only two or three of all those made were at all noticeably inferior to the others. This I consider quite remarkable as most of the materials were then carbonized for the first time in my experience. They showed remarkable adaptability for the purpose.

27 Q. Please explain your remark in answer 5, "that without the treating process the availability of carbon as a material for conductors in incandescent lamps is certainly very limited."

A. I meant that only a small number of fibrous and other sorts of carbon would be available in their most useful form without some form of treatment. A great number of vegetable fibrous materials make very good carbons after proper treatment that would not be at all uniform in resistance without treatment; while others, such as hard-carbon pencils and such textile and fibrous materials as thread, paper, bamboo and the like, are useful without treatment.

28 Q. State whether in the manufacture of the Pittsburgh Sawyer-Man lamp, in evidence in this case, any processes or materials not know prior to January, 1880, were used?

A. None to my knowledge.

29 Q. State whether or not a workman skilled in the use of such appliances necessary to make said lamps, could, in your opinion, have made the Sawyer-Man lamps you have put in evidence by the use of the appliances known and at his command prior to January, 1880?

A. I have not the least doubt but that he could.

30 Q. Will you please produce and offer in evidence some
2114 of the raw material used by you in the manufacture of
carbons for the experimental lamps offered in evidence by you?

A. I will, and now do produce specimens of the following substances:

Linwood, rattan, piazava, ixtl or Mexican grass, and bamboo paper. I also offer a piece of split bamboo, such as is at present used in the manufacture of commercial lamps.

Counsel for complainant offers in evidence the specimens of raw material mentioned in the last answer, as follows:

Complainant's Exhibit Linwood, W. T. F., S. E.
" " Rattan, W. T. F., S. E.
" " Piazava, W. T. F., S. E.
" " Ixtl or Mexican Grass, W. T. F., S. E.
" " Bamboo Paper, W. T. F., S. E.
" " Split Bamboo, W. T. E., S. E.

Adjourned to meet at 2.30 p. m.

31 Q. There seems to be some ambiguity about your statement of the lamps made by you in the first part of your answer to question 4. You speak of five lamps being constructed in exact accordance with the drawings and description of the patent, and then refer to five lamps as being constructed mechanically as near like the patent in suit as possible. Please state whether these are the same lamps referred to in the first sentence, and if so, what you mean by the words "as near like the patent in suit as possible," after saying they were constructed in exact accordance with the patent?

A. The five lamps referred to were five of the six referred
2115 to in the first sentence, and I simply meant to reiterate in
the second sentence what was said in the first, and make it clear that the mechanical construction was as nearly a copy of the patent drawing in all essential details as possible.

Direct examination closed.

Cross-examination by Mr. GRIFFIN:

32 X Q. What experience had you in the subject of electric lighting by incandescence prior to 1880?

A. None.

33 X Q. When did your first acquaintance with the art of electric lighting by incandescence begin?

A. My first acquaintance was the experiments I have referred to, in the winter of 1880 and 1881, in the physical laboratory in the Naval Academy at Annapolis, Maryland.

34 X Q. Under whose directions and for what purpose were these experiments then made, and how long did the same continue?

A. They were not made under any one's direction, but I was allowed to use the laboratory there in connection with my work as a student, and I obtained a copy of the Maxim specification describing his process of carbonizing paper. I undertook to see if I could do it.

35 X Q. How many lamps did you successfully make?

A. I had only one lamp globe, and the attached mounting devices. I had several of the carbons I had tested in it, none of which, that I remember of, were particularly successful.

36 X Q. Just the college experiments of a young man of 20, were they not?

A. They were hardly the sort of experiments that were usually made by students at the academy, and would not have been made
had I not been personally interested in the subject.

2116 37 X Q. While you were with the Union Switch & Signal
Company, what was your experience in the manufacture of incandescent lamps?

A. I was engaged as assistant electrician at the time with Mr. Stanley, and carried out much of the experimental work he did at that time on incandescent lamps. I was almost daily engaged in some work of this kind.

38 X Q. What class of incandescent lamps was the signal Co. manufacturing.

A. Silk lamps of Mr. Stanley's type. The switch & signal company had at that time an electric lighting department.

39 X Q. When did you begin to make experiments on the silk-carbon lamps, and when did these experiments end?

A. My own experiments in this type of lamp began with my connection with the switch & signal company which was in the fall of 1884. They have not yet ended, and my work has increased in this direction ever since that time.

40 X Q. When the signal company first began experiments with the silk carbon, whose process of manufacture were they using?

A. I was not there at the time, but I believe they were using Stanley's process.

41 X Q. In what letters patent can I find a description of this Stanley process?

A. Patent No. 323,372, to Wm. Stanley, Jr., and Edward P. Thomson, dated July 26th, 1885, described a method of preparing such carbons. How closely it has been followed I do not know.

42 X Q. Describe generally said process.

A. The process there described consists principally in the chemical treatment of silk thread by the action of a sulphuric acid solution containing sugar and water, followed by drying at a sufficiently high temperature to drive out the water without vaporizing the sulphuric acid, and subsequently carbonizing at a high temperature in a furnace.

2117 43 X Q. And your experiments in connection with this process or modifications thereof have continued up to the present, have they not?

A. Yes, only that my immediate work has not been the actual treating and carbonizing as there described so much as testing lamps that I knew were produced by this general method and by other methods to determine their efficiency and other points of value.

44 X Q. When was the use of silk carbon adopted commercially by the Westinghouse Electric Company?

A. The use of silk as a material for making the lamp carbons grew up with the company: that is, it was the material used at the organization of the company.

45 X Q. How many letters patent have been taken out other than the Stanley patent, for the processes of preparing or manufacturing the silk carbons?

A. I don't know the exact number. Several such patents have been taken out.

46 X Q. And the object of the experiments of the company and yourself has been to improve the preparation and manufacture of these silk carbons up to the degree of perfection at present attained by you?

A. Yes, that is the case.

47 X Q. In reaching the present degree of perfection the company has had to expend a great many thousand dollars, has it not?

A. Yes, it has.

48 X Q. During the time you were first manufacturing those silk-carbon lamps did you not find that a large number of the lamps gave

out, were inefficient in a commercial sense; that is to say, did you not find that their life was very short?

A. Yes, even after we had a great deal of experience in the manufacture of silk carbons.

49 X Q. And this non-success it was your endeavor to overcome by continual experiment, was it not?

A. Yes.

50 X Q. During your connection with the signal company
2118 and the Westinghouse Company you have been a frequent
inventor and patentee of various appliances used in a system of incandescent electric lighting, have you not? And, if so, please indicate generally the number and nature of your inventions.

A. I have made several inventions during my connection with the Westinghouse Electric Co. I think 60 or 70, for some of which I have been granted patents, and most of them have been upon matters pertaining to the generation and distribution of electricity for electric lighting.

51 X Q. Who is Mr. Lodyguine, mentioned in your second answer?

A. He is the same inventor and experimenter to whom some patents have been granted for electrical devices. He resided formerly in St. Petersburg, now in Paris, and is at present in the United States.

52 X Q. Please state the numbers of the prior patents to Sawyer and Man which you for any purpose consulted in order to derive information for your experiments on the Sawyer-Man lamp.

A. No. 205,144 and 210,809.

53 X Q. What patent did you consult for the method of treating the carbon adopted by you?

A. No. 211,262, dated January 7th, 1879, to Sawyer and Man.

54 X Q. In treating any of the carbons did you surround or saturate them by a carbon or hydrocarbon liquid?

A. They were surrounded by hydrocarbon vapor or gas.

55 X Q. What pressure on the air pump was indicated corresponding to the tension of this hydrocarbon gas during the period of treatment?

A. All the treatment was done at very low pressure, say below half or three-quarters of an inch.

56 X Q. That is to say you only had from about $\frac{1}{48}$th to $\frac{1}{64}$th or less of an atmosphere?

2119 A. Yes, that is substantially correct.

57 X Q. As I understand you, your object in treating in this attenuated atmosphere of hydrocarbon gas was to obtain a deposition of artificial carbon within the substance of the material without increase of exterior diameter, or superposition of artificial carbon upon the outside of the material, except to a very slight extent.

A. Yes, so that there could be no question as to the kind of carbon which composed the filament; in other words, I did not want a carbon made up of an internal core and an external shell.

58 X Q. And that carbon composed of an internal core and an external shell was what you sought to avoid, was it not?

A. It was, exactly.

59 X Q. And you sought to introduce the foreign or deposited carbon within the internal core or cavity of the vegetable material used by you?

A. I sought to produce an elastic metallic condition of the carbon characteristic of treated fibrous carbon. The question as to whether gas is internally deposited, or whether the new condition of the carbon is the result of electrical heating in the presence of the hydrocarbon gas, did not enter into the question. What I wanted was a treated carbon that had the characteristics described by Sawyer and Man as the result of treating, and which nobody could accuse of being principally composed of built-up carbon.

60 X Q. And when you treated the pencils of carbon in order to show the difference of effective treatment upon vegetable carbons, the pencils of carbon, you used the same method of treatment which consisted in heating those materials in a highly attenuated atmosphere of hydrocarbon gas, is that not so?

A. That was the principal experiment; but not the only one. The particular carbon offered in evidence was treated in this way.
I also treated others at different pressures of gas with differ-
2120 ent currents, and for longer and shorter times, but found
that while I could deposit an external shell, I could not
render the carbon tough and elastic without thickening it.

61 X Q. But all the methods of treatment adopted by you, were methods of treatment with hydrocarbon gas, were they not?

A. Yes, I do not pretend to say that there may not be some means of changing the physical properties of hard carbon.

62 X Q. This treatment of the carbons in the attenuated carbon gas, was it done before or after the carbons were mounted in position in the lamp?

A. It was done before mounting.

63 X Q. What treatment were the carbons subjected to after mounting and before the lamps were sealed?

A. They were heated to drive off occluded gases.

64 X Q. In what atmosphere were they heated to drive off the occluded gases?

A. Some *in vacuo*, some in nitrogen.

65 X Q. How did the process of treating the carbons adopted by you differ as to its means and apparatus from the method adopted for the treatment of carbons commercially by your own or the connected companies at the present day?

A. I decline to answer that question unless instructed to do so by my attorney, as it involves methods and processes which I cannot make known.

64 X Q. Without asking you to reveal trade or manufacturing secrets, or to give me the full particulars of the method adopted by you in the preparation of the carbons used in your experiments on the Sawyer-Man lamps, I would like to know whether that method of treatment was the same or different from the method of treat-

ment adopted commercially by your company and the connected companies at the present day?

A. While the general process was more like than unlike the 2121 present methods, it is necessary to say that a large number of improvements have been instituted in the methods of treatment; some of which are at present availed of, and which were not indicated definitely in the Sawyer-Man patents. Any such methods as were thought to be in the nature of improvments on the Sawyer-Man method as described in the patent were carefully avoided, and only such precautions adopted as would naturally be presented to any one of average skill and ability.

65 X Q. As I understand you, in treating your carbons for these experiments, you avoided the manufacture of a hard dense carbon, and endeavored to preserve the elasticity and flexibility of the original vegetable carbon as much as was possible; and in order to avoid the accusation of adding a foreign carbon to the incandescent burner?

A. Yes, that is substantially the case. I was particularly anxious to avoid building up a solid mass of deposited carbon independent of the fibrous structure.

66 X Q. And by securing the internal deposit of artificial carbon, you lowered the electrical resistance of the burner to varying extents, depending upon the porosity of the substance treated by you?

A. Yes, that was the case, and I might add, depending also upon the susceptibility of the fibre of the material used in each case for consolidation and tempering, as it is termed in the specification.

67 X Q. And you found that blotting paper, by reason of its loose-matted nature and extreme porosity, allowed the deposition internally of a larger proportion of artificial carbon, and consequently evidenced the greatest diminution of resistance by reason of the treatment?

A. The reduction of resistance in the blotting paper seemed to be partially due to the internal deposition of carbon and partly to some other action of consolidating the fibre, I do not know exactly in what proportion.

68 X Q. And how far this other action of consolidating the 2122 the fibre is affected or controlled by the simultaneous deposition of carbon within the blotting paper, you cannot say?

A. No. All I can say is, that I have succeeded in notably reducing the resistance and hardening and toughening blotting paper when heated in an atmosphere of nitrogen. This I have already mentioned in direct testimony.

69 X Q. When in the art was the process of treating carbon by heating the same in an attenuated atmosphere of hydrocarbon gas, as pursued by you in your treatment of these carbons, introduced?

A. That method is the one described in the patent to Sawyer and Man in which I did not find any specific directions as to the pressure of gas, leaving it to be inferred that the operator can use such pressure as he finds necessary for his purpose. My purpose in this work was to obtain the advantages obtained in the Sawyer and Man specification for the hydrocarbon treatment of a fibrous carbon, and avoid producing any effect which might be construed as something apart from the just claim of the patent in describing the effects as applied to fibrous carbon only.

70 X Q. What specification do you refer to?

A. No. 211,262, and the patent in suit.

71 X Q. Again I ask you when the process of treating the carbons in an attenuated atmosphere of carbon gas was first introduced or known in the art?

A. That I do not know.

72 X Q. And so far as you know is it not true that the present method of treating by hydrocarbon gas in an attenuated atmosphere is a part of all the processes at present adopted?

A. I believe the hydrocarbon gas used where hydro*n*carbon treatment is employed in the manufacture of carbons, is usually more or less attenuated.

73 X Q. And is not the advantage of that attenuation the
2123 fact that it permits the access of the gas to the internal pores
of the carbon, and the gradual deposition under control of
artificial carbon within those pores?

A. I believe those are the principal advantages

74 X Q. Do you find this process described anywhere in the art prior to January 5th, 1880, except as you may find the same described in the Sawyer-Man patent 211,262?

A. No, I do not know of any such description.

75 X Q. Referring you to the specification of that patent, does not that specification direct specifically that the treatment is to be in a carbon liquid and not in a carbon gas?

A. I find in the patent in question, commencing at the next to the last line on the 2d page, the following statement: "But the carbon prepared by our process before it is put in the lamp does not blacken the inner surface of the globe or lamp charged with nitrogen when heated by the current to drive out occult gases during the ingress and egress of the nitrogen, because in that case there is no carbon gas present, and of course, no deposit; and we desire also, to point out the fact that the consolidated homogeneous carbon of our invention may be produced by the electroplating process as well as by the electrical heating of a conductor in a carbon gas or liquid." I consider this ample evidence of the intent of the patentees to employ gas in the treatment of the carbon, and consider it always a matter of judgment as to what pressure of gas should be used. The use of hydrocarbon liquid produces a more rapid effect and is more likely to be superficial, which, I would point out again, I wished to avoid for the distinct purpose of maintaining a fibrous structure and a surface which could be seen to be that of a fibrous material by ca*u*sual inspection.

76 X Q. And you exercised the degree of judgment known to you in the year 1889, did you not?

A. I most certainly did.

77 X Q. Do you find anything in letters patent 211,262,
2124 which directs or points you to the use or treatment of vegetable carbon?

A. No, I do not now recall anything in that patent.

78 X Q. It speaks of the treatment of pencils of carbon, hard carbon, does it not?

A. I do not find in the patent referred to, any limitation to hard carbon. I see beyond the middle of the second column of the 1st page, the following statement: "A pencil of carbon immersed in a hydrocarbon liquid, and heated to an extremely high temperature by the voltaic current, is not itself attacked, but decomposes the surrounding matter, the carbon of which enters and fills up its pores to an extent impossible except with matter in a very attenuated state." I have carefully experimented with the behavior of hard carbon in hydrocarbon gas, and in spite of persistent effort to do so, have failed entirely to produce any evidence of absorption of gas within the interior of this carbon. I have varied the conditions in every way I could think of to produce this result; the carbon always remained granular in fracture, easily broken, and presenting none of the characteristics of what we may term internally treated fibrous carbon. I take this as distinct evidence of the fact that the carbon pencil referred to in the patent in question could not have been of hard carbon, or it would not have been referred to in that way. Sawyer and Man employed carbons in the form of a pencil for some time after the use of fibrous carbon, hence I see no reason to believe that the description was intended to limit the process to hard carbon.

79 X Q. All this little history of what Sawyer and Man did, or did not do, you find set forth in the specification of letters patent 211,262?

A. I find the quotation that I made in my last answer contained therein; but not the remainder of my answer.

80 X Q. Now again I ask you whether the letters patent 211,262 does not specifically direct the use of a liquid, and just as specifically warn the reader against the use of a hydrocarbon gas,
2125 except as that gas exists within the hydrocarbon liquid immediately in contact with the incandescent carbon?

A. The patent, as I read it, while it does direct that the hydrocarbon liquid may be used, contains no warning against treating in the presence of hydrocarbon gas.

81 X Q. That is your impression derived from a study of the patent?

A. I certainly interpreted no part of the patent in that way. That is my impression.

82 X Q. As I understand you, you never used this Sawyer and Man process to create a homogeneous exterior deposit, but confined your treatment to filling up the pores?

A. None of the lamps offered in evidence contained carbon so treated. I, of course, do not wish to be understood as saying that there is no external coating whatever.

83 X Q. How many of the lamps presented by you in evidence

have the metal clip or U-shaped plate or holder at the bases of the arch-shaped carbon interposed between the carbon and the clamps as shown in figures 3 and 4 of the patent in suit?

A. Two of them have sheet platinum interposed as indicated in the drawing: Pittsburgh Sawyer-Man Lamp No. 1, and Exhibit Stillman Lamp.

Adjourned to meet April 23d, at 10.30 a.m.

New York, *April 23d*, 1889—10.30 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

84 X Q. Which of the materials mentioned in the patent 211,262 as operating satisfactorily, to wit: naphtha, turpentine, beeswax, balsam, and most oils, did you employ in treating the carbons in these experiments?

2126 A. In these particular experiments ordinary natural gas was used, as it was found to be a proper and good substitute for the vapor of hydrocarbon liquids.

85 X Q. When was natural gas first used for this purpose to your knowledge?

A. It had been frequently used during the past winter, and has been made use of in an experimental way before that time.

86 X Q. What is the earliest date, of which you know, of the use of that gas for these purposes?

A. I do not absolutely know any date. I believe we were using natural gas at least a year ago; but I cannot fix the date exactly.

87 X Q. I fail quite to understand part of your 10th answer as to the difficulty in building up a carbon by the superposition of a deposited shell. Will you kindly explain the reason of that difficulty so that the court may be able to understand it?

A. The statement may in form be a little confusing; I did not mean to say that there was any difficulty in building up a carbon in this way; but meant to have it understood that there would be difficulty in getting the best results from a carbon so built up, owing to the fact that the deposited carbon is of much lower specific resistance than that of the fibrous core. The division of current would therefore be unequal between the two, and for a given quantity of current passing over the carbon the outer shell would be carrying an unnecessarily large proportion, and the core would carry, perhaps, only a small part of what it was capable of doing. It seems evident that in order to best utilize the entire cross-section of a carbon the distribution of current throughout that cross-section ought to be about uniform.

88 X Q. And as I understand you, it is the object of the modern
manufacturer of carbons for incandescent lamps to secure as
2127 nearly as possible a uniformity of resistance throughout the
carbon and at all points of its cross-section.

A. So far as I am informed I agree with you.

89 X Q. And so far as there is a deposition of an external shell, this tends to prevent the attainment of such uniformity?

A. Yes, I think that is true.

90 X Q. So that experience has shown that the deposition of an external shell is a disadvantage?

A. I would not say generally that it is a disadvantage, because it may be very useful as a means to a certain end where its advantages would greatly overbalance its disadvantages. Some forms of series lamps, for instance, are built up, I believe, in this way to a considerable extent, and with very satisfactory results. To that extent I must qualify my former answer.

91 X Q. But in filament lamps, such as Complainant's Exhibit Defendant's Lamp, I understand you that experience has shown that the existence of an outer shell is a detriment to the life of the lamp?

A. I am not quite sure, after giving the matter a little more careful thought, that this point is recognized by manufacturers of incandescent lamps; but I believe that it is really the case, that a thick outer shell is a disadvantage for a high-resistance lamp.

92 X Q. Exclusive of the Edison Company, do you know any manufacturer of incandescent lamps using vegetable or fibrous carbons of any kind, who does not treat the carbons either by internal nor external deposition?

A. I have never seen a commercial incandescent lamp that I felt sure was not treated, judging simply by its appearance. Such information is very difficult to get.

93 X Q. Referring to the Sawyer-Man patent 211,262, is not the process there described a process for building up the carbons by the external deposition of deposited car*p*on upon the carbon pencils?

2128 A. Yes, such a process is clearly indicated, but I do not see that the patent confines itself to that process.

94 X Q. Do you find anywhere in the patent a description or direction of any method except the method of depositing carbon upon the exterior surface together with the incidental filling of the pores of the material necessarily incident as a stage in the process of arriving at the deposition of this exterior carbon?

A. I find in the second paragraph of the second col*l*umn a fairly complete statement of what the process is considered to be by the inventors. The results of heating the carbon in a suitable hydrocarbon atmosphere are there stated to be the decomposition of the surrounding matter, "the carbon of which enters and fills up its pores to an extent impossible except with matter in a very attenuated state, and deposits a perfectly homogeneous layer, generally of a bright gray color, upon the exterior surface." So far I would say that the filling of the pores by the decomposition of attenuated gas within the carbon is the important feature of the process, the incidental deposition of carbon upon the surface being a necessary consequence of such treatment. By the process as described up to this point I believe the best results are obtained for lamps of moderate candle power for high electro-motive force; but, if it is desired to produce a thicker carbon, the size may be increased, as further described in the same paragraph, by allowing the external coating to become as thick as desired. I would therefore say to complete my answer to this question that I agree substantially with your statement of the case except that I would reverse the relative importance of the external and internal treatment for the reasons that I have indicated.

95 X Q. And you do that because your knowledge at the present time informs you that internal deposition is useful and external deposition detrimental or injurious, is that so?

A. I think I have stated clearly in my answer to a
2129 previous question that for some purposes internal treatment
is desirable, and for others external treatment may be equally so.

96 X Q. Does not the Sawyer-Man patent describe the continuous deposition of an external shell which may be made of such a thickness that carbon pencils may be cut from the material of the shell itself?

A. Yes, I believe the description of the process fully covers that method of producing carbons also?

97 X Q. Before beginning the construction of the lamps at Pittsburgh, how many visits did you pay to the Sawyer-Man factory in this city in relation to the subject-matter of these lamps?

A. One.

98 X Q. With whom were you in consultation there?

A. With Mr. Packard and Mr. Robertson.

99 X Q. Did you not request Mr. Packard or Mr. Robertson later on to send you the results of their experience, and a statement of any difficulties they had experienced?

A. That is my recollection.

100 X Q. And they sent such information?

A. I remember one occasion, and there may have been one or two others, on which they informed me of progress, and I made suggestions with regard to the work.

101 X Q. Subsequently to your beginning your experiments, were you at the New York factory as to this matter?

A. About three times, I think. I went to the factory every time I came to New York, as I had charge of that work in a general way, as well as my own.

102 X Q. What parts, exactly, were sent to you from the New York factory? I mean of the Sawyer-Man lamps?

A. One complete model, which had been prepared after the instructions of Mr. Man, and which I wanted as a pattern to furnish the form to our detail department. A number of glass globes, most
of them imperfect, and some glass plates in about the same
2130 or worse condition. None of these things were used, except
as patterns, and with the possible exception of one or two of the glass parts that were tried before we got others.

103 X Q. How many glass plates did you send to the Sawyer-Man factory in New York? Was it not four dozen?

A. I don't remember. I sent them all I thought they could possibly need, as the glass-makers turned out an ample supply.

104 X Q. How many globes did you send?

A. I am sure we sent a dozen of the last lot I had finished up, because I thought they were good ones.

105 X Q. How many lots did you have finished up?

A. There were two lots, the first of which was defective owing to a misunderstanding of the glass manufacturer.

106 X Q. How many were there in this first lot?

A. I didn't count them, but I should judge about 50.

107 X Q. And how many in the second lot?

A. The second lot consisted of 50 or 100, I don't remember which. I ordered more than I thought we could possibly need, as I did not wish to be interrupted by a stoppage of supply. The number has entirely escaped me.

108 X Q. How many glass plates did you have made?

A. About the same number as there were globes; I think, perhaps, one hundred and fifty.

109 X Q. How many sets of metal clamps or carbon-holders?

A. There were two sets of platinum clamps and 25 or 30 pairs of carbon clamps, as nearly as I can remember.

110 X Q. How many paper carbons did you carbonize?

A. I have hardly any idea. Our practice was to cut out a handful of paper carbons at a time and no particular count was kept of them. They were carbonized in the same way without counting.

111 X Q. How many times did you carbonize paper carbons?

A. Three or four times, I believe.

112 X Q. Do you remember the number of times?

2131 A. That is as nearly as I can remember.

113 X Q. How many blotting-paper carbons did you carbonize?

A. Oh, I suppose 200, possibly not more than half that number. We carbonized a great number of each kind before we were ready with the mechanical parts of the lamps, and then used such as we wanted afterwards.

114 X Q. Of the lamps No. 1 to 10 presented or referred to by you on direct, you state that certain of them had paper carbons. Was this bristol-board carbon?

A. Yes; they were all bristol-board, I believe.

115 X Q. Who did the carbonizing of the various materials used by you in these experiments?

A. I did part of it myself up to the point of placing the crucibles in the furnace, and watching the furnace and removing the carbons from it. Mr. Frank Smith did some of it, and afterwards some carbons were packed for carbonization by the man who has that work regularly in charge. That was after he had seen us do it and knew what we wanted done.

116 X Q. How many hands are employed by the Westinghouse Company?

A. The last time I inquired I think there were about 800 on the pay-roll of the factory.

117 X Q. And your factory has a complete outfit for most extensive manufacture in all mechanical and electrical details of all machines and appliances incidental to a complete system of electric lighting, has it not?

A. It is so considered, I believe.

118 X Q. And you have general supervision over all the electrical work done by the company, have you not?

A. Yes.

119 X Q. Of what department in the factory is Mr. Frank Smith in charge?

A. He is now in charge of experimental lamp-work.

120 X Q. How many hands are employed in that department?

2132 A. That would be very difficult to say, as the number varies very greatly from one time to another according to the needs of the work; but there are always about a dozen people engaged in such work.

121 X Q. You state that you have been associated for 18 months with Mr. Lodyguine, the well-known European electrician, and obtained much useful information through him. To what departments of lamp-work did that information apply?

A. To the carbon conductor.

122 X Q. What carbon conductors did he give you information about as having been successfully used by him in Europe?

A. Carbons prepared of ixtl, or Mexican grass, piazava, rattan, fibre of the large stem of the palm tree, linden, hemp, flax, jute, dogs-grass (Fr. Chien dent), nettle-thread, birch, poplar, ash, willow-tree, basket willow, cotton, manilla, broom-corn, yew, alder, elm, wild ask, aspen, tulip, and thistle-grass, besides others.

123 X Q. And it was for purposes of such information that your company employed or imported Mr. Lodyguine, was it not?

A. He came in the first place to negotiate the sale of certain patents, and has remained to develope those inventions. I obtained this information from him only recently; that is, in full.

124 X Q. I understand that in preparing the paper carbons, you cut them out with circular punches or dies and that in preparing the willow carbons you cut them first in long strips and then steamed them until they were sufficiently soft and pliable to enable you to bend them round a suitable shaped carbon block and to fix them in that position before carbonization. Is that so?

A. Yes.

125 X Q. The silk carbons used by you were silk carbons made and treated by the various processes used in the commercial
2133 lamps of to-day by the Westinghouse Co., were they not?

A. Yes.

126 X Q. Why didn't you cut out the willow carbons with a circular die or punch?

A. It did not occur to me to do it, and I had no willow wide enough to do that with if I had wanted to.

127 X Q. In what form was the willow given to you?

A. It was in the form of splints such as basket-makers use, and some of the pieces had been subsequently split up into smaller pieces.

128 X Q. When was the first time you ever used piazava in an incandescent lamp?

A. I never used it until I tried it for the purpose of this examination. I had seen it before, however.

129 X Q. You stated something in your direct examination as to the use of nitrogen gas. Do you know of any commercial lamps to-day in which nitrogen gas at or near atmospheric pressure is used?

A. No.

130 X Q. Do you know of any commercial lamps to-day which have an attenuated atmosphere of nitrogen gas?

A. Well that depends a little on the view taken of the question. The intention is, I believe, to remove as far as possible all traces of nitrogen, oxygen and other gases of the atmosphere. All lamps, however, contain a highly attenuated atmosphere of these gases, since it is utterly impossible to remove it.

131 X Q. In other words, you do not know of any lamps having attenuated atmosphere of nitrogen gas except as such gas is present necessarily in an attenuated atmosphere of air?

A. I do not know of lamps of any other sort, although I believe a certain German lamp, whose name I have forgotten, contains some such gas.

132 X. Q. You stated in answer to question 21, that you have made successful lamps containing an atmosphere of nitrogen.
2134 To what extent were those lamps exhausted?
A. They were exhausted to pressures varying from a little over half an inch to about an eighth of an inch mercury. I have filled lamps at about atmospheric pressure also; but they were not the ones referred to in that answer.

Adjourned to meet at 2 p. m.

133 X Q. Are not the incandescent lamps universally adopted at the present day, lamps in which an atmosphere of air is exhausted to the highest possible degree of tenuity?

A. I believe so.

134 X Q. Do you know of any commercial lamp which is, or for some years has been, in use, in which the glass globe is composed of two separable pieces, as distinguished from a glass globe the parts of which are fused together so as to become a continuous mass?

A. No, I do not.

135 X Q. Have you any knowledge of the stopper lamps, consisting of a glass globe and separable glass stopper ground to fit the same, which were at one time put on the market by the American Electric Light Co. of New York City?

A. I have not.

136 X Q. Turning to the Sawyer-Man lamps presented by you, please make a sketch showing definitely the construction of the stop-cock in the base of those lamps?

A. In answer to your question, I would prefer to offer in evidence a lamp that was broken, and which shows the condition of the lower part of the lamp before it is exhausted. The attached lead tubes are the same as were used in our work for the purpose of filling and exhausting. The valves in this lamp are the same as were used in all of the lamps of this form made by us.

137 X Q. What is the size of the aperture in the bottom tube? Is it uniform with the aperture shown at the end of the tube just above the glass plate?

A. Yes, it is of that diameter throughout its length.

2135 138 X Q. And the stopper is of very much larger diameter than the tubular aperture through which the nitrogen flows?

A. Yes, it is.

139 X Q. And the stop-cock is made cone-shaped, being less in diameter at one end than at the other, is it not?

A. Yes.

140 X Q. Look at the drawings of the patent in suit and state how the size of the gas tube in your lamps compares with the size of the gas tubes shown in the drawings in the patent.

A. That in the drawing in the patent is larger, I think, than the one used in our lamps.

141 X Q. The gas tube in figure 5 is about twice the diameter, even in that reduced figure, of the gas tubes in your lamps, is it not?

A. Yes, it is.

142 X Q. And the glass globes, or bells, in your lamps, are of the same diameter as shown in figures 3 and 4 of the patent?

A. It is substantially.

143 X Q. If figure 5 were drawn on the same scale as figures 3 and 4, what would be the difference in diameter between the gas tubes of the size shown in the patent and the gas tubes used in your lamps?

A. The diameter of the tube in the drawing would then be about three times the diameter of the tube used by us.

146 X Q. And how does the diameter of the stop-cock used by you compare with the diameter of the screw used to close the gas tube in the drawings of the patent?

A. It is between two and three times the diameter, and would, if the drawing were full size, be, I suppose, one and a half to two times the diameter.

2136 147 X Q. So that, compared with the size of the gas tubes, your stop-cock is about six times as large as the relative sizes of the stop-screw and gas tube of the drawings of the patent in suit?

A. Yes.

148 X Q. The stop-screws in the drawing of the patent in suit are substantially of the same diameter as the gas tubes which they close, is that not so?

A. Yes, I believe so.

149 X Q. Whereas, the diameter of your stop-cocks is at least six times the diameter of the tubes that they close?

A. Yes.

150 X Q. And to the bottom of the gas tubes you fused lead tubes leading to the connections with the air-pump or nitrogen apparatus?

A. Yes.

151 X Q. And when the lamp was either exhausted or charged with nitrogen, did you insert the stop-cocks while the lamp was still under pumps or bags?

A. The stop-cocks were always in place. They were turned when it was desired to close off communication with the lamp. This was done while the lamps were still connected to the pumps or bags.

152 X Q. Did you then seal off the lead tube by fusing?

A. No, we found the valves were tight enough to hold without this.

153 X Q. How did you grind the stop-cocks to fit into the tapered cone which received them?

A. They were ground in the ordinary way by coating the surface with rouge, or some other suitable substance as was dictated to the workman by his experience in such matters. I saw the work being done at the time, but gave no special instruction, except that I wanted a valve which would be certainly air-tight.

154 X Q. And your direction to the workman was to make a valve or air-cock which should be perfectly air-tight?

2137 A. The instruction was hardly so general as that. I limited the form of the valve to an ordinary cone valve such as is fitted to gas bags.

155 X Q. Would the small screw shown in the patent, figure 5, be an efficient stop to insure a vacuum in the lamp?

A. I think it could be made so; but it is not a form usually employed for that purpose, nor was it, I believe, at the time the drawing was made.

156 X Q. But if the screw shown in the patent was as a matter of fact used to prevent the egress of nitrogen substantially at atmospheric pressure it might be sufficient, might it not, until such time as the lamp was further sealed?

A. Yes, I think it would also hold nitrogen, and much more readily than it would preserve a vacuum.

157 X Q. Having regard to its size and proportion in relation to the gas tube which it closes, it is not a form of stop which you would ever think of using as a means of retaining a high vacuum in a lamp, is it?

A. Yes, I would undertake to maintain a vacuum with a valve of that kind long enough to complete the seal; but I do not think it would be nearly so good as the cone valve. There would be much greater chance of failure.

158 X Q. Turning to the upper part of the lamp, I notice in your direct testimony, that you described the U-shaped clamp or holder within the larger clamp as a platinum clamp, or a bent piece of platinum. By what means do you arrive at the conclusion that that bent piece was platinum?

A. I saw it in the Patent Office model.

159 X Q. Do you understand that this clamping piece shown in the drawing of the patent is anything different from the clamping piece which you say forms part of the lamp sent to the Patent Office as a model lamp of the patent in suit?

A. The only difference that I know of is that the drawing
2138 shows a much thicker piece than the pieces of platinum used
in the Patent Office model. The purpose is evidently substantially the same.

160 X Q. What material are the large clamps in the Patent Office model?

A. They are made of carbon.

161 X Q. As I understand you, in only two of the lamps made by you, did you make use of these small pieces of platinum?

A. Yes, that is correct.

162 X Q. How many additional surfaces of contact at the clamps is caused by the presence of these platinum clips?

A. The number is doubled, I should say.

163 X Q. That is to say by the use of the platinum clips, there results twice the number of surfaces between which efficient electrical contact has to be made at the clamps as compared with the omission of the platinum clips?

A. Yes.

164 X Q. What is the law governing the production of heat at points of contact, such as points of contact between the carbon arch and the clamp, first, as regards the resistance of contact, and secondly, as regards the force or intensity of the current?

A. The general law would be that the production of heat varies directly as the resistance and directly as the square of the current where the resistance remains unchanged, leaving out all other considerations.

165 X Q. That is to say, taking two identical Sawyer-Man lamps which vary only as to the resistance at the clamps, the amount of heat developed at the clamps in one lamp as compared with that developed in the other, would vary directly with the resistance of those clamps?

A. Yes, with the same current.

166 X Q. Is it not also true that the heating effect upon
2139 any body by a radiant source of heat in air or *vacuo* diminishes
as the square of the distance between the source of heat and the body to be heated?

A. Yes.

167 X Q. So that a radiant source of heat at twice the distance has only one-quarter the effect it would have at unit distance?

A. Yes.

168 X Q. In all commercial lamps of the present day intended for use in multiple arc, as is Complainant's Exhibit Defendant's Lamp, is it not true that the carbons used are of great length compared with their diameter, so that they assume the filamentary character?

A. Yes.

169 X Q. In lamps intended for such use, what is the advantage in such great length and small cross-section?

A. The great length and small cross-section are attributable directly to the specific resistance of the carbon. It so happens that the specific resistance of carbon is such, that for a lamp intended to operate on a circuit of about 100 volts, the conductor of carbon must be quite long in proportion to its diameter. Had it so happened that the specific resistance of the carbon was one-tenth, say, of what it really is, a much longer and much thinner carbon would have been required. And if it had been ten times the actual resistance, a hundred-volt carbon would be moderately short and thick. I would therefore say, that great length and thinness are not so much an advantage of lamps intended for use in multiple arc as a necessary consequence of the conditions of the material of which they are made.

170 X Q. Again I ask you, what are the advantages, as a matter of fact, to the lamp itself by using a carbon of great length as compared with its diameter when using the lamps in multiple arc?

A. The advantage consists in the fact that a sufficiently high electro-motive force may be used to render possible the distribution of current without too great cost in conductors.

2140 171 X Q. Assuming the diameter of the carbon to remain the same, what would be the difference of heating effects produced at the clamps in the Sawyer and Man lamp by using in one case a carbon burner twelve times as long as in the other, the lamp in both instances being raised to the same candle power?

A. The long carbon having twelve times as great a surface would require a much lower temperature to produce the same total amount of light; that is, the light-giving power would be spread out, as it were, over a larger surface. In order to do this a much smaller current would be required in the long carbon than in the short one, while a higher electro-motive force would be required. The total energy required to give the same amount of light would be much greater; that is, the lamp would be less efficient; but the loss at the contacts themselves would be smaller owing to the reduced current.

172 X Q. Now assuming the other conditions the same, what would be the effect upon the heat produced at the clamps by diminishing the cross-section of the carbon burner so as to give the same illumination in both instances, the same illumination per unit surface?

A. That would still further reduce the heating at the clamps, provided the conditions at the contact were the same in each case; that is, assuming that the surfaces in contact remained the same. Since, however, the reduction in the cross-section of the carbon is usually accompanied by a reduction of the surfaces in contact, the comparison cannot be made in any such off-hand way as this. There is, however, no difficulty in so proportioning the contacts as to make a perfectly practicable lamp in either case.

173 X Q. Is it not a fact that experiments and practical use have shown that there is a degree of incandescence beyond which for the same material it is not profitable to go, and which, if exceeded, materially militates against the life of the lamp?

A. Yes.

2141 174 X Q. And is it not a fact that in manufacturing high candle-power lamps, very long carbons are adopted for use?

A. Yes, carbons of great length are sometimes used and sometimes carbons of very short length.

175 X Q. In multiple-arc lamps, are not the carbons of high candle power always used of great length?

A. Yes, I presume they would be so called as ordinarily used?

176 X Q. With which carbon will you have the least heating of the clamps by radiation, in a short carbon or in a long carbon of a loop form?

A. That depends so much on the exact construction of a lamp that it cannot be definitely answered in so many words. There is no difficulty, however, in making the clamps or contacts of either form such that the radiation would be so small as to not seriously affect the commercial value of the lamp. I think, as a matter of fact, however, taking commercial lamps as they go, that there is more loss from this source in very short carbon lamps, like the Bernstein, for instance, (see Exhibit Bernstein Lamp) than in long carbon lamps like the Edison lamp, both of which are commercially successful lamps, I understand.

177 X Q. The Bernstein is a series lamp, is it not, and not a multiple-arc lamp?

A. Yes, it is used in series exclusively, I think.

178 X Q. When was the Bernstein lamp introduced?

A. I don't know; more than five years ago, I think.

179 X Q. Taking a carbon burner or conductor of considerable diameter, have you not noticed that the electric current will take the shortest path or the path of least resistance from one clamp or holder to the other through that carbon?

A. More current will pass along the side of least resistance certainly.

2142 180 X Q. And if in any conductor there is a line of less resistance, more current will pass through this line of less resistance inversely as the resistance?

A. The current will divide itself inversely as the resistance, I believe that is what you intend.

181 X Q. And this variation of the current in different parts of the carbon conductor will render the conductor hotter at places of least resistance, the heat depending upon the current passing through that part of the conductor?

A. That depends altogether on how the parts of high resistance are located with reference to the parts of low resistance; but if they are in parallel throughout, and not in series, the statement is correct. If they were in series, the reverse would be the case.

182 X Q. And in so far as this difference of heating exists in the carbon conductor it has a tendency to dissociate the particles of carbon and shorten the life of the carbon as an incandescent?

A. That is so theoretically, at least in every lamp of the horseshoe-carbon type; but it requires very abnormal conditions, indeed, to develop it to a noticeable extent.

183 X Q. The larger and thicker the horseshoe carbon the greater the liability to this effect?

A. The shorter and thicker radially—yes.

184 X Q. So that in this respect a long fine filamentary carbon has an advantage over a short thick carbon?

A. Such may be the case, yes, if the shortening and thickening are carried far enough.

185 X Q. Look at the Packard Exhibit No. 6, and say whether the condition of the carbon in that lamp does not indicate to you that the intensity of the current has been greater on the inner circumference than on the outer?

A. It looks as if that might have been the case, and I know it was the case in one of the lamps I saw running at the 23d-street factory. The difference in color between the outer edge and inner edge was just noticeable when the lamp was burning.

2143 186 X Q. And the greater the difference between the length of the inner circumference and the outer circumference, the greater the proportion of current which will pass along the shorter inner circumference?

A. Yes, it would not do to make this difference too great for that reason. It would not, at least, make as good a lamp.

187 X Q. And in long thin carbons, such as used in the Complainant's Exhibit Defendant's Lamp, this difference of length between the inner and outer circumference is reduced to an almost inappreciable amount, is it not?

A. Yes, and even in a carbon like that the Bernstein lamp contains.

188 X Q. And the shorter the arch or circled the greater this difference between the length of the inner and outer circumference?

A. For the same width, yes.

189 X Q. So that a short thick, arch-shaped carbon would have this difference to a very much greater degree than a long slender carbon?

A. Yes, that is true; but unless the carbon is made very short or very thick radially, or both, the difference would not be great enough to amount to anything sufficient to affect the commercial use of the lamp.

190 X Q. What percentage of variation between the outer and inner circumference is, from your actual experience, allowable?

A. I never noticed in my own experience any lamp which showed that tendency, except the one last referred to and forming Packard Exhibit No. 6, although I have seen some very short arch carbons in use. I think the proportions in the Packard Exhibit No. 6 are about the limit in that direction, if the best result is aimed at. No doubt, however, a workable carbon could be made with even a greater difference than this.

2144 191 X Q. But your supposition that a workable lamp could be so made is not based on actual experience, but is simply an expression of your present opinion, which might be modified by experience, is that so?

A. Yes.

192 X Q. And as a matter of fact, you have not tested the carbon arch in which the proportional difference between the outer and inner circumference was greater than the Packard Exhibit No. 6?

A. In my opinion, the carbon in Pittsburgh Exhibit No. 1 shows even a greater difference between the outer and inner edge of the carbon, or certainly as great, and I am quite positive that in the case of Pittsburgh Exhibit No. 1 the peculiarity in respect to difference of temperature was not noticeable while the lamp was in operation, or I should have detected it.

Adjourned to meet April 24th, at 10.30.

New York, *April* 24, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

193 X Q. What experiments did you make at Pittsburgh with your Sawyer-Man lamp to determine the electro-motive force or difference of potential in each lamp?

A. They were measured in the ordinary way in the photometer-room at various candle powers or degrees of incandescence.

194 X Q. What was this electro-motive force, as ascertained by your experiments?

A. It varied with each lamp, and was from 12 or 15 volts to about 30, the average being about 20 volts, I should say.

195 X Q. Do I understand that you measured the electro-motive force for the same lamp at different candle powers?

2145 A. Yes, we did that, but what I wanted to say was, that the different lamps were run at different electro-motive force.

196 X Q. What would be the effect of placing one of your Sawyer-Man lamps in a multiple-arc system, such as it used for the Complainant's Exhibit Defendant's Lamp?

A. There is no lamp among the exhibits suitable for as high an electro-motive force as that of the lamp referred to. If placed on the same circuit the Sawyer-Man lamp would require some additional resistance placed in series with it.

197 X Q. As a matter of fact, any of your Sawyer-Man lamps would be very rapidly destroyed if placed in a multiple-arc system such as used with the Edison lamp I referred to?

A. Yes, it would, if placed in such circuit without any resistance or other means of reducing its current to the proper amount.

198 X Q. That is to say, that with the same amount of current passing through the lamp in multiple arc, your Sawyer-Man lamps would very soon be destroyed?

A. The lamp would be destroyed owing to the fact that it would take a much greater amount of current from a circuit of a pressure sufficiently high to run a 100-volt lamp than it would be able to carry, owing to its low resistance. The current would not, however, be the same in the two lamps as your question would indicate, but the lamps would rather be subjected to the same electrical pressure.

199 X Q. And the lower the resistance of the lamp the greater its unsuitability for use in multiple arc in a circuit of higher electromotive force?

A. Yes, assuming that lamps of the same candle power are taken.

200 X Q. And if, as you say, you should introduce sufficient resistance to lower the difference of potential in the lamps to an amount suitable for your Sawyer-Man lamps or other lamps of low
resistance, you would by the fact of the introduction of such
2146 resistance, be wasting just so much electro-motive force con-
sidered as a source or means of incandescence?

A. Yes.

201 X Q. Is it, therefore, not true that in all practical purposes your Sawyer-Man lamp, or lamps of similar or lowered resistance are not practically adapted to be used in a multiple-arc system?

A. That would be assuming that the electro-motive force now used by the Edison Company is as low as could be practically so used for any commercial purpose. I do not believe this is the case.

202 X Q. Returning to the patent in suit, have you measured, or will you measure, the difference in a radius, and, consequently, in difference of length of inner and outer circumference, of the carbon shown in figures 3 and 4?

A. Subject to correction or more accurate measurement, I should say that the outer circumference is about one-third greater than the inner circumference.

203 X Q. Which is the easier mechanical job, the attachment of the radiators or conductors to the upper base plate as shown in figure 2 of the patent, or as shown in the figure as presented you?

A. I would say that there is very little difference except in case the workman did not have a suitable small wrench, in which case he could more easily tighten up the nuts as they are located in the exhibits, than where they are inside between the radiators, as shown in the drawing. I regard the difference as utterly insignificant.

204 X Q. He would require a special wrench or tool to get at the nuts when situated as shown in the patent?

A. I believe workmen of the kind employed on this sort of work usually have among their kit of tools a wrench suitable for this purpose. It would simply be a small narrow wrench of ordinary form, and of a proper size to fit the nut shown.

205 X Q. And suppose you gave the job of attaching the
2147 radiator to the upper base plate to a workman used to this
kind of work, without directing as to where he was to put the
nuts, would he not naturally use the easier method adopted by you or your workmen in your exhibits?

A. Yes, I should say he might very likely do so, although I have been quite often astonished at the inconvenient places in which instrument-makers will locate screws without any apparent reason.

206 X Q. As a matter of fact, the resistance in a circular carbon arc diminishes as the diameter of the arch diminishes, does it not?

A. Yes, other things being equal.

207 X Q. And if the aim and object was to get a carbon of low resistance, it would be preferable for that purpose to use a circular carbon of small diameter?

A. Diameter of the arc, yes. Small diameter of the arc itself would increase the resistance.

208 X Q. And so far as a circular carbon was of increased diameter, other things remaining the same, the effect of this increased diameter would be proportionately to prevent the attainment of carbon of low resistance?

A. If you still mean by increase of diameter, increase in the length of the carbon, that is correct.

209 X Q. And if the object of Messrs. Sawyer and Man in constructing the lamp shown in the patent was to produce a lamp of low resistance was it not the natural means of producing such low resistance to approximate the terminals holding the carbon clamp and so lessen the length of the arc of carbon?

A. Yes, that would be a natural way of accomplishing that result, but it might have been used for other purposes also and for reasons entirely outside of the resistance of the carbon.

210 X Q. But the construction shown in the patent in suit agrees with the construction naturally adapted for a low-resistance carbon, that is, a carbon of short length?

A. It was adapted for a carbon of short length and low resistance such as that shown in the drawing, and also for a carbon of
2148 greater length and comparatively high resistance, as for example those in Exhibits No. 5 and 6 presented by me, and for still longer and still thinner carbon.

211 X Q. The carbon shown in the patent in suit, if of the length shown in figures 3 and 4 and of the thickness shown in figure 4, would have a very low resistance, would it not?

A. Yes, very low for a lamp carbon.

212 X Q. And the distance between the terminals as shown in the patent, agrees with the mechanical construction which would be intelligently adopted for the use of the short thick carbon of low resistance?

A. Yes, it does.

213 X Q. What, in your opinion, would be the comparative resistance of the carbon shown in your Exhibits 4 and 5, as compared with the carbon of the dimensions shown in the patent in suit?

A. Roughly speaking the resistance of the lamps you have referred to, would be at least twenty or thirty times as great, I should say.

214 X Q. What, roughly, would be your estimate of the resistance of the lamp if constructed as shown in figures 3 and 4 of the patent?

A. I should not expect it to be more than an ohm or so, possibly two or three.

215 X Q. That includes the entire lamp resistance contacts and connections?

A. Yes, it was intended to include the entire circuit within the lamp as the question indicates.

216 X Q. And what would be the resistance of the carbon if constructed as shown in figures 3 and 4 of patent, and treated in the same manner that you treated your exhibits?

A. I should not suppose it would be so great as one ohm, and not very much less. In my former answer I placed two or three ohms as an outside estimate which I thought it would possibly exceed.

2149 217 X Q. Take your Exhibit Lamp No. 1, what is the resistance of the carbon in that lamp?

A. About nine ohms, measured cold, four and a half, hot.

218 X Q. Compare the size of carbon in your lamp, figure 1, with the size of the carbon shown in figures 3 and 4 of the patent in suit?

A. The drawing seems to show a carbon about one-third as long, about six or eight times as thick and approximately the same width as the dimensions of the carbon in my Exhibit No. 1. This would make the resistance from eighteen to twenty-four times as great in Exhibit No. 1 Lamp as in the drawing.

219 X Q. Are not the other exhibits as presented by you of a very much higher resistance than your Exhibit No. 1?

A. Yes, Exhibit No. 4 contains a silk carbon intended to be of moderately high resistance, considerable length and thinness, for the purpose of ascertaining the ability of such a carbon to live in a lamp of the original Sawyer-Man construction.

220 X Q. Assuming lamps of the same candle power and efficiency, is it not true that the longer the carbon is made the smaller the current required to operate it?

A. In a general way that is true.

221 X Q. With such lamps having carbons of similar sections, does not the sectional area increase as the squares of the side dimensions of the said section?

A. Yes.

222 X Q. Does not the current required increase nearly as the sectional area increases under the same assumption as to lamp construction as in the last two questions?

A. No. It is more nearly proportional to the diameter.

223 X Q. Take two carbons otherwise identical, one having twice the sectional area of the other, would it not take twice the current, under the previous assumptions, to heat this larger carbon to the same temperature?

A. Not at all.

2150 224 X Q. Is your answer applicable to all forms of cross-section, and if not to what shapes of cross-section do you consider it applies?

A. It applies to all the usual shapes of cross-section employed in commercial lamps, and would be least applicable to a carbon of the form of a very thin ribbon.

225 X Q. Would your answer apply to Exhibit Lamp No. 1, if you doubled the area of your carbon by doubling its width?

A. Only in a slight degree. The current would in that case be more nearly proportional to the cross-section. The reverse would be the case, if the thickness were doubled, in which case the increase in current required to bring the lamp to incandescence would be much less than double the amount previously required.

226 X Q. In the carbon shown in figures 3 and 4 of this patent if we double the sectional area, keeping the sections similar, how much do you think the current would have to be increased to raise it to the same temperature?

A. I don't know.

227 X Q. Would it not have to be more than double?

A. I cannot see that it would. I should say, certainly, less than double.

228 X Q. Assuming the carbon to be clamped as shown in the figures of the patent, the clamp always embracing the same length of the carbon, does not the surface of contact in the carbons at the clamp increase directly as the side dimension of the carbon?

A. Yes, that would be the case, if I understand the question.

229 X Q. Does not the resistance of the contact vary inversely as the surface of contact, that is to say, inversely as the side dimension of the carbon, all other conditions remaining the same?

A. Yes.

2151 230 X Q. Does not the current passing over this resistance vary more rapidly than the surface contact, assuming carbons of similar cross-section, and the same temperature in clamps like the drawing of the patent?

A. Not necessarily, but I think that in most cases that would be so.

231 X Q. In two such lamps would not the heat produced at the clamp contact be greater in the carbon of large section than in the other?

A. It very likely would, but I must add in connection with this and my previous answers that I consider all these limitations as to contacts of the same length and clamps of the same size and form purely hypothetical, and such conditions as would never be contended with in the actual production of a lamp. It is a matter involving only ordinary common sense, to make the contact large enough and good enough for each size of carbon, and I would call attention to the fact also, that a strong thick carbon can be squeezed up very tight in the clamps, thus securing a good contact, while with a small, fragile carbon, great care is required in mounting, and the contact is apt to be loose. This whole question, and the answers I have given to the questions on the same subject preceding, is purely a matter of experience, and the mounting of carbons of any size, even from that indicated in figures 4 and 5, as some Patent Office draughtsman's idea of how large a carbon ought to be, down to the smallest filament used in the highest resistance lamp of modern manufacture, presents no difficulty whatever.

232 X Q. Will not the heating of the clamps by conduction, also be greater in the carbon of large section?

A. Yes. I have in previous answers fully explained this matter as I understand it.

233 X Q. Similarly, will not the heating of the clamps by radiation from the carbon of the shape shown in the letters patent be greater than in a longer carbon than there shown?

A. Yes, most certainly this will be the case.

234 X Q. Will not the insertion of the platinum foil as shown, increase the heat produced at the clamps by the current?

2152 A. No, it reduces the amount of heat for several reasons. In the first place a contact at the same pressure between the platinum and carbon offers less resistance than a contact between two pieces of carbon. In the second place, the pressure can be made greater by the use of platinum, owing to its softness. It is unnecessary to state any others I believe.

Adjourned to meet at 2 p. m.

Resumed at 2 p. m.

235 X Q. At what candle power did you test lamp No. 1?

A. At ten candle power.

236 X Q. At what candle power was it run?

A. I meant by my previous answer that it was run at ten candle power. It was tested at seven and at eleven also.

237 X Q. At what candle power did you test and run lamp No. 7?

A. At one and five-tenths candle power, except one day, when it was run very much higher than this. I suppose at more than 20 candle power.

238 X Q. At what candle power did you test and run lamp No. 8?

A. It was run at 20 candle power.

239 X Q. What were the volts, amperes and watts of lamp No. 1?

A. 14.5 volts, 7.3 amperes, 105.8 watts; 10.58 watts per candle power.

240 X Q. You state that your experiments with treating blotting paper showed a very large reduction of resistance due to the process of treating. Was this not due to the porosity of the blotting paper.

A. Yes, in a large measure.

2153 241 X Q. If it were not for that treatment, would not blotting paper, in your opinion, be eminently disqualified for use in an incandescent lamp?

A. Without treating or something to take its place, I do not think it would be useful; but it makes a remarkably good carbon for lamps of low resistance when properly treated.

242 X Q. But if used untreated and carbonized without treatment, its life would probably be very short, would it not?

A. That would be a mere guess on my part, as I never tried it in that way.

243 X Q. All your electrical knowledge and experience as to incandescent carbons would lead you to assume that such would be the case, would they not?

A. I should think that probable.

244 X Q. Have you had any experience in treating carbons in hydrocarbon oils or liquids, or such substances as melted beeswax, olive oil, etc.?

A. No, I have had no personal experience in treating carbons by direct immersion in a hydrocarbon of liquid form. All such treating with which I have had anything to do has been from the vapor arising from hydrocarbon liquids.

245 X Q. Do you, or do you not know, that when carbon is treated in hydrocarbon liquid by immersion, nearly all deposit is an external shell, the cooling effect of the liquid causing an almost instantaneous deposit upon the external surface of the carbon, so preventing any further internal deposit?

A. That might be the case, I should think, but I do not feel prepared to say that it would under all cond-ti*i*ons.

246 X Q. The more porous the carbon, the greater the variation that can be produced by treatment according to your methods, is that not so?

A. I have previously answered that question about as follows:

> The more porous and the greater the suscept*a*bility to the
> 2154 tempering process and consequent consolidation of the fibres,
> the greater will be the reduction in resistance.

The reduction of resistance is produced, generally, I think, by this consolidation and internal deposition of carbon.

247 X Q. I believe you stated that in the vacuum lamps among your exhibits, you brought the carbons to incandescence *in vacuo* for the purpose of removing the occluded gases. Are you, or are you not, aware that that process is described in and covered by the specification and claims of letters patent of the United States to Thomas A. Edison, dated October 10, 1882, and No. 265,777?

A. I believe after its invention by Sawyer and Man that process was patented by Mr. Edison.

248 X Q. I referred to the process of removing occluded gases *in vacuo*. Do you understand that that process of removing occluded gases *in vacuo* was so patented to Mr. Edison?

A. I have been told that a patent was issued to him. I am not familiar with the patent. The process of driving out occluded gases is described in the patent in suit, whether *in vacuo* or nitrogen I believe to be immaterial.

249 X Q. You stated that it is, or was, known that without the treating process the availability of carbon as a material for conductors in incandescent lamps is certainly very limited. How many materials do you know from your personal experience to be available for that purpose without treatment?

A. I think all substances of a fibrous nature are more or less improved by treating, and it is simply a question of degree and the amount of perfection aimed at in the production of the lamp, and the consideration of cost of production, that would set apart any definite number of substances as belonging to the class considered suitable without treatment. I believe a number of substances could be so used with considerable success, as, for instance, paper, bamboo, several of the grasses, like Mexican grass, and perhaps a few others. I have had personal experience with these materials in an untreated state, and examined their behavior when submitted to an electric current.

2155 250 X Q. When Prof. Stillman was at the Pittsburgh factory what was the reason that he only filled one lamp?

A. He was delayed by the accidental breaking of the sodium retort.

251 X Q. Was the sodium retort all right the day before he came?

A. It was all right on the same day that he came, and had been in use the day before.

252 X Q. You had no reason to think it was going to break, just as he wanted to fill the lamp, had you?

A. No.

253 X Q. In the various fibres used in your commercial lamp globes presented by you during your testimony by what method were the carbons treated?

A. They were treated in the same way as I have already described in connection with the preparation of carbon for the six Sawyer-Man lamps I have produced.

254 X Q. Exclusive of these experiments, have you had any experiment with lamps of the Sawyer-Man construction?

A. None whatever, if you refer to the old type such as the exhibits.

255 X Q. How long were you working on the silk-carbon lamps before they were made a practical success?

A. They were used commercially from about the time I became associated with the switch and signal company. It has always been the aim of Mr. Westinghouse, however, to improve everything about the concern as much as possible, no matter how good it might be at any given time.

256 X Q. How soon after the lamps were filled was the incandescence begun?

A. As soon as the appearance of the sodium indicated that the atmosphere in the lamps was pure. This time would vary according to the speed with which the operation was carried on. Sometimes we did it very slowly and interruptedly, and sometimes they were finished up within a short time, say, two or three hours.

2156 257 X Q. About how long would you allow the nitrogen to flow through the lamp, before sealing off?

A. For perhaps an hour or two.

258 X Q. And how long would the lamps be treated to remove occluded gas, before being sealed off?

A. That was what I meant to say in the last answer. I meant after the current was passed through the carbon.

259 X Q. How long did it take to charge the lamp with nitrogen gas by the Stillman apparatus?

A. As we had it arranged I should say that the amount of time continuously employed in charging a lamp would be about three hours, and after that an hour or two, possibly, for driving off occluded gases: so that about half a day would be required to complete the operation thoroughly. This time might be very much shortened, I suppose.

260 X Q. All your estimates of cost and commercial expense of operation as to the Sawyer-Man lamps are based upon these experiments, as to which you have testified, at Pittsburgh, are they not?

A. Yes.

261 X Q. How continuously were the lamps at Pittsburgh kept incandescent?

A. Almost continuously after they were once started. The current was interrupted, I suppose, on an average of two or three times a day. The lamps ran all night. Those tests were carried on night and day at the Pittsburgh factory.

262 X Q. Was this in the same room as the one in which the lamps were filled?

A. No.

263 X Q. In bringing the lamps to New York how many of them were broken in transit?

A. Two.

264 X Q. Out of how many?

A. Out of twelve. I will here state that the two lamps broken were in a separate package, and were probably broken from some unusual and severe shock.

2157 265 X Q. It has been stated that the Sawyer-Man Company used bamboo carbons for the filaments in their lamps. What portion of the bamboo did they use?

A. I am not personally and practically familiar with the manufacture of lamp carbons from bamboo; but I have learned incidentally that the outer and denser portion of the splint next to the outer shell is preferable where the size of the carbon will admit of its being limited to this part, and I believe that is the part used at the Sawyer-Man factory.

266 X Q. The lamps made by the Sawyer-Man Company are all slender, or filament carbon lamps, are they not?

A. Not all, but nearly all.

Redirect examination by Mr. KERR:

267 R. D. Q. Cone valves, such as were used in the lamps made by you at Pittsburgh, were well known and common at the time of the first experiments of Sawyer and Man in 1878, were they not?

A. Yes; I believe they were.

268 R. D. Q. Have the lamps described by you, and not offered in evidence, platinum interposed between the clamps and the carbons?

A. These lamps did not have platinum clamps or platinum introduced at the contacts.

The broken lamp referred to in answer to question 136 by the witness Shallenberger is now offered in evidence as Exhibit Sawyer-Man Lamp Stop-cock.

269 R. D. Q. Please give the efficiency of any of the other Pittsburgh Sawyer-Man lamps introduced in evidence by you other than No. 1.

A. Lamp No. 2 had an efficiency of 6.6 watts per candle power;
lamp No. 4, had an efficiency of 4.57 watts per candle power as run;
lamp No. 3 had 11 watts per candle power; lamp No. 5 had
2158 7 watts per candle power; lamp No. 6 had 7.5 watts per candle power; each of which compare favorably with many lamps commercially used at the present time.

260 R. D. Q. What do you mean by your remark in reference to the efficiency of commercial lamps which closes your last answer?

A. I mean by the last remark that these lamps if operated on commercial circuits, would give the same average return of light per horse-power expended as many of the lamps now in use commercially, and supplied by some of the largest companies doing business to-day.

2159 NEW YORK, *April* 22, 1889—10.30 a. m.

FRANK STUART SMITH, a witness on part of complainant, being duly sworn, testifies as follows in answer to interrogatories by Mr. KERR:

1 Q. State your name, age, residence and occupation.

A. Frank Stuart Smith, twenty-six, am at present in charge of the experimental work in the lamp department of the Westinghouse Electric Company at Pittsburgh, Pa. My residence is also at Pittsburgh.

2 Q. What experience, if any, have you had in the manufacture of incandescent electric lamps, and in this connection please state first what training you have had in the science of electricity and practical application of the same?

A. I first began the study of electricity in the year 1885 in one of the technical schools of the Lehigh university gaining such knowledge of the theory of the science together with its practical application as is possible in a thorough college course. During the following two years I was often called upon to utilize the information thus gained in connection with its application to exact chemical analysis; thereby gaining a working knowledge, such as can be only acquired from actual experiments. In June, 1887, I took the position of assistant superintendent of the lamp factory of the Westinghouse Electric Company, of Pittsburgh, Pa., giving my entire time for the year following to the manufacture of incandescent lamps in detail, but with particular attention to the preparation and treatment of the carbon conductors for the same. On or about June 1st, 1888, I gave up this work to devote my entire attention to experimental work on carbon filaments under the personal direction of Mr. Alexandre de Lodyguine, of St. Petersburgh, Russia, gaining from him much valuable and useful information. Since that time I have been engaged exclusively in such experimental work.

3 Q. Have you recently made or assisted in making any experimental lamps constructed mechanically in accordance with the patent in suit?

2160 A. I have.

4 Q. Please state when and where these experiments were made and give a detailed account of the same and the result?

A. These experiments were begun about the 10th of March, 1889, at Pittsburgh, Pa., and were carried on until the 17th of April, at which time work was discontinued in order to present evidence in connection with the patent in suit. The object of the work was to determine whether a practical lamp could be made after the specifications of the patent. In our work we adhered as closely as possible in mechanical details to Sawyer-Man patent No. 317,676. Experiments were made to determine whether lamps made after this pattern could retain a perfect vacuum for any considerable length of time. Various forms of carbon were employed, some being burned *in vacuo* and some in nitrogen gas. In the lamps made to contain carbons burning *in vacuo* we have experienced no trouble whatever, the joints in the lamps being easily made perfectly air tight, as tests made at the expiration of several hundred hours prove conclusively. Lamps containing nitrogen gas were also made very successfully, many having burned for nearly two hundred hours without any appreciable deterioration. In preparing nitrogen for these lamps we have employed the reagents as specified in Stillman patent, No. 235,730.

Reference is made to the following lamps which have been entered by complainant as exhibits as the best means of setting forth the results of our work. I have been present during the preparation of all of these lamps, having devoted a large part of my time during the past four weeks to them.

Pittsburgh lamp, No. 1, contains a paper carbon formed after being carbonized in coke dust by Mr. O. B. Shallenberger. It contains nitrogen gas at low pressure, and has been burned 132
2161 hours and 50 minutes. At the end of this time no marked deterioration had taken place, the lamp being removed from circuit in order to take to New York and present as evidence.

Pittsburgh lamp, No. 2, contains paper carbon fastened to platinum electrodes. The carbon has been burned *in vacuo* for 131 hours 20 minutes. At the end of this time the lamp shows perfect vacuum and was removed from test for purpose of placing in evidence.

Pittsburg lamp, No. 3, contains willow carbon, formed by Mr. Shallenberger, carbonized in coke dust, tempered and treated in very low pressure of hydrocarbon gas. It contains nitrogen at low pressure, and has been run 156 hours and 3 minutes, at the end of which time there is evidence of no deterioration whatever, the carbon being perfectly bright, and the glass globe perfectly clear. This lamp at the end of test shows no depreciation so far as condition and quantity of gas contained in globe is concerned, and has been removed at the end of this time to place in evidence.

Pittsburg lamp, No. 4, contains a silk-thread carbon which has been burned for 200 hours *in vacuo*; tests show vacuum to be perfect at the end of this time.

Pittsburgh lamp, No. 5, also contains a silk filament which has run at proper incandescence for 138 hours in an atmosphere of nitrogen, with no appreciable deterioration.

Pittsburgh lamp, No. 6, differs from the others in that the air-tight joint at base of lamp is made in the form of a ground-glass bottle stopper. This lamp was exhausted to very high vacuum and has been run 24 hours and 20 minutes at about 20 candles. At the end of this time the vacuum was still perfect.

Besides these lamps, several other lamps were made and which have not been offered in evidence.

Pittsburgh lamp, No. 7, contains paper carbon, nitrogen atmosphere. Life 43 hours, 52 minutes. This carbon broke at the clamp from imperfect contact, is still bright and clear, globe not blackened.

2162 Pittsburgh lamp No. 8, contains paper carbon, nitrogen at low pressure, burned for 38 hours 45 minutes, carbon bright, globe not blackened, cause of breaking due to fact that carbon was twisted when inserted in clamps, thus being subjected to very severe mechanical strain while being burned.

Pittsburgh lamp No. 9, contains paper carbon, nitrogen gas at low pressure, has burned 47 hours and 14 minutes, defect due to imperfect spot in carbon which was noticed before lamp was put on test.

Pittsburgh lamp No. 10, paper carbon, carbon electrodes, exhausted to highest attainable vacuum. Carbon burned at very high incandescence; accidentally forced to about 100 candle power before placing on test. Life 42 hours and 30 minutes. Cause of short life probably due to this fact. Lamp exhausted April 2d; vacuum good, April 17th.

Besides these lamps a number were made up in the modern form, but with carbons of many different materials, the idea being to determine positively some of the other forms of fibrous carbon that might be employed successfully as conductors for incandescent lamps.

5 Q. You have referred to making a number of lamps of modern form with carbons of different materials. Please state what materials you used, how many such lamps you made, and how they operated?

A. We have made successfully at the first attempt incandescent lamps in which the carbon conductors were made from the following materials:

1. Broom-corn; 2. Ash; 3. Hickory; 4. Rattan; 5. Piazava; 6. Linen thread; 7. Fibre from a manilla rope; 8. Hemp cord; 9. Linwood; 10. Palmetto; 11. Ixtl, or white Mexican grass; 12. Bamboo paper.

The number of lamps made was necessarily limited to the amount of material that could be readily obtained. We chose different materials suitable for making lamps of high and low electromotive force.

2163 Of broom-corn, we made three lamps. The material used was formed upon a carbon block, carbonized in coke dust, then tempered and treated at a very high temperature in a highly attenuated atmosphere of hydrocarbon gas. In preparing these filaments we were enabled to lower the resistance after tempering and treating to about one-half of the original resistance without any appreciable increase in diameter. Two of these lamps ran for 78 hours and 50 minutes, at the end of which time there was no deterioration in candle power, the carbons were bright, bulb was not blackened, the lamp apparently perfect in every respect. One of the lamps constitutes "Complainant's Exhibit Broom-corn Lamp."

Of ash, there were six lamps made. These were planed down to the requisite size, formed upon carbon blocks, and carbonized as usual. They were all tempered and treated in a highly attenuated hydrocarbon gas and mounted in lamps. After running for 78 hours the five which had been put in circuit were removed to make place for other lamps. At the expiration of this test the lamps bore every evidence of being as good as new.

The carbons for the lamps made from hickory wood were prepared in the same manner as the ash; 3 lamps were made. After running on test for 78 hours and 15 minutes, the lamps give no evidence of being at all defective.

From rattan, we made 2 lamps. These were prepared in the manner described for the ash lamps. When put on test these run for 21 hours and 35 minutes, with no apparent deterioration in candle power. These lamps were removed from test at the expiration of this time for the reason that they had to be packed immediately and forwarded to New York.

From piazava 4 lamps were made. The carbons were prepared by simply winding around carbon blocks the fibre without any preliminary preparation; placed on test, ran without deterioration 23 hours and 15 minutes.

From linen thread 10 lamps were made. The carbons 2164 were prepared by winding the thread directly upon a block of carbon and carbonizing in coke dust. They were afterwards tempered and treated at a very high temperature in highly attenuated hydrocarbon gas. By this means we were enabled to reduce the resistance of the carbon in many instances to less than one-third of the original resistance. This material forms a very good example of what may be done in the way of making a lamp of high resistance and high electro-motive force; the latter, in one of the lamps, being as high as 109 volts, for 16-candle power, most of the remainder being from 95 to 101 volts for the same candle power. Seven of these lamps were placed on test, and at the end of 24 hours and 15 minutes two were broken, one from short circuiting in the base, the other, from being run about 8 per cent. too high. The 109-volt lamp is produced as an exhibit.

From manilla fibre we made 8 lamps; the material was obtained by taking a piece of ordinary manilla rope, untwisting and separating the fibres, winding over the carbon form, and carbonizing as above described. This material forms one of the best examples of a material suitable for high electro-motive force incandescent lamps. Three of these lamps were placed on test, and ran for 16 hours and 23 minutes, when they were removed for the purpose of placing in evidence.

Carbons from hemp cord were prepared by taking the ordinary cord, winding upon carbon blocks and carbonizing in coke dust. They were tempered and treated as usual, the resistance being lowered in most cases by such treatment to one-third the original resistance without any perceptible change in cross-section. 5 lamps were made. They were placed on test, and run a proper incandescence for 23 hours and 15 minutes, showing at the end of test no defects.

3 lamps were made from linwood, and tested for candle power.

2165 No test other than this test for candle power was made, for the reason that the lamps were finished just prior to the time when they had to be shipped to New York.

From palmetto 2 lamps were made, and run 23 hours and ten minutes, with no diminution of candle power. The fibre is hard, compact and uniform, apparently well suited for use in incandescent lamps.

5 lamps were made from Ixtl or white Mexican grass; carbons were prepared by taking the fibre, simply wiping free from dirt with a damp cloth, winding upon carbon blocks and carbonizing as usual. By varying the resistance we were enabled to obtain lamps varying in electro-motive force from 43 to 83 volts. There is no change in cross-section whatever due to lowering the resistance, to the extent of 50 per cent.

From bamboo paper 2 lamps were made. The paper was cut in narrow strips, formed and carbonized as specified above, tempered and treated at a high temperature in a highly attenuated hydrocarbon gas. These lamps were successfully made and tested for candle power.

6 Q. What was the nature of the treatment you bestowed upon these carbons?

A. In every instance the carbon under treatment was heated to a very high incandescence in a highly attenuated hydrocarbon gas. The object aimed at being to expel occluded gases, temper the carbon and fill in the pores. A great many measurements were taken with a micrometer gauge of the cross-section of the carbons before and after this treatment. These measurements demonstrated conclusively that but a very minute amount of artificial carbon was deposited upon the surface of the filament, as there was no appreciable increase in cross-section. The effect of the treatment was to make a dense hard carbon of uniform resistance throughout its length and capable of standing considerable mechanical strain.

7 Q. Please state why you did not give the various lamps referred to in your foregoing answers longer tests?

2166 A. On account of the limited time we had at our disposal to make these tests.

8 Q. Please state how the amount of difficulty and trouble you experienced in making these lamps compared with that occurring in connection with other work of the same character?

A. I would say that the construction of the Sawyer-Man lamp, as specified in the patent in suit, was an entirely new character of work for us, as was also the preparation of the different varieties of fibrous carbons which are contained in the twelve exhibits which are made up in the form of a modern type of lamp. Our success was unusual for work of that character which was so entirely new to all engaged in it. In the preparation of the carbons which are mounted in the modern type of lamp, no attempt was made to prepare a filament which did not result in complete success. In making a selection of materials for these lamps, it is simply necessary to be guided by common sense, selecting that material whose well-known properties are apparently well adapted to this purpose.

9 Q. Please state how the Sawyer-Man lamps made and used at Pittsburgh, operated?

A. From the first we had little or no trouble at all from the mechanical details of the lamps. As given in my answer to question 4, we were able to make the joints in the lamps perfectly tight with the exercise of a little care in assembling the parts. This fact being once settled it was a comparatively easy matter to make a good practical lamp. The tests of all these lamps were carried on in the same manner that tests are usually made for the life of modern incandescent lamps. The lamps were all burned at a reasonably high temperature, some of them being at times forced considerably above normal. The lamps were inspected by me during the proces of the tests anywhere from ten to fifteen times per day, and at no time was the temperature of the filament and the consequent candle power too low to make what could be considered a fair test. This test was run alongside with other tests of the same nature,
2167 and I was enabled to judge as to the relative conditions of
the two tests very accurately. The fact that some of these lamps, namely, the last four referred to in my answer to question 4, gave out inside of fifty hours is not unusual. It is a well-known fact that a lamp can be forced to almost any candle power. It is also known that by this means the life of a lamp is shortened in a much greater ratio. It was noted that when these four lamps were put on test that they were burning at a very high incandescence, they were, however, allowed to burn in order to be able to determine roughly in a very short time about what they were capable of doing.

New York, *April 23d*, 1889—10.30 a. m.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

10 Q. Please state whether there is any difficulty in making

practical and operative electric lamps in accordance with the specifications of the Sawyer and Man patent in suit.

A. Judging from the absence of any trouble on our part in making the lamps I would say none whatever. It is simply necessary to exert the same amount of care that is ordinarily employed in the construction of an incandescent lamp.

11 Q. Please state whether or not a lamp constructed in accordance with the mechanical construction described in the patent in suit is, in your opinion, a practical and useful thing.

A. It is.

Adjourned to meet April 24, 1889.

2168 NEW YORK, *April 24th*, 1889.

Cross-examination by Mr. GRIFFIN:

12 X Q. What experience have you had in the art of electric lighting by incandescence prior to 1885?

A. None whatever.

13 X Q. What practical experience of any kind have you had in the art of electric incandescence prior to your going to the Westinghouse Company in June, 1887?

A. None.

14 X Q. Since that date you have been assistant superintendent of the lamp factory of that company?

A. Yes, until I gave up my time after June 1st, 1888, to experimental work.

15 X Q. As I understand, since June 1st, 1888, you have been engaged substantially, exclusively in experimental work preeminently on carbon filaments?

A. Yes, sir.

16 X Q. How many men have been under your charge in the ordinary course of these experiments?

A. Seven men are constantly employed, and at various times the number runs up as high as twelve or fifteen.

17 X Q. The object of this experimental work generally has been the improvement or betterment of the carbon filament used, or intended, or hoped to be used by the Westinghouse Company?

A. Principally.

18 X Q. And the ascertainment of the conditions of preparation, manufacture and mechanical surroundings best adapted for these filaments.

A. Yes, together with the best preparatory processes before being made up into lamps.

19 X Q. In the Sawyer-Man experiments, did you have any parts sent on to you understood to be old original Sawyer-Man parts?

A. There were a few bulbs together with the glass discs for the bottom of the lamp received at Pittsburgh, which, I understand, were from New York.

2169 20 X Q. Did the Sawyer-Man Company send on to you a sample lamp?

A. I believe they did.

21 X Q. You stated that Mr. Lodyguine gave you much useful information as to carbon filaments. What was the general nature of this information?

A. Principally in the direction of the best general preparation and handling of our carbons preliminary to mounting them in the modern form of lamp.

22 X Q. Have you had any experience in treating carbons in a hydrocarbon liquid by immersion, and rendering the carbon then incandescent?

A. I have made a very few lamps by such process.

23 X Q. Did you ever examine the lamp carbon within those lamps to see how far within the interior of the carbon the deposit had extended?

A. I did not.

24 X Q. And you have no personal knowledge how far under such treatment a deposit of carbon would extend.

A. No knowledge derived from actual experiment.

25 X Q. You have testified as to certain lamps made and used in the commercial globe of your company. The carbons in these lamps were all treated, were they not, and treated in a highly attenuated atmosphere of hydrocarbon gas?

A. The carbons for these lamps were all prepared by heating the carbon to a high temperature in highly attenuated natural gas.

26 X Q. Do you know anything of the temperature at which these carbons were carbonized?

A. I can only say that I should judge it was from three to four thousand degrees Fahrenheit.

27 X Q. Are you aware of any commercial lamp on the market having fibrous or vegetable carbon with the exception of such lamps as have bamboo carbons?

2170 A. Yes, sir. The lamp manufactured by our company contains a silk fibre, and there are also commercial lamps, I believe, made from paper or cotton thread.

28 X Q. Are there any lamps having carbons made from cotton thread on the market in this country?

A. I am under the impression that the Swan Company make their lamps from cotton thread.

29 X Q. You mean the Swan English Company?

A. Yes, sir.

30 X Q. Do you know to what treatment the cotton threads are subjected prior to carbonization?

A. I have no personal knowledge.

31 X Q. Do you not understand that they are soaked in various acids and chemicals?

A. I have no knowledge whatever, of that.

32 X Q. The paper carbons you referred to are the paper carbons which are, or have been, manufactured by the United States Company, are they not?

A. Yes, sir.

33 X Q. And these paper carbons are treated, are they not?

A. I don't know.

34 X Q. Do you know that they are made of paper?

A. Only from what I have been told.

35 X Q. And from what you have been told, do you not understand that they are treated?

A. I am under the impression they are; but have no positive knowledge.

36 X Q. Have you any personal experience of any practical use of any vegetable fibrous carbon for use in incandescent lamps which has not been treated?

A. I have made some few lamps from silk fibre which had not been treated.

37 X Q. But none from vegetable fibre?

A. I consider silk fibre a vegetable fibre.

38 X Q. Why do you consider silk fibre a vegetable fibre?

2171 A. For the reason that the production of silk fibre through the agency of the silk worm is derived directly from vegetable material.

39 X Q. On the same principle I suppose you consider the wool of a sheep a vegetable fibre?

A. I believe, in general, silk fibre is called a vegetable material, and wool, animal material. The distinction is, perhaps, somewhat arbitrary.

40 X Q. Then you are inclined to the theory that "all flesh is grass"?

A. Yes.

Redirect examination by Mr. KERR:

41 R. D Q. Please look at the lamp which is marked "Stillman lamp," and state what you know about it.

A. This is the lamp which was filled by Dr. Stillman on April 15th at the Pittsburgh factory, with nitrogen, put on the circuit and tested.

42 R. D. Q. In whose custody has the lamp been since that time?

A. In my own until I produced it here in evidence.

The lamp is offered in evidence as Complainant's Exhibit Stillman lamp, W. T. F., S. E.

And now, to wit, April 24th, 1883, it is stipulated that Edward R. Knowles, if recalled, would testify that Henry E. Vineing was first employed by the complainant on November 23rd, 1883, and that he continued in such employ until June 1, 1884.

It is further stipulated that the signatures of the witnesses Shallenberger and Smith are waived by consent.

2172 *Thomas B. Stillman.*

THOMAS B. STILLMAN, being recalled on the part of the complainant, testifies as follows in answer to interrogatories by Mr. KERR:

165 Q. Please state whether you, at any time or times recently, visited the Sawyer-Man Electric Company's factory in New York;

and if so, whether you there saw apparatus for producing and filling incandescent electric lamps with nitrogen gas?

A. I have. I was there two or three times recently, saw lamps being filled by the apparatus similar to the one I used ten years ago for filling the lamps with nitrogen gas. I don't think that I saw any apparatus for making the gas during these visits. The nitrogen gas was already in the bags made when I was up there. The method of making the gas was the same as I used, however, namely, by chloride of ammonium and nitrate of potash.

166 Q. Please state how long ago these visits were made?

A. One was made about three weeks ago, the other last week, or the week before last.

167 Q. What was the object of your last visit?

A. To fill some lamps with nitrogen gas personally by the same process I used ten years ago.

168 Q. Did you do so, and if not, why not?

A. I could not do so as a portion of the apparatus was broken.

169 Q. Did you see any of the lamps burning during either of these visits, and if so, state whether they differed, so far as you could see, from the lamps you filled in 1879?

A. I saw some of the lamps running that were filled with nitrogen, and I could see no difference in their construction and those I filled in 1879, of the same character.

170 Q. How did they appear to burn?

A. All right.

2173 171 Q. State whether or not you have recently been at the works of the Westinghouse Electric Company, at Pittsburg, and if so, for what purpose?

A. Yes, sir, I was there on Monday of this week, to examine the apparatus used there for filling the lamps with nitrogen gas, to see the lamps that were running filled with gas, and also to see a lamp put together and filled by myself in the same manner as I used before and to see the lamp tested and run after it was filled.

172 Q. What did you do on that visit with reference to making nitrogen gas, filling and testing the lamps?

A. I made the nitrogen gas, purified it, charged the lamp in the same manner as before, and left the lamp running in perfect condition when I left Pittsburgh.

173 Q. How did the apparatus for making nitrogen gas, purifying it, and filling the lamps which they had in Pittsburgh, and which you used on Monday last in the filling of the lamp, compare with the apparatus used by you for similar purposes for Sawyer and Man in 1879?

A. There was no material difference.

174 Q. Please look at the lamp now shown you, marked Complainant's Exhibit Stillman Lamp, and state whether or not that is the same or similar to the lamp you filled last Monday?

A. The lamp is similar to the lamp filled last Monday. I have not seen the lamp since Monday, but I believe it to be the same.

175 Q. You spoke of seeing this lamp put on a circuit and burned. How did it operate?

A. Very successfully.

176 Q. How did its operation compare with those which you filled for Sawyer and Man in 1879?

A. The lamp burned successfully. I can't compare it with the other lamps. The lamp at present is in perfect condition, and a comparison could not be made unless the life of the lamp was given also, that is to say, this lamp may burn six weeks, or two months, as some of the Sawyer-Man lamps did, and this requires a comparison, as I stated before, of the life of the lamps.

2174 177 Q. My question was intended to relate only to the appearance of the lamp while you saw it burning; and I would like to know whether it burned during that period in any way different from the lamps which you tested successfully for Sawyer and Man after filling them in 1879, your test, as I understand, lasting from thirty minutes to an hour at that time?

A. The lamps which I tested in 1879, after filling and during the filling, for a half hour or more in each instance, were brought up to a state of low redness. This, however, stood the test for the same period of time, giving out a much brighter light.

178 Q. How did its appearance while burning compare with the similar lamps you saw burning at Sawyer and Man's factory?

A. I have no means of deciding that point definitely, but I judge its appearance was about the same.

179 Q. Did you see any other lamps of this construction burning at the Westinghouse factory last Monday?

A. I did.

180 Q. How did they appear to burn?

A. All right.

181 Q. Please state why the lamps you tested in 1879 were brought up to a state of low redness?

A. To drive out any occluded gases, and also as a means of testing whether the globe was properly charged, since by keeping the carbon incandescent the nitrogen gas containing oxygen for a half an hour or more, combustion would ensue, which would show itself by the destruction slowly of the carbon. If much oxygen was present, the destruction was very rapid.

Cross-examination by Mr. Griffin:

182 X Q. When you went to the New York Sawyer-Man factory and when you went to the Pittsburgh factory, I understand that the apparatus employed for making the gas and filling the 2175 lamps, was the apparatus and process invented by you and patented to you in two several patents taken out in 1880 in this country. Is that so?

A. No, sir.

183 X Q. What difference was there between the apparatus patented to you and the apparatus you saw?

A. There was no patent for the manufacture of nitrogen gas.

184 X Q. Did you not take out one patent for the purification of nitrogen, and one patent for the process of filling the lamps with nitrogen?

A. Yes, I did.

185 X Q. And one of those patents was numbered 227,530, for your method of manufacturing the gas, dated March 23d, 1880, and the other was numbered 227,454, dated May 11th, 1880, for apparatus for charging the lamps?

A. I believe so.

186 X Q. As far as any difficulty in filling lamps with nitrogen by your process is concerned, do you know any reason requiring your presence and assistance at either factory in order to insure the proper filling of the lamps?

A. No, sir, not after looking over the specifications of the patents.

187 X Q. What would be the effect with your apparatus upon the glass tube holding the sodium, if it was started up and heated, after, by any means, a leakage of air had entered into the apparatus?

A. The sodium would be changed to oxide of sodium and the efficiency of the sodium would be deteriorated if enough air should be allowed to enter the apparatus to combine with all the sodium present. This, however, is a contingency which should not arise.

188 X Q. The special object of your use of melted sodium was to insure the absolute consumption of all air or oxidizable matter before the gas was passed on to fill the lamps?

A. It was.

2176 189 X Q. When you say you saw lamps in New York at the Sawyer-Man factory which were filled with nitrogen, you mean simply that from the surroundings and the apparatus you saw, and what was told you, you saw no reason to doubt the gas was nitrogen?

A. Yes, sir.

190 X Q. Please look at Complainant's Exhibit Sawyer-Man Broadnax Lamp No. 2, already in evidence in this suit, and say whether that resembles any of the lamps you filled in 1878 and 1879.

A. It resembles the lamps; yes, sir.

191 X Q. I also ask you to look at Complainant's Exhibit Sawyer-Man Treating Apparatus, and to state whether that apparatus, so far as regards the radiators, the upper disc, and the arrangements of the clamps, resembles any of the lamps filled by you for Sawyer and Man in 1878 and 1879.

A. My impression is that I filled lamps similar to this in construction.

192 X Q. Are you able to say whether there is any difference in the upper part of that Sawyer-Man treating apparatus, and the lamps which you remember filling?

A. As I stated before, lamps were already set up and in proper condition to be filled with nitrogen gas by me. Otherwise than that I cannot state in regard to this lamp.

193 X Q. You stated that lamps having arch-shaped carbons were filled by you. Can you point out any difference in the radiators, the discs, the uprights, or any of the upper portion of that

exhibit which to your recollection or knowledge differs from the lamps having arch-shaped carbons which you filled?

A. As I stated before, various forms of carbons and lamps were sent down to be filled some containing the *the* soapstone upper base and others containing a metallic base insulated by means of mica. If my recollection is correct, I have filled some of these lamps like the sample; but my impression is that after January, 1879, I saw but few in which the bolt and nut went through the clamps.

2177 194 X Q. Otherwise do you notice any difference between the arrangement in any way, either as to the size or as to the relation of the parts between the upper part of the exhibit just now shown you, and the upper parts of the lamps that you recollect as having arch-shaped carbons?

A. There were a number of small changes made in the lamps from time to time which I do not recollect; but, which if brought to me, I might remember.

195 X Q. When you say that the lamps which you saw at Pittsburgh and New York resembled the lamps which you filled in 1879, you do not mean to assert an identical construction, but in general appearance, they resembled the lamps which you filled in 1879?

A. The lamps which I filled in 1879 consisted of various forms of carbon, and the lamps which I saw running at the New York factory and the Pittsburgh factory were identical in form and construction with some which I saw in 1879.

196 X Q. Do you mean that the lamps were identical in their construction?

A. So far as I could remember I should say that they were identical in construction?

197 X Q. Similarly is the upper part of the exhibit just shown you identical with the lamps which you filled in 1878 and 1879?

A. The lamps which I saw running in the factories in New York and Pittsburgh were identical with some of the lamps which I filled in 1879, but I do not recollect seeing this particular form running in the Westinghouse factory, though they may have been so.

198 X Q. What I want to know is this; whether to the best of your recollection these two lamps, the Broadnax lamp No. 2, presented during Mr. Broadnax's examination by complainant*s*, and the Exhibit Sawyer-Man Treating Apparatus, are more or
2178 less identical with the lamps which you filled in 1878 and 1879, than were the lamps you saw at Pittsburgh?

A. My attention while in the factory in Pittsburgh was drawn more especially to the conditions of the carbons and their rate of burning, than to the exact construction of the upper portion of the lamp, though there is a general resemblance to the lamps filled by me in that regard, consisting of a piece of carbon, arch shaped, or otherwise, as an illuminant, connected between two large anodes or terminals. For this reason there may have been lamps of the description mentioned by you in circuit without my being able to say positively that they were there.

199 X Q. What, again, I want to understand distinctly from you, is this: is your knowledge as to the identity of the Pittsburgh lamps, as to their upper portion, with the lamps which you filled in 1878 and 1879 any more or less accurate than your recollection about a similar identity of the two exhibits that have just been shown you?

A. In regard to the two exhibits I can swear positively to filling lamps of that form, and I saw nothing in the lamps running at Pittsburgh which drew my attention to peculiarity of construction from the lamps which I had filled for Sawyer and Man.

200 X Q. Was there anything in the lamps which you saw at Pittsburgh as to the construction of the upper part, which, to your recollection, differed from the construction of the upper part of the exhibit treating apparatus?

A. As I stated before, lamps of this construction might have been on exhibition there, but the lamp which I filled with nitrogen gas while there, or others similar to it, represented the bulk of the lamps running at Pittsburgh.

201 X Q. What difference do you recollect as to the upper part of the lamps running at Pittsburgh and the upper part of the exhibit treating apparatus?

2179 A. As stated before, some of these lamps may have been in circuit; but the difference between this exhibit and the majority of the lamps running there of similar pattern consisted in the upper base not being of soapstone and no brass clamps through the upper carbons.

202 X Q. What were used at Pittsburg through the upper carbon clamps?

A. The arch was placed down in the carbon holders and contact made by means of platinum.

203 X Q. And what held the clamps together in the lamps at Pittsburgh?

A. To my recollection there were no clamps.

204 X Q. Didn't you see any lamps there with carbon clamps?

A. I do not recollect them.

205 X Q. I ask you to look at the Stillman lamp. Are the clamps there not of carbon?

A. They are.

206 X Q. Then the only difference that you recollect between the Stillman lamp exhibit and the Sawyer treating exhibit is in the change of the material of the upper disc from soapstone to metal with mica insulation?

A. Yes, sir.

207 X Q. And outside of that difference, both exhibits, to your recollection, are equally identical, so far as you can now remember with the lamps you filled in 1878 and 1879 of this type?

A. Yes, sir.

208 X Q. When you filled the lamps in 1878 and 1879, how long did you keep them on the bag, and flow the nitrogen through them before taking them off?

A. It depended upon the number of lamps in circuit, varying from one hour to four, depending upon the number of lamps in circuit.

209 X Q. What was the usual length for the lamps you had on circuit?

A. It would vary. Some days I would have one or two lamps and some days ten lamps.

2180 210 X Q. During the time you were with Sawyer and Man, which type of lamp did they consider in their conversation with you to be their most successful lamp? Was it not the straight-pencil lamp?

A. That was a matter of considerable discussion at all times; but I don't think that that was definitely settled.

211 X Q. Haven't you frequently expressed yourself as saying that Sawyer and Man had considerable more trouble with their horseshoe carbons than with the other types of lamps—the straight pencils?

A. I don't recollect that statement. I know that Mr. Man claimed that if the horseshoe carbon burned so successfully in the old shop for several months, there was no reason why others should not do the same. This old lamp, I know nothing of personally.

212 X Q. To your knowledge, didn't they have more trouble with these horseshoe carbons than with the others?

A. I think not; but I could not state positively on that point for the reason that I never kept a record of the life of the lamps, and as I stated before, I don't think they did at the factory; that is, what we call a time book.

213 X Q. You never knew of their keeping a record at all, did you?

A. I think they would keep a record of a lamp which burned an extraordinary time; but if a lamp broke it would be set up and sent down to be filled.

214 X Q. In other words, when a lamp burned out or broke down for any reason, they would fix it up again and send it down to you to be refilled?

A. Yes, sir.

215 X Q. And you cannot positively state how many times this was done with regard to any particular lamp?

A. No, sir; I can only distinguish between a lamp that had been filled once and a new lamp.

THOMAS B. STILLMAN.

2181 NEW YORK, *April 16th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

Testimony of James W. Packard.

JAMES W. PACKARD, a witness on part of the complainant, being duly sworn, testifies as follows in answer to interrogatories by Mr. KERR:

1 Q. State your name, age, residence and occupation.

A. James W. Packard, age 26, residence New York, I am assistant superintendent of the Sawyer-Man Co.'s lamp factory.

2 Q. Were you ever in the employ of the Consolidated Electric Light Co., and if so, when did you go into its employ and how long did you continue?

A. I was in the employ of the Consolidated Electric Light Co., from the 1st of August, 1884, until the 1st of October, 1888, since which date I have occupied the same position in the same factory, the latter being now carried on by the Sawyer-Man Electric Co.

3 Q. Have you recently made some Sawyer-Man lamps of the pattern shown in the complainant's patent in suit, No. 317,676, dated May 12th, 1885, and if so, state what sources you obtained your information from by which you made such lamps.

A. I have recently made several such lamps, receiving my information entirely from the patent and other patents belonging to the consolidated company issued to Thomas B. Stillman and from personal instruction and various parts of old lamps furnished me as samples by Mr. Man. My information received from the Stillman patent was in regard to the manufacture of nitrogen gas and the process of filling the lamps therewith. In the manufacture of the nitrogen and its introduction into the lamps I have been guided entirely by the information received from the Stillman patents.
The Stillman patent for the manufacture of the gas is No.
2182 225,730, dated March 23, 1880, and the one for apparatus for
charging the lamps is No. 227,454, dated May 11, 1880.

4 Q. Did you make any tests of the lamps made by you, and if so, please make a statement of the same.

A. I completed seven of these lamps containing various forms of carbons, and tested them all. The following is the result of the test:

Lamp No. 1: Carbon made of bamboo; candle power 22, volts 23, current in amperes 12; burned for 240 hours, the carbon was then broken on account of the defective joint between the carbon and the electrode which resulted in an arc at this point, rupturing the carbon. The carbon is yet in good condition.

Lamp No. 2: Carbon paper; candle power 64, volts 29, current in amperes 8; burned 107 hours; the carbon is yet in fair condition, not being broken.

Lamp No. 3: Carbon willow; candle power 70, volts 35, current in amperes 11.6, burned 77 hours. The carbon seems yet to be perfect.

Lamp No. 4: Carbon bamboo; lamp not measured for candle power, burned 190 hours, carbon in fair condition.

Lamp No. 5: Carbon willow; burned 77 hours, carbon in fair condition. This lamp was burned at about 40 candle power, taking a current of about 27 volts and 8 amperes.

Lamp No. 6: Carbon paper, burned 49 hours, carbon in good condition. There was no test of candle power or current with this lamp.

Lamp No. 7: Bamboo carbon; candle power 28, volts 22, current about 8 amperes, burned 30 hours, when the carbon broke apparently from a defect in the carbon itself.

I produce the three first-mentioned lamps showing samples of the three kinds of carbon mentioned, namely, bamboo, paper and willow.

The three lamps referred to in the last paragraph of the foregoing answer are offered in evidence as follows:

2183 Complainant's Exhibit Packard Sawyer-Man lamp No. 1, with bamboo carbon, W. T. F., special examiner, April 16, 1889.

Complainant's Exhibit Packard Sawyer-Man Lamp No. 2, with paper carbon, W. T. F., special examiner, April 16, 1889.

Complainant's Exhibit Packard Sawyer-Man Lamp No. 3, with willow carbon, W. T. F., special examiner, April 16, 1889.

5 Q. Please state what the efficiency of these Sawyer-Man lamps made by you is relatively to the ordinary incandescent lamps at present manufactured?

A. The efficiency at which they burned during test was fair, being approximately 4 watts per candle. The average efficiency of the commercial lamps on the market is about three and one-half watts.

6 Q. Why did you not subject these lamps to longer life tests?

A. These lamps which are not burned out were not subjected to a longer life test on account of a lack of time in which to do so. Two out of the seven were burned out, the others were all burned until the morning of April 15th, when I took them off the circuit to bring them to this office.

7 Q. State whether you have tried the use of nitrogen in an ordinary bulb lamp?

A. I have tried the effect of nitrogen in our ordinary lamps with bamboo carbon, and now produce a 32-candle 50-volt lamp containing a residual atmosphere of nitrogen; it has been burning 126 hours and appears to be in perfect condition.

Lamp offered in evidence as Complainant's Exhibit Packard Bulb Lamp Containing Nitrogen. W. T. F., special examiner, April 16, 1889.

8 Q. State whether the seven lamps of which the Exhibits Packard Sawyer-Man Lamps 1, 2 and 3 are examples, were all filled with nitrogen gas.

A. Yes.

2184 9 Q. Please describe the construction of the lower end of the seven lamps made by you.

A. The bottom of the bulb or tube had formed upon it a heavy flange, and carefully ground to this flange was a glass plate, of the same diameter as the flange, with two holes in it through which the hollow brass electrodes passed. On the inside of the bulb there was screwed to these electrodes the nut to which the conductors inside the lamp were fixed. The electrodes were prolonged on the outside of the glass bottom plate, these prolongations being provided with stop-cocks, which stop-cocks were afterwards covered with a brass cap screwing over them. The flange of the bulb and the bottom plate were clamped together by means of brass rings fitting over them, with paper washers next to the glass, these brass rings being held together by screws. In making the joint between the bottom flange and the glass plate, Canada balsam is used as a cement.

10 Q. Did you make any attempt to follow any particular pattern in the construction of these lamps, and if so what?

A. In making these lamps I was guided entirely by the Sawyer-Man patent and samples of old lamps and parts furnished me by Mr. Man. The lamps I made were exactly like that described in the patent with the exception of two in which I used a rubber washer over the opening in the electrodes, instead of the brass plug for a stop-cock; all the others were provided with the brass plugs. Lamp No. 1 is one of those with the rubber washer. The reason I used the rubber in these two lamps was on account of poor workmanship in the brass stop-cocks I had then on hand.

11 Q. State whether you used any of the old parts supplied by Mr. Man in the construction of these seven lamps.

A. The corrugated conductors used in these lamps were, with the exception of about two sets, supplied me by Mr. Man, as were
2185 also three or four of the glass bulbs and bottom plates. The others were made new, being a precise copy of those obtained from Mr. Man.

Adjourned to meet April 18th, at 2 p. m.

New York, *April 18th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, of counsel for complainant, and Walter K. Griffin, of counsel for defendant.

12 Q. Please examine the Stillman drawings, 1, 2 and 3, and state whether the apparatus used by you in making the gas and filling the lamps differed from that shown in the Stillman drawings?

A. The apparatus used by me differed from that shown only in the form of some of the apparatus, and the progressive arrangement of some of the re-agents. It was practically the same.

Cross-examination by Mr. Griffin:

13 X Q. What has been the nature of your duties as assistant superintendent at the factory mentioned in your second answer?

A. I have taken charge of all the details of lamp manufacture and the general management of the employés.

14 X Q. Who has been and is the superintendent?

A. Since occupying my present position, John M. Robertson has been superintendent.

15 X Q. How many lamps have been manufactured a day under your supervision?

A. It has varied between one hundred per day and three thousand per day.

2186 16 X Q. And you had to superintend the various processes of the manufacture of these lamps?

A. I had.

17 X Q. How many hands are employed at the factory as a rule?

A. Between 50 and about 250.

18 X Q. What kind of carbons have been used in the lamps you have mentioned?

A. Bamboo, silk and tamadine.

19 X Q. What proportion of the lamps have been bamboo?

A. Probably eighty per cent.

20 X Q. How recently were the silk filaments introduced?

A. About fourteen months ago.

21 X Q. How many of the silk filaments used by you have been manufactured at your factory?

A. None of the preparation and carbonization of the silk has been done there. The treatment and preparation of the carbon has all been done there.

22 X Q. What do you mean as to the difference between the preparation of the silk and the treatment of the carbon?

A. By carbonization I mean the mere baking of the filament, by treatment, the hydrocarbon flashing process.

23 X Q. Do I understand then, that the silk filaments were carbonized elsewhere and sent to your factory, and then at your factory treated by the deposition of carbon from hydrocarbon vapor upon the filament?

A. That was the case.

24 X Q. And the tamadine filaments were made by and sent to you from the United States Company, were they not?

A. They were sent from our Newark factory, which was operated by the United States Electric Company.

25 X Q. That was the factory of the United States Company, was it not?

2187 A. As I understand the matter, since we have received these carbons this factory has been owned by the Sawyer-Man Electric Co.

26 X Q. Was it not formerly the factory of the United States Company?

A. It was.

27 X Q. When did you begin to make the lamps mentioned by you in your third answer?

A. It was about two months ago that I started making these lamps. I had previously obtained some of the apparatus necessary.

28 X Q. Which of the apparatus had you previously obtained?

A. The gas-holders, some of the re-agent bottles and a few sample parts.

29 X Q. In making these lamps what study did you give to the Sawyer and Man patent in suit?

A. I did not study the matter especially, merely following the details of the patent and the drawing as closely as possible.

30 X Q. When you made the lamps who gave you the patent?

A. H. R. Garden.

31 X Q. President of the Consolidated Company, is he not?

A. I believe so.

32 X Q. For what purpose did he inform you that he gave you the patent?

A. At that time he merely stated that he wished me to make a lamp according to that patent.

33 X Q. When was this that he gave you the patent?

A. I think in August, 1888.

34 X Q. And when did you begin to make lamps?

A. About the middle of February, 1889.

35 X Q. Who gave you the Stillman patent you have mentioned?

2188 A. It was given to me with the Sawyer-Man patent by H. R. Garden.

36 X Q. For what purpose was it explained to you that the Stillman patents were given to you?

A. I understood that it was desired to show in some lawsuit of the Edison Company, that lamps could be made according to these methods.

37 X Q. Didn't you know in which suit it was desired to show these things?

A. I did not until later.

37 X Q. When did you first learn which suit it was?

A. About the first part of February.

39 X Q. And it was after this time in February that you made the seven lamps you have mentioned?

A. It was.

40 X Q. From whom else, besides Mr. Garden, did you receive instructions as to the purpose of your making these seven lamps?

A. I received no instructions in regard to the purpose of making these lamps, but believe I was informed of it by Messrs. Kerr, Curtis and Shallenberger, and Robertson.

41 X Q. When did Mr. Man first send any of the parts of the lamps to the factory?

A. I obtained these parts from Mr. Man in the middle of August, 1888.

42 — Q. Did you go to him, or he come to you?

A. When Mr. Garden spoke to me of making these lamps, I suggested to him that I should go to Mr. Man, and did so with Mr. Garden's consent.

43 X Q. How many parts did Mr. Man give you?

A. Incomplete parts for eight or nine lamps.

44 X Q. How many globes?

A. About twelve at that time.

45 X Q. And how many later on?

A. About twenty later, part of which only I have retained.

2189 46 X Q. How many globes did you have made for you?

A. I had about 150 made, but found in this lot only about eight good ones, the rest were defective and were returned to the makers. I also received ten globes from Pittsburgh, which were fair, but would not fit our parts of lamps and only two of them were used.

47 X Q. When you returned the 140 globes as defective, how many were sent to you in return?

A. I received two lots of 100 each, and none others after these.

48 X Q. Is this in addition to the first lot of 150 of which you returned 140?

A. No, sir, the 200 was all that we received. The maker acknowledged their defects, agreeing to take them back.

49 X Q. What was the defect in these lamps?

A. The bottom flanges were *on* properly put *out* allowing a leakage between the flange and the bulb, and they were irregular in size.

50 X Q. How did you ascertain that these globes allowed leakage between the flanges?

A. Generally an examination by eye would show seams and holes. Some few were mounted into lamps, and showed leakage when tested with the air pump and vacuum *guage*.

51 X Q. Just where would these defects exist?

A. These globes were not blown in a mold as they should have been; but were made by blowing the plain globe and afterwards attaching to it by hand a flange of glass, the globe being cold would not adhere perfectly to the flange which was in a molten state when applied.

52 X Q. Who manufactured these 200 globes?

A. F. Thills, Sons & Co., of Brooklyn.

53 X Q. Who recommended you to that firm?

A. I knew them personally, having dealt with them before.

2190 54 X Q. Besides this, who suggested to you to go to that firm?

A. I first suggested it myself.

55 X Q. Did you talk about this with Mr. Man?

A. Yes, sir; and he informed me that this firm had made the bulbs for him.

56 X Q. When did he say the firm had made the bulbs for him?

A. He did not state any date; but I understood that it was when he was manufacturing lamps.

57 X Q. You mean when he was manufacturing Sawyer-Man lamps such as shown in the patent?

A Yes, sir.

58 X Q. How many of the globes Mr. Man had given you did you send over to Thills, Sons & Co. as samples?

A. Two.

59 X Q. When the globes came from Thills & Co. were the flanges ground down?

A. They were rough ground.

60 X Q. All of them?

A. All that I saw.

61 X Q. How many base plates did Mr. Man give you?

A. I think about 18 or 20.

62 X Q. In all, or the first time?

A. In all.

63 X Q. Did you have any of *of* these made at Thills'?

A. No, sir.

64 X Q. Where did you have them made?

A. Some were made by John Walter, of, I think, 81 Worcester street, and some were sent to me by Mr. Shallenberger.

65 X Q. How many dozens did Mr. Walter make for you?

A. He made one hundred bottoms.

2191 66 X Q. How many samples did you send him out of the originals which Mr. Man gave you?

A. One.

67 X Q. When were these made?

A. I think it was about the middle of February.

68 X Q. How long after this was it Mr. Shallenberger sent you the bottoms?

A. It was three weeks or a month after that.

69 X Q. Sent them to you from Pittsburg, did he not?

A. Yes, sir.

70 X Q. Thills, Sons & Co. of Brooklyn are large manufacturers of electric-lamp globes are they not?

A. They are.

71 X Q. Globes for incandescent lamps?

A. Yes, sir.

72 X Q. Walker, what does he manufacture?

A. He is a workman who cuts and drills glass in special forms.

73 X Q. That is his specialty in trade, is it not?

A. He is employed, I believe, as a packer, by a plate-glass house during the day, and does odd jobs evenings at home.

74 X Q. How did you come to go to Walker?

A. I was directed to him by James Cavenagh, a glass-etcher on South Fifth avenue.

75 X Q. In what condition were these glass bottoms sent to you by Walker?

A. They were comparatively rough, being cut out of plate glass.

76 X Q. Who ground these glass bottoms smooth at your factory?

A. Our principal glass-blower, a man named Schramm.

77 X Q. The foreman of your glass-blowers?

A. No, sir, our pump-maker.

78 X Q. How long had Schramm been in your employ?

A. About two years.

79 X Q. And you considered him your principal man in glass-blowing?

2192 A. Yes, sir.

80 X Q. Who ground down the glass globes?

A. Mr. Schramm.

81 X Q. How many years' experience do you understand Mr. Schramm to have had?

A. I should say at least ten years.

82 X Q. Did you ever watch him personally grind down these base plates from beginning to end?

A. Yes, sir.

83 X Q. How long did it take him?

A. I should say from about ten to twenty minutes to complete one.

84 X Q. How many did you see him personally grind down?

A. About six or eight.

85 X Q. When did you see him grind the first one?

A. I think it was in August.

86 X Q. When did you last see him grind one?

A. About the first of April.

87 X Q. Where did you go to see him grind them?

A. In what we call our laboratory.

88 X Q. Why did you go to see him?

A. I did not go to see him, but happened to be present while he was doing it.

89 X Q. What do you mean by the laboratory?

A. The first floor of our rear building at 326 West 23d street, which is used for special and experimental work.

90 X Q. Work which you do not wish the ordinary workmen to see?

A. No, sir. Work which requires to be done immediately, and which might interfere with our regular work in the factory.

91 X Q. When was your first experience or knowledge as to the manufacture or construction of incandescent electric lamps?

A. In the spring of 1885, when I went to work in the Brooklyn factory of the Consolidated Company.

2193 92 X Q. And since then you have overseen the manufacture of from 100 to a thousand lamps a day.

A. Yes, sir.

93 X Q. Since 1885 have you not had large experience in the carbonization and treatment of filaments for incandescent lamps?

A. I have had experience with only one kind of filament.

94 X Q. What kind is that?

A. The bamboo filament as used by Sawyer-Man Electric Co.

95 X Q. Are any of the seven lamps which you made, made from the actual parts given you by Mr. Man?

A. Not complete. Some of the parts are used in them.

96 X Q. Take the lamps numbered from 1 to 7 respectively, and state just what parts of each lamp are original parts given you by Mr. Man.

A. I cannot identify them, they having become mixed in with the other parts.

97 X Q. Can you swear of your knowledge that there is any one part of those seven lamps which is one of the original parts given you by Mr. Man?

A. I cannot positively identify any such part, but I am certain that such parts are there used.

98 X Q. How many dozen radiators did you have made at Newark?

A. None.

99 X Q. Where were they made?

A. They were sent to me from the Pittsburg factory.

100 X Q Did you have any radiators or conductors made elsewhere?

A. No, sir.

101 X Q. When did you first put together a lamp and burn it?

A. I think it was about the first of March or the latter part of February.

102 X Q. Was that the first you can remember?

2194 A. Yes, sir.

103 X Q. What did you have the glass plates ground for in 1888?

A. For making these lamps.

104 X Q. Weren't some of the lamps then made?

A. Not that I recollect.

105 X Q. Don't you know that there were?

A. I believe that two were put together and burned a short time.

106 X Q. Don't you know that there were more than two?

A. I can recollect but two.

107 X Q. What do you mean by saying they burned a short time?

A. To my knowledge at least one of them burned two or three hours.

108 X Q. Didn't they all give out within two or three hours?

A. I am quite positive that they did not.

109 X Q. What makes you positive that they did not?

A. I recollect seeing the current put on one of them several days after we had abandoned working on them.

110 X Q. When did you abandon working on them?

A. I think it was in the latter part of September, 1888.

111 X Q. Is that the best of your recollection as to the date?

A. That is the best of my recollection.

112 X Q. Who put together those lamps?

A. It was done by one of our workmen, I believe, a Mr. Mayo.

113 X Q. Where is he now?

A. I do not know.

114 X Q. When did he leave your employ?

A. I believe during the first week in April.

115 X Q. Why did he leave your employ?

2195 A. He demanded higher wages, which I refused to give him, and he accordingly left.

116 X Q. What work was he employed on at the time he demanded higher wages?

A. At that time he was employed on repairs to some of our apparatus.

117 X Q. Wasn't he employed in putting together Sawyer-Man lamps for you?

A. Occasionally.

118 X Q. Wasn't he the man who put them together for you?

A. He put together most of them, not all.

119 X Q. Up to the time of his leaving, who else put up Sawyer-Man lamps?

A. Another workman of ours, named Kammer.

120 X Q. How many lamps did he put together?

A. About five or six.

121 X Q. Going back to 1888: were not Sawyer-Man lamps put together and tried in your factory, after September and before the close of the year?

A. I do not remember any just now.

122 X Q. Weren't lamps put together and burned in December of that year?

A. I don't remember it.

123 X Q. Would you swear there were not?

A. No, sir.

124 X Q. How many lamps have you yourself put together?

A. None.

125 X Q. How many of the parts of lamps have you yourself made?

A. Some of the carbons is all.

126 X Q. How many carbons did you make?

A. I cut about ten fibres and saw them baked, and treated these myself, and also treated some others.

127 X Q. How many others did you treat?

A. I treated none others for these lamps.

128 X Q. Who baked these fibres that you cut?

2196 A. Some of them were baked by John Kane, and some by Mr. Kammer.

129 X Q. How many did Kane *back?*

A. I cannot state the number, even approximately.

130 X Q. And how many did Kammer bake?

A. About six or eight, I believe.

131 X Q. Did Kammer cut any carbons?

A. No, sir, not to my knowledge.

132 X Q. That is you don't know whether he did or not?

A. I know that he had no facilities for so doing.

133 X Q. Did Kane cut any carbons?

A. No, sir.

134 X Q. Who sent you carbons for the Sawyer-Man lamps from outside?

A. Mr. Vandegrift of the Newark factory.

135 X Q. How many dozen did he send you?

A. About four dozen.

136 X Q. Do you know how many he carbonized before he sent you these four dozen?

A. I do not know.

137 X Q. Were these carbons that he sent you treated?

A. They were.

138 X Q. How many did you treat personally?

A. None of these.

139 X Q. Who did the treatment?

A. I do not know. They were all treated when I received them.

140 X Q. After Mr. Mayo left, who put the Sawyer-Man lamps together?

A. Mr. Kammer.

141 X Q. What part of the factory was this done in?

A. In the before-mentioned laboratory.

142 X Q. What part of the laboratory?

A. At the work-bench against the north wall.

143 X Q. Who is Mr. Kammer, and what was his employment by your company?

2197 A. He was engaged part of the time in repairing apparatus, the remainder of the time in working upon these lamps, being a machinist by profession.

144 X Q. Were you ever present from beginning to end while either Mr. Mayo and Mr. Kammer assembled or put together a Sawyer-Man lamp?

A. I do not recollect ever seeing this done in one continuous operation.

145 X Q. How much of the operation have you seen done?

A. I have seen every operation of making these lamps but cannot say that it was the same lamp.

146 X Q. Will you swear that you ever watched them assembling a lamp for more than an hour at a time?

A. Yes, sir.

147 X Q. What is the longest time that you have been present watching either of these men assembling a lamp?

A. I think about two or three hours.

148 X Q. What part of assembling a lamp were they doing when you first began to watch them?

A. Connecting the electrodes with the glass bottom.

149 X Q. And what was the last stage at which you saw them working?

A. I don't recollect.

150 X Q. I refer in my last question to the time you watched either of these men two or three hours, as you testify in your 147th answer. Did you so understand my last question?

A. I did.

151 X Q. How long did it take these men to connect the electrodes to the glass bottom?

A. I should say anywhere between fifteen minutes and an hour.

152 X Q. How long did it take them to assemble the lamp altogether.

A. I do not believe one ever was assembled in one continuous operation.

2198 153 X Q. Put all the operations together that you have seen separately and state what, to the best of your recollection, was the gross time occupied in assembling the parts of the lamp.

A. Provided no accidents were met with, I should say two to four hours.

154 X Q. That is your estimate of the time it would take to put together one of these lamps?

A. It is my estimate of the time required to put together one of the lamps.

155 X Q. When a carbon burnt out in one of these lamps, what had to be done to it before the lamp could be re-burned?

A. The globe required to be taken off by taking out the screws clamping the brass flanges at the bottom, the globe removed from this bottom plate, the globe and all parts cleaned, the burned-out carbon replaced with a new one, and the lamp assembled in the reverse manner.

156 X Q. All the wax and cement had to be removed, had it not?

A. That is what I meant by stating that the parts had to be cleaned.

157 X Q. And this business took two or three hours, did it not?

A. No, I should say, on an average, not more than one hour.

158 X Q. Will you swear that you ever saw it done in less than two hours and a half?

A. I do not recollect seeing it done.

159 X Q. Then you are not speaking of this from your own knowledge.

A. I am.

160 X Q. Did you ever see a lamp taken apart and put together again from end to end?

A. I do not recollect seeing this done in one continuous operation, but have seen them taken apart in less than ten minutes, and put together in less than forty minutes.

2199 170 X Q. After this the lamps were filled with nitrogen gas, were they not?

A. They were.

171 X Q. How many lamps have you personally taken apart and put together?

A. None.

172 X Q. How many lamps have you personally filled with nitrogen gas?

A. If by personally filled you mean doing all the operations unaided: none.

173 X Q. How many of the operations have you yourself performed?

A. I believe I have done each one of them at various times.

174 X Q. How many times have you taken part in the operation?

A. I do not remember.

175 X Q. Why can't you remember?

A. Because I was very busy all the time at other work, and made no special point of remembering this.

176 X Q. What else had you to do?

A. Overseeing the general manufacture of lamps, and fitting up our factory for an increase of output.

177 X Q. Who did the filling of the lamps?

A. The men before mentioned, Mayo, Kammer and Schramm, and a man named Cavenagh.

178 X Q. How many lamps did Cavenagh fill that you saw?

A. I do not recollect seeing him fill any. By filling I mean going through the entire operation.

179 X Q. How many lamps did you see him assist to fill?

A. I do not recollect.

180 X Q. How many lamps did you see Schramm fill or assist to fill?

A. I do not remember.

2200 181 X Q. How many lamps did you see Mayo fill or assist to fill?

A. I do not remember.

182 X Q. And how many lamps did you see Kammer fill or assist to fill?

A. I do not remember.

183 X Q. How long is it since you have read either of the Stillman patents?

A. About one week.

184 X Q. How came you to read it then?

A. I had no special object in reading it then, merely reading it to refresh my memory.

185 X Q. When before that had you read either of these Stillman patents?

A. I don't remember.

186 X Q. Had you ever read them since the time Mr. Garden gave them to you, until last week?

A. Yes, sir; several times.

187 X Q. Who put up your nitrogen apparatus?

A. Kammer and Schramm, with perhaps one or two helpers.

187½ X Q. How much of the work in putting up the nitrogen apparatus did you personally do?

A. In putting up one apparatus, I did perhaps three-quarters of the work.

188 X Q. Which apparatus was that?

A. It was one that we put up, I think, in August, 1888.

189 X Q. Describe that apparatus.

A. It *is* consisted of an ordinary chemical flask for generating the nitrogen, connected by means of rubber tubes with a number of Wolff or washing bottles filled with various re-agents for purifying the gas, and a rubber bag for collecting the gas at the end of the apparatus.

190 X Q. What re-agents did you use for purifying the gas?

A. As I remember the arrangement, the first bottle con-
2201 tained sulphuric acid, the next, caustic potash, then pyrogal-
late acid in solution, phosphoric anhydride, then a bottle
containing melted sodium, and finally phosphoric anhydride.

191 X Q. Who gave you directions as to putting up this apparatus?

A. Mr. Albon Man.

192 X Q. Did he come personally to see the apparatus?

A. I am not positive, but think not.

193 X Q. Didn't he give you a written description to go by?

A. I received a few notes by no means a description, which, I believe, came from Mr. Man.

194 X Q. Don't you know they came from Mr. Man?

A. This description was given me by Mr. Lewars, the treasurer of the Sawyer-Man Company, just after Mr. Man had been there. Whether it was written by Mr. Man or by Lewars at Man's dictation, I do not know.

195 X Q. But directly, or indirectly, Mr. Man had been requested to give instruction as to the apparatus, had he not?

A. I had myself asked him for some instructions.

196 X Q. And you also asked him for instruction as to putting the lamps together and the use of them, did you not?

A. Yes, sir.

197 X Q. And this was in August or September, 1888?

A. To the best of my recollection it was in August. I also received instructions from him after that date.

198 X Q. What date did you receive further instructions from Mr. Man?

A. I cannot remember the date.

199 X Q. What instructions did he give you?

A. They were mainly in regard to the necessity of exercising great care in the preparation of the parts, as to small details and the methods of working: for example, to use the proper kind of screws to use in clamping, and so forth.

2202 200 X Q. What was the trouble with the screws that they weren't quite right?

A. He cautioned me that iron screws would be preferable on account of its coefficient of expansion, and platinum could also be used with success.

201 X Q. And you tried both kinds, did you not?

A. I tried only iron and brass, finding the iron preferable.

202 X Q. What further instructions did Mr. Man give you that you can now remember?

A. The only further instructions that I can recall was as to how to proceed to grind the bottoms.

203 X Q. What did he tell you about that?

A. He told me that the proper method was to grind both the bottom plate and the bottom flange of the globe flat on a cast-iron surface plate, using fine emery and oil to grind them in this manner until the surfaces were as highly polished and smooth as it was possible to get them, and then to grind the plate and flange against each other slightly so as to insure a perfect fit.

204 X Q. I notice in the lamps you have presented in evidence, that the upper brass flange is thinner than the lower one. How did you come to use the upper flanges thinner than the lower ones?

A. I believe Mr. Man instructed me to do this, but I would have done so anyway, as the upper surface of the flange on the globe is apt to be irregular and would be easily cracked by any unequal pressure brought upon it. The giving of a thin brass plate will allow for slight inequalities in the surface.

205 X Q. As a matter of fact didn't you break quite a number of those glass flanges in the beginning because the metal plates used by you were too thick?

A. We broke quite a number of these flanges, but I do not attribute the breaking necessarily to the thickness of the brass flange, but rather to the inexperience of the workman, and the lack of sufficient packing on the top of the flange.

2203 206 X Q. As a matter of fact were the brass flanges first used by you thicker than the subsequent flanges adopted after Mr. Man's suggestions? I refer, of course to the upper flange.

A. The first ones used were thicker.

Adjourned to meet April 19th, at 10.30 a. m.

NEW YORK, *April 19th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, Esq., of counsel for complainant, and Walter K. Griffin, Esq., of counsel for defendant.

207 X Q. How many of the lamps made at the factory were finished with the metal cup and filling material shown in the patent in suit?

A. One.

208 X Q. What became of this one?

A. It burned, I think, for about three hours, and was then dismantled.

209 X Q. Why was it dismantled?

A. In order to get the parts for use in other lamps.

210 X Q. Hadn't it burned out?

A. Yes, sir.

211 X Q. Then it was taken apart because it had burned out, was it not?

A. For this reason and because we wanted the parts to use in other lamps.

212 X Q. Did you use the cup in other lamps?

A. No, sir.

213 X Q. Why didn't you use the cup in other lamps?

A. I had no instructions to do so.

214 X Q. You described a nitrogen apparatus used by you in 1888 as being one apparatus you used for nitrogen. When did you use a second apparatus?

2204 A. I think the second apparatus was set up in the first part of February, 1889.

215 X Q. Who set up that apparatus?

A. Mr. Kammer.

216 X Q. Was this the apparatus you described as being the Stillman apparatus.

A. Yes, sir.

217 X Q. And this apparatus, I understand, continued to be used until the end of your experiments?

A. It was modified slightly, and the modified apparatus was used.

218 X Q. When was this modification made?

A. I think about a week after this second apparatus was set up.

219 X Q. You spoke yesterday of lamps being tried on the air pumps and found to leak. To what experiments did you refer?

A. We exhausted these lamps on the air pump in connection with a vacuum g*ua*ge, shut off the air pump, and observed whether or not the vacuum g*ua*ge fell.

220 X Q. As I understand it these lamps were filled with gas and all ready to be burned, were they not?

A. They were.

221 X Q. And you tested them, and when you found them unsatisfactory, took them apart, did you not?

A. Yes, sir.

222 X Q. Turning to the seven lamps mentioned by you in your 4th answer, did you make any one of those seven lamps?

A. Not with my own hands. They were all made under my personal direction.

223 X Q. You mean by that, that you as superintendent gave directions to have lamps made and they were made?

A. Yes, sir.

224 X Q. Who made those lamps?

A. The various workmen under me. Some of the work was done by outside parties.

2205 225 X Q. You stated that radiators or conductors were sent from Pittsburgh to you. How many dozen were sent to you from Pittsburgh?

A. I think it was two dozen.

226 X Q. Wasn't it a great many more than that?

A. No, sir.

227 X Q. Would you swear that there were not five dozen sent?

A. No, I can't.

228 X Q. In other words you are not certain of the number?

A. I am not certain.

229 X Q. How many sets of parts for the lamps were sent to you from Newark?

A. I think it was 24.

230 X Q. You state in your 4th answer that lamp No. 1 with a bamboo carbon, burned for 240 hours at 22 candle power. Is that correct?

A. To the best of my knowledge and belief it is.

231 X Q. Where does your belief come in on this matter?

A. I believe that the workmen spoke truly when they so informed me.

232 X Q. Did you ever see that lamp burning yourself?

A. Yes, sir.

233 X Q. Did you ever test its candle power yourself?

A. No, sir.

234 X Q. Was its candle power ever tested or any electrical measurements taken before the lamp was first burned regularly?

A. Not until after it had been burned some time.

235 X Q. And as I understand you, you did not ascertain before that lamp was burned the electrical conditions as to voltage and current under which it was to be burned?

A. No, sir.

236 X Q. Did you do that with any single lamp at any time before regularly burning it?

2206 A. It may possibly have been done. I did not do it.

237 X Q. And you don't know and you never heard of anybody else doing it, do you?

A. No, sir.

238 X Q. In other words you put up the lamps at random without any knowledge of the electrical conditions under which they were to be burned to give a standard candle power?

A. They were not put at random. They were put in circuit, and sufficient current sent through them to bring the carbon to what we judged to be a proper degree of incandescence.

239 X Q. But this current you did not measure?

A. No, sir.

240 X Q. In making lamps for the market, do you not send out lamps with standard *guages* as to the strength of current required to bring them to incandescence for the use of your customers?

A. We do.

241 X Q. And each lamp is tested and marked as to its electrical conditions before it is sent out, is it not?

A. Not as to all its electrical conditions.

242 X Q. Do you not test them so as to find the electrical current or amount of pressure necessary to give the candle power which they are intended to be used at?

A. We run them up to the standard candle power, ascertain the voltage, and mark this and the candle power on the lamp.

243 X Q. You say your factory sometimes turned out 3,000 lamps a day. What are the different electrical pressures required by these lamps when working at normal incandescence? Between what limits will they run?

A. The manufactured lamps between the limits of about four volts up to 128 volts.

244 X Q. What would be the effect of sending out lamps to the public without making these tests, and indicating upon the lamps the conditions of use?

2207 A. Disastrous.

245 X Q. Simply ruin the business, would it not?

A. Not necessarily.

246 X Q. And these Sawyer-Man lamps were not so tested by you?

A. Not before being run.

247 X Q. How many tests of the candle power of these lamps did you personally make?

A. None.

248 X Q. How many did you see made?

A. None.

249 X Q. What date do you understand any tests were made?

A. As nearly as I can remember, about the 1st of April.

250 X Q. How long had you been informed that lamp No. 1 had then burned?

A. I do not remember.

251 X Q. How long after the test was this lamp burned?

A. I can't state positively, but believe about 100 hours.

252 X Q. Will you swear that lamp No. 1 burned one hour after the test?

A. Yes, sir.

253 X Q. Will you swear that it burned two hours after the test?

A. Yes, sir.

254 X Q. What day did lamp No. 1 fracture its carbon?

A. I will require to look at the lamp; it is marked on the lamp. The record is March 20th.

255 X Q. Do you mean that the lamp burned out March 20th?

A. Yes, sir.

256 X Q. What does the date March 5th mean which is marked above March 20th.

A. That is the date of its being started on the test.

2208 207 X Q. Then I understand you that the lamp broke down March 20th, and was tested April 5th, as you understand the record written on this lamp?

A. No, sir. It was first burned April 5th.

258 X Q. That is when it started to burn, and it burned out or broke down March 20th?

A. Yes, as I understand it.

259 X Q. Was April 5th the day the tests were made as to candle power?

A. I believe it was tested latter than that.

260 X Q. Will you swear that you ever made or that any one ever made any tests of the Sawyer-Man lamps as to their candle power, except on April 5th?

A. No, sir.

261 X Q. Wasn't that the day that the only test was made that was ever made of these lamps?

A. I don't know.

262 X Q. Which month comes first in the year: March or April?

A. March.

263 X Q. How do you explain then that the lamp, according to

your testimony just now, was first burned April 5th, and burned out, or had its carbon broken March 20th.

A. I should have stated the dates April 5th, and March 20th, in the reverse order from what I did.

264 X Q. From what memoranda did you get the statement of candle power which you made in your direct testimony?

A. Memoranda furnished me by the workmen and from the marking on the lamp.

265 X Q. What is the date of the memoranda furnished you by the workmen?

A. April 11th.

266 X Q. And what date was the test, was it not April 5th?

A. I do not know.

2209 267 X Q. And this memoranda which was given you was dated six days after the lamp broke, according to your testimony?

A. Yes, sir.

268 X Q. Now again I ask you whether you will swear as a matter of fact, that lamp No. 1, burned more than a single hour after the test was made of its candle power?

A. I will.

269 X Q. How do you know that it burned more than a single hour?

A. From the fact that I saw it burning after the marking was on the lamp and after the report had been made by me that the lamps were tested.

270 X Q. You stated you were not present at the tests, have you not?

A. I have.

271 X Q. Therefore of your own knowledge you know nothing of the candle power arrived at by the means of that test, or of the electrical conditions of that test, is that not so?

A. That is true.

272 X Q. And you don't know the time of that test?

A. No, sir.

273 X Q. Nor anything about it, except what somebody has told you?

A. That is all.

274 X Q. When were lamps Nos. 2 and 3 and Nos. 5 and 7 tested, as reported to you? Was it not at the same time as lamp No 1?

A. I believe it was.

275 X Q. How long does it take to make a test of the candle power of a lamp? I mean how long is the lamp subjected to the current for the purposes of the test?

A. Generally only long enough to read the instruments.

276 X Q. How long does that take; half a minute, or a minute, or how long?

2210 A. From a quarter of a minute to three minutes.

277 X Q. And these electrical measurements as to voltage and as to the number of amperes in the current and the candle power on such of these seven lamps as were tested were derived

from such a test, as far as you know, lasting possibly from a quarter of a minute to a minute.

A. They were derived from such a test; but the test in this case must have taken at least two minutes.

278 X Q. Were you there to see the test made?

A. No, sir.

279 X Q. Who did you understand carried out the test?

A. F. E. Cavenagh.

280 X Q. Who else, if anybody?

A. I believe Mr. Kammer was present when the test was made.

281 X Q. Was Mr. Cavenagh the man who burned the lamps regularly?

A. Yes, sir; Cavenagh and Kammer conjointly.

282 X Q. Wasn't Mr. Cavenagh the man employed in the test-room regularly?

A. Not regularly.

283 X Q. You stated in your 5th answer the efficiency of the Sawyer-Man lamp. Was not that efficiency calculated from this test, lasting not more than two minutes, of the lamps just referred to by you?

A. No, sir; I only estimated their efficiency.

284 X Q. When did you estimate their efficiency?

A. At various times, judging by the degree of incandescence of the carbon, and the amount of current flowing through them.

285 X Q. How did you measure the amount of current flowing through them? Did you ever do it?

A. I never measured it.

2211 286 X Q. Going back to lamp No. 1, you testified that in addition to yourself and Mr. Robertson, Messrs. Curtis and Kerr, the attorneys for the consolidated company, and Mr. Shallenberger, of the Pittsburgh factory, had been up to your factory either to see or to talk about the lamps. Am I right?

A. Yes, sir.

287 X Q. When did Mr. Shalleberger first call at the factory?

A. I don't remember.

288 X Q. Did you or your men have any lamps to show him?

A. We had the parts. Whether we had any completed lamps or not, I don't remember.

289 X Q. Did he ever see any of your lamps burning?

A. Yes, sir.

290 X Q. When?

A. I can't state the date.

291 X Q. How many did he see?

A. We had at least three burning.

292 X Q. Are those three any of the seven you have presented in your testimony?

A. No. 1 was certainly burning, and I think, two others that are presented.

293 X Q. What candle power were they burning at?

A. Certainly over 16 candle power. The exact candle power I do not know.

294 X Q. Will you swear they were over three or four candle power?

A. Yes, sir.

295 X Q. Don't you know that Mr. Shallenberger told you to increase the candle power because what he saw was no test?

A. He directed me to increase the candle power; but I do not remember his stating that reason.

296 X Q. What other reason did he give you, or do you understand was given.

A. I don't remember any.

2212 297 X Q. Wasn't the only reason because the candle power at which you had those lamps burning was not a fair test?

A. I do not know his reasons.

298 X Q. Don't you know the candle power was not a fair test?

A. No, sir, I do not.

299 X Q. What possible reason then had you for raising the candle power of the lamps?

A. The reason was that we might give them a more severe test.

300 X Q. And did you give them that more severe test?

A. For about one day.

301 X Q. And how many of the lamps broke down under that more severe test in that one day?

A. I believe one broke.

302 X Q. Will you swear there were not three broke?

A. Yes, sir.

303 X Q. Didn't one break through the cracking of the glass globe?

A. I did not know of it, if it did.

304 X Q. And you can't say whether it did or not?

A. No, sir.

305 X Q. And didn't another burn out within nine hours after the more severe test had begun to be applied to it?

A. I believe so.

306 X Q. And didn't a third lamp burn out within six or nine hours afterwards, under that more severe test?

A. I know nothing of the burning out of any except the one lamp.

307 X Q. And you don't know whether more burned out or not?

A. I know that one more may have burned out.

308 X Q. You recollect that now?

A. No, sir.

309 X Q. What is your recollection about that other lamp that may have burned out?

2213 A. I remember seeing four or five lamps burning during this test, and that next day after the test discontinued there were certainly not three of the lamps missing.

310 X Q. And you gave up this more severe test within a day after beginning it, did you not?

A. The lamps were not run after this quite as high as Mr. Shallenberger had left them.

311 X Q. And what was your reason for putting down the degree of incandescence again?

A. I considered it an unfair test, the lamps being at an abnormal brilliancy.

312 X Q. Didn't you find out that the lamps would not stand that test?

A. No, sir.

313 X Q. Weren't you told that the lamps would not stand that test, and didn't you order them to be put down again?

A. I was so told, and gave such orders.

314 X Q. Who told you so?

A. Mr. Kammer, and I think Mr. Robertson.

315 X Q. What did Mr. Kammer say to you and what did Mr. Robertson say to you?

A. Kammer simply told me the lamps gave a very brilliant light and probably would not stand it long. I don't remember what Mr. Robertson said.

316 X Q. Didn't you understand at the beginning of your experiments that your object was to be to get these lamps to burn as long as possible?

A. No, sir.

317 X Q. You didn't understand that?

A. No, sir.

318 X Q. Wasn't that your effort?

A. My effort was to make them burn as long as possible with a fair degree of economy.

319 X Q. And you never measured the amount of current that was consumed or employed?

A. Only during the test I mentioned before.

2214 320 X Q. And as to the circumstances of that you personally know nothing?

A. That is true.

321 X Q. In your seventh answer you state that you have tried the use of nitrogen in an ordinary bulb lamp. When did you try this?

A. I think I first tried it about the first of 1887, and later, during last March.

322 X Q. What experiments did you try in March?

A. Tried it on two separate sets of lamps, one of which lamps is offered in evidence.

323 X Q. How many lamps were in the first set?

A. I think three.

324 X Q. Were there not four?

A. I don't remember.

325 X Q. What percentage of nitrogen did you put in this first set of lamps?

A. Varying from, I should say, 60 per cent. to about 2 per cent.

326 X Q. Was that on the first set?

A. Yes, sir.

327 X Q. How long did those lamps burn?

A. My recollection of it is that one was broken in finishing, and the two others were burned out at about the end of 60 hours by too high an electro-motive force.

328 X Q. These were ordinary commercial lamps with the exception of the use of nitrogen gas, were they not?

A. Yes, sir.

329 X Q. That is to say, they did not differ in any respects from the ordinary incandescent lamps sold by your company to the public except for the presence of nitrogen instead of an air vacuum.

A. That was the case.

330 X Q. How many lamps did you fill with nitrogen in the second set?

A. Three.

331 X Q. Wasn't it four?

2215 A. No, sir.

332 X Q. How do you know it wasn't four?

A. Because it was done but a short time ago. I was personally present, marked every lamp and kept a record of it.

333 X Q. Where is your record?

A. I have it with me.

334 X Q. What was the percentage of nitrogen in those lamps?

A. In lamp No. 1 estimated it about $\frac{3}{16}$th inch pressure. In lamp No. 2, estimated $\frac{1}{2}$ inch pressure. In lamp No. 3, estimated 20 inches pressure.

335 X Q. What was the life of these lamps Nos. 1, 2 and 3 respectively?

A. Lamp No. 1 ran 126 hours, when it was taken down to be filed as evidence; it was then apparently perfect. Lamp No. 2, the bulb was broken in finishing. Lamp No. 3 burned out at the end of 80 hours' run.

336 X Q. So that the lamp that had least nitrogen burned longest?

A. Of the two tested in this case it did.

337 X Q. And those tested in the previous tests lasted about 60 hours, according to your recollection?

A. Yes, sir.

Adjourned to meet at 2 p. m.

Resumed at 2 p. m.

338 X Q. At the same time that you filled these three lamps with varying quantities of nitrogen, didn't you pump out a fourth lamp to the ordinary commercial air vacuum?

A. I did.

339 X Q. Did you have these four lamps tested as to their electrical condition?

A. I did.

340 X Q. Were they tested before they were burned regularly?

A. Yes, sir.

2216 341 X Q. Give the results of that test in the voltage and amperes for four lamps at the candle power at which you tested them?

A. I have not the record of that test.

342 X Q. Didn't you have a copy of that record?

A. I had a copy and mislaid it. I can from memory give the result of two of these tests. Lamp No. 0 commercial vacuum, 32 candles, 50½ volts, 2 amperes. Lamp No. 3, 20 inches nitrogen, 32 candles, 57 volts, and about 2.3 amperes. Lamp No. 1 about 52 volts, 32 candles, 1.15 amperes.

343 X Q. Whom were these tests made by. Were they not made by Mr. Cavenagh?

A. They were.

344 X Q. Are not the aggregate figures for those four lamps as follows: commercial vacuum lamp, volts 50.5, amperes 1.98. Lamp No. 1, volts 55, amperes 2.11. Lamp No. 2, volts 55.5; amperes 2.24. Lamp No. 3, volts 57.5; amperes 2.32? All tested March 30th at 32 candle power.

A. As I remember it, this is correct, with the exception of the commercial vacuum lamp, which certainly did not take less than 1.9 amperes. I misunderstood the question as read to me, and will omit the exception made.

345 X Q. Upon these figures what was the difference in the resistance of the lamps between the commercial lamp and lamp No. 3, with the nitrogen admitted at a pressure of about 20 inches as tested at your factory?

A. The resistance of these lamps, to my knowledge was not measured.

346 X Q. Being given the volts and the amperes can you not calculate the resistance?

A. I can.

347 X Q. Will you please do so for these two lamps?

A. The resistance of the commercial vacuum lamp I make 15½ ohms hot; lamp No. 3, 24.6 ohms.

348 X Q. Similarly will you please calculate the watts for the two lamps?

A. I make the watts, taken by these two lamps respectively, 99.9 and 133.4.

2217 349 X Q. And this 133.4 for the lamp filled with nitrogen was for a vacuum of about two-thirds, or more precisely $\frac{20}{32}$nds? Is that not so?

A. No, sir. It was for a vacuum of about one-third.

350 X Q. Have you made any test of lamps filled with nitrogen at the normal pressure?

A. No, sir.

351 X Q. What was the life of the commercial lamp No. 0 in the second series?

A. It has been burned for 126 hours, and is still apparently perfect.

352 X Q. Burned alongside No. 1 in the same circuit?

A. There was a small resistance introduced into the circuit of

No. 0, in order to get the same apparent candle power from the two lamps.

353 X Q. It was a 50-volt current was it not?

A. About a 54-volt current.

354 X Q. Did you measure the current?

A. I measured the current of that circuit frequently.

355 X Q. How did you measure it?

A. By means of a Cardew volt-meter.

356 X Q. Did you burn the other lamps of the same series on the same circuit continuously?

A. The other one of the series, No. 3, was burned on the same circuit.

357 X Q. And did you similarly introduce resistances for that lamp?

A. No, sir.

358 X Q. Why not?

A. Because it did not require it.

359 X Q. In other words you kept up the current at about the voltage required to keep that lamp at a standard 32-candle-power incandescence?

A. About that.

360 X Q. As I understand, you took pains then to subject these three lamps to a careful test, the lamps being preserved at normal incandescence of 32 candles?

2218 A. That was my intention.

361 X Q. And you tested the four lamps of this series before burning for this purpose, did you not?

A. Yes, sir.

362 X Q. And kept them under the requisite conditions as to standard incandescence until the end of the experiment?

A. As near the standard as we could.

363 X Q. You stated that Mr. Kammer worked on the nitrogen apparatus. When was he first employed by you on the nitrogen apparatus?

A. I think it was about the latter part of August.

364 X Q. Did he not enter the service of your company in August?

A. I don't remember; but my impression is that he came to us before that.

365 X Q. Who assisted you in putting up your first nitrogen apparatus?

A. Mr. Cavenagh and Schramm.

366 X Q. This was in August, 1888, was it not?

A. As I remember it, yes.

377 X Q. Didn't you ask Mr. Kammer in December, 1888, what he knew about nitrogen, and give him the Stillman patents, directing him to rig up a nitrogen apparatus?

A. As to the date, I don't remember. I did give Kammer these patents, and told him to go ahead on them using the apparatus which we then had.

388 X Q. And didn't he then fill some lamps; and weren't they burned and shown to you and Mr. Robertson?

A. That is the case.

389 X Q. And did they not last about 2, 3 or 4 hours?

A. My recollection of it is that some of them burned out in two or three hours; but that at least one was preserved for several days.

390 X Q. Don't you remember now that this was in December, 1888?

A. I am inclined to think you are right about that.

2219 391 X Q. And this one lamp that was preserved, was it not burned for about an hour and a half before Mr. Kammer was directed to stop burning it and preserve it?

A. I have no recollection of that.

392 X Q. You stated in your direct testimony that you made the lamps according to the directions in the patent in suit. Is there any substantial difference between the size of any of the globes you used and the size of the globe in figure 4 and figure 3 of the drawing?

A. To my eye there is very little difference in the size.

393 X Q. I see you have a *guage*, kindly measure and say what is the exact difference between the outside measurement of the globe shown in figures 3 and 4 of the patent in suit and the globes actually used by you in your experiments.

A. At the top of the globe they are practically the same size; the bottom of the globe I have measured is about $\frac{3}{16}$ larger than that shown in the patent.

394 X Q. Is there any difference in the number of corrugations in the radiators or conductors in the lamps as used by you, as compared with the radiator or conductor shown in figure 2 of the patent?

A. The number of corrugations in the radiators used by us varied somewhat; but they are approximately the same in number as those shown in the patent.

395 X Q. Of the four before you three have the same number of corrugations as the one shown in the patent; to wit, 21 corrugations?

A. As closely as I can count them they have.

396 X Q. Is there any material difference in the operation of the lamps whether the globes are a little larger or smaller than those shown in figures 3 and 4 of the patent in suit, or whether the corrugations are more or less than there shown?

A. I have noticed no such difference.

397 X Q. And in manufacturing these lamps you would not consider the size of the globe or the exact number of corrugations as material, would you?

2220 A. Provided the various parts were adapted to each other, no.

398 X Q. Where did the upper brass circular discs with their insulating strips of mica come from?

A. A few were made by us, most of them coming from the United States factory in Newark.

399 X Q. When did you first adopt the mica insulation?

A. We have used it from the start.

400 X Q. Why in making these lamps did you, or the workmen of your company, reverse the position of the radiators or conductors as compared with the position shown in the patent?

A. I never noticed the difference.

401 X Q. What is the effect of so reversing those radiators or conductors upon the distance between the standards or clamps between which the incandescent carbon is fastened, as compared with what the similar distance would be with globes of the same diameter were the radiators fastened as shown in the patent?

A. It would apparently bring the clamps closer together.

402 X Q. You mean that the method shown in the patent would do this, do you not?

A. I do.

403 X Q. What is then the resultant difference in the length of the incandescent carbon because of the method adopted by you in comparison with the method shown in the patent? Is it not to increase the length of the conductor or incandescent carbon?

A. It would increase the length slightly.

404 X Q. Is not the distance between the points of attachment of the carbons in your lamp in globes of the same size more than twice that shown in figures 3 and four of the patent?

A. I should say, not quite twice as much.

405 X Q. You mean judging by measur-ments through the glass, do you not?

2221 A. I do.

406 X Q. Assuming the semicircular carbon as shown in the patent, and the paper carbon lamp No. 2, produced by you in your direct testimony, is not the effect of the arrang-ment of the corrugated radiators to give an incandescent carbon of twice the length substantially of the carbon shown in the patent for a globe of the same size?

A. Taking the exact arrangement of the radiators as in the lamps I have produced, it is; but this is not necessarily due to a reversal of the position of the radiators.

407 X Q. It is due to the fact that the holders or clamps for the carbon are twice as far apart in the lamps you produced as in the lamps with the same sized globes shown in the patent. Is that not so?

A. It is.

408 X Q. Assuming carbons of the same cross-section, what is the variation in the resistance of the two carbons by reason of this increased distance between the clamps?

A. The resistance of the carbon used in our lamps would be considerably greater.

409 X Q. How much greater, assuming the carbons to be twice the length?

A. Assuming the carbon used in our lamps to be twice the length of the other, its resistance would be twice as great.

410 X Q. And the carbons in your lamps as presented by you in your direct testimony, are at least twice the length, are they not?

A. Some of them are at least twice the length; but some, I think are not quite twice the length.

411 X Q. Take the bamboo carbon lamp, No. 1, isn't that substantially three times the length?

A. Yes, sir.

412 X Q. And how does the cross-section of the bamboo filament in your lamp No. 1 compare with the cross-section of the carbon arch shown in figures 3 and 4, having the same size globe in the patent?

2222 A. The carbon in our lamp is considerably the smaller in cross-section.

413 X Q. Does not that give a carbon arch in your lamp a much higher resistance?

A. Certainly.

414 X Q. The resistance varies inversely as the square of the diameter, does it not, for the same material?

A. Provided the carbons have been similarly treated it does substantially.

415 X Q. Is not the bamboo filament in your bamboo lamp No. 1 at least four or five times less in cross-section than the carbon arch shown in figures 3 and 4 of the patent for globes of the same size?

A. No, sir. I think not.

416 X Q. Looking through the glass, what is your present approximation as to the difference?

A. I would estimate the carbon shown in the patent to be about two and one-half times the size of the carbon in lamp No. 1.

417 X Q. So that the bamboo filament in your lamp No. 1 would by reason of its length have three times the resistance and by reason of its diminished cross-section six and a quarter times the resistance or altogether 18 and ¾ times the resistance of an identical carbon if made of the size shown in figures 3 and 4 of the patent for a globe of the same size, assuming your measurements to be substantially accurate?

A. That is my calculation.

418 X Q. So that if you have made and used a lamp exactly as shown in the patent in suit for a globe of the same size as used by you, you would have had a resistance 18¾ times less than that actually arrived at in your lamp No. 1. Is that not so?

A. Apparently, yes, sir.

419 X Q. From your electrical experience that is so, is it not?

A. Substantially, yes.

2223 420 X Q. Turning to the figures given by you to this lamp in your 4th answer, namely, volts 23, amperes 12, does not that give very close on 2 ohms for the resistance of that lamp No. 1 under the conditions, whatever they may have been of the test?

A. Yes, sir.

421 X Q. And if the carbon had been made of the same material and of the size shown in figures 3 and 4 of the patent for a globe of the same size, the resistance would have been approximately one-ninth of an ohm, would it not?

A. Yes, sir.

422 X Q. What would be the difference between the heat developed at the clamps, between the filament used in your lamp and that shown in the patent in suit, other circumstances being equal?

A. The heat would be greater with the carbon of the size shown in the patent.

423 X Q. And if the resistance of the clamps was the same there would be 18¾ times as much heat developed at the clamps in the patent in suit as in the bamboo filament actually used by you?

A. I do not know.

424 X Q. What is the reason of your doubt?

A. Any statement as to what should occur in the case stated would be a mere guess on my part.

425 X Q. If you have two carbon clamps of the same resistance, and in one lamp the filament has 18¾ times the resistance of the filament in the other, what is the difference in the heat developed at the clamps by the same candle power?

A. I positively don't know.

426 X Q. Doesn't the heat at the clamps vary as the square of the current, the resistance of the clamps being assumed the same?

A. I don't know.

427 X Q. But your knowledge tells you that the heating
2224 at the clamps would be much greater with a bamboo carbon
of the size shown in the patent in suit figures 3 and 4, than
is the case with your bamboo filament No. 1, contained in a globe
of the same size?

A. Yes, sir.

428 X Q. And lamp No. 1 failed because the carbon burned out at the clamps, did it not?

A. The failure of the lamp was caused by imperfect contact between the carbon and the clamp.

429 X Q. And that developed extra heat at the clamp, did it not?

A. Yes, sir.

430 X Q. And this extra heat caused, as you imagine by imperfect contact burned out the carbon at the clamp, did it not?

A. Yes, sir.

431 X Q. And if a similar defect of imperfect contact had existed with a carbon of the size shown in figures 3 and 4 of the patent in suit there would have been a much greater tendency for that carbon to have burned out at the clamps, than existed with your lamp No. 1? Is that not so?

A. I think not.

432 X Q. Why not?

A. Because I think that with a carbon of the size shown in the patent, the heating of it up by the passage of the current would swell the size of the carbon and improve the contact, also in this carbon it has a much larger surface of contact with the clamp.

433 X Q. Isn't that all humbug?

A. It is not humbug, I have seen instances of this.

434 X Q. Does not your answer imply much greater current?

A. I don't understand the question.

435 X Q. Which is the easier to make: a half-ampere lamp, or a 20-ampere lamp of the same candle power?

A. I think there is no more difficulty in making one than in making the other.

436 X Q. In which lamp is there the greatest tendency to heating at the clamps?

2225 A. In the 20-ampere lamp.

437 X Q. Isn't the tendency to heating at the clamps, the resistance of the clamps being the same, or in other words, the clamps being identical, 1,600 times as much in a 20-ampere lamp as in a half-ampere lamp?

A. I don't know.

438 X Q. In other words you don't know the law or rule governing the production of heat of a given current through a given resistance? Is that so?

A. That is true.

439 X Q. And you don't know that it varies with the square of the current?

A. I did not know it.

440 X Q. How did you calculate the watts in your 5th answer on direct in giving the voltage and amperes of current?

A. By taking the product of the volts and amperes.

441 X Q. Going back to the lamps that Mr. Kammer made in 1888 for you, you saw them burning, did you not?

A. I saw the Sawyer-Man lamps made in 1888 burning.

442 X Q. I mean the lamps that burned 2, 3 or 4 hours. You saw those?

A. Yes, sir.

443 X Q. Mr. Kammer told you how long they were burning?

A. I believe so.

444 X Q. Didn't you tell him the Sawyer Company ought to give you and him a thousand dollars for making those lamps burn as long as that?

A. I think not. I have no recollection of saying it.

445 X Q. Please look at the paper-carbon lamp No. 6 referred to by you in your direct testimony, and at the paper-carbon arch. What does the condition of that carbon in that lamp indicate to you as to the uniformity of incandescence throughout that carbon when burning?

2226 A. It was probably of greater incandescence at its outside circumference.

446 X Q. Is it not just the opposite?

A. I think its condition would indicate what I have stated.

447 X Q. What in its condition indicates to you that the current chose the longer instead of the shorter path in that paper carbon?

A. The carbon appears to be in better condition on the inner circumference.

448 X Q. You mean by that there are more signs of treatment, of artificial treatment, of carbon on the inside diameter than on the outside, do you not?

A. I meant that there were more signs of disintegration on the outside?

449 X Q. Where do you find most signs of deposited carbon, on the inside or outside diameter?

A. On the inside diameter.

450 X Q. Could not that be accounted for by the fact that there was a greater incandescence during the period of deposition on the inside diameter than on the outside?

A. Yes, sir.

451 X Q. And if the paper were originally uniform in resistance, you would expect the current to produce greater incandescence on the inside than on the outside diameter.

A. I would expect the current to produce greater incandescence on the inside circumference.

451 X Q. And this increased incandescence on the inner circumference would cause greater deposition of artificial carbon during treatment on the inner than on the outer circumference, would it not?

A. Yes, sir.

452 X Q. And the increased deposition of carbon on the inner circumference would lower the resistance of the inner circumference as compared with the outer circumference, would it not?

A. Yes, sir.

2227 453 X Q. And this reduction in resistance would again tend in actual burning of the lamp to cause increased incandescence on the inner circumference as compared with the outer, would it not?

A. Yes, sir.

454 X Q. And the difference between the lengths of the paths for the current would be proportionately greater in an arc of small circumference as shown in figures 3 and 4 of the patent in suit as compared with the arc or arch employed by you in your lamps. Is that not so?

A. Yes.

Adjourned to meet April 20th, at 10 a. m.

NEW YORK, *April 20th*, 1889.

Met pursuant to adjournment.

Present: Thomas B. Kerr, Esq., of counsel for complainant, and Walter K. Griffin, Esq., of counsel for defendant.

455 X Q. How long did it take to fill the lamps with nitrogen?

A. The entire process of washing and filling the lamps with nitrogen, occupied, I believe, about six hours.

456 X Q. And during this six hours nitrogen was allowed to flow through the lamps while the carbon was kept more or less incandescent and before you ventured to seal up the lamps. Is that not so?

A. Yes, sir.

457 X Q. Did you ever try any lamps without letting the nitrogen pass through for five, six or seven hours?

A. I do not know of any such being tried.

458 X Q. And this process of passing through nitrogen six hours was to insure the cleansing of the interior of the lamp from atmospheric air, was it not?

A. For that and also for the purpose of purifying the nitrogen.

2228 459 X Q. The lamps were so burned on the gas bags containing the supply of nitrogen, were they not?

A. Yes, sir.

460 X Q. Can you swear that after beginning your experiments in February or March, that you have not had at least as many as 80 lamps finished and burned apart from the lamps tested on the air pumps?

A. I cannot swear as to the number; but am quite positive that no such number was ever made by us.

461 X Q. I don't mean separate lamps; but lamps refilled and retested?

A. I so understood the question.

462 X Q. How many lamps were reported to you to have been tested in the tests made early in April as to the candle power? Was it not five lamps?

A. I believe that was the number.

463 X Q. Do you of your own personal knowledge know of any of the conditions under which any of the lamps were burned, except during such time as you happened to be present in the room where they were burned?

A. Of my own personal knowledge, no.

Redirect examination by Mr. KERR:

464 R. D. Q. Please state whether Kammer is still working for you, and if not, state the circumstances of his leaving you, when it occurred, and the causes, so far as you know.

A. Kammer is not working for us now. I believe it was the 13th of April that he left. I had told him on the afternoon of the day before, that Dr. Stillman would be up the next morning for the purpose of examining our nitrogen apparatus, and of using it in filling some of the Sawyer-Man lamps, and directed Kammer to have the apparatus in complete working order. He was apparently greatly displeased at this information, leaving me instantly without saying a word. The next morning I told him that I would send Cavenagh up to examine the lamps he then had burning and inspect their condition. He was again greatly displeased at this, muttering to himself complaints which I did not understand, and again went off apparently about some work. Cavenagh came to me shortly after saying that Kammer was wild about something and that I had better go and see him. Cavenagh also stated that he had been into the laboratory, in accordance with my instructions; that Kammer had ordered him out; that he remonstrated with Kammer, saying that Mr. Packard had instructed him to go there. Kammer muttered with several oaths 2229 that he would not be interfered with, and immediately commenced to pack up his belongings. As soon as I heard this I went back to the laboratory and found Mr. Robertson and Kammer there, Mr. Robertson was apparently questioning Kammer as to his reasons for leaving in this manner. All that I could catch of Kammer's answers were his mutterings about not being interfered with. He was greatly excited, his face was flushed, he could hardly utter an articulate word, his voice trembling with anger. He immediately left, taking with him a couple of bundles. I found immediately after he had gone that part of the nitrogen apparatus, the sodium bottle, which I had seen working perfectly the evening before, was broken and could not be used. This same bottle had been in use for about a week, working perfectly all the time, and should not have required any further adjustment or arrangement for the experiment we had then in view, and if not interfered with I do not believe it could have been broken.

465 R. D. Q. Please state whether Dr. Stillman came, and whether he was able to use the nitrogen apparatus.

A. Dr. Stillman came at about 11 o'clock that morning, but was unable to use the apparatus in its dismantled condition.

466 R. D. Q. Please state how closely you watched the construction, filling and testing of the Sawyer-Man lamps which you testified to in your present examination.

A. I watched all these operations as closely as my regular duties would allow, observing each operation minutely, 2230 being in and out of the laboratory several times a day, and constantly receiving reports from there from all of the workmen there employed, and from Mr. Robertson.

467 R. D. Q. Was there any difference in the way you conducted these tests from that in which your ordinary tests as to your regular commercial manufacture of lamps is carried on?

A. It was done in precisely the same manner, I being unable by press of work to personally do the work on these lamps, or attend to their testing.

468 R. D. Q. Was there any difference in the way in which you conducted these tests and this manufacture from the way in which you conduct the manufacture of ordinary commercial lamps, and the tests and measurements upon which you settle the questions of cost, selling price, labor, and other things which enter into the estimates upon which your commercial business is conducted?

A. My relation to these tests in this manufacture was precisely the same as my relation to the ordinary commercial manufacture, as stated in the question. This work was regarded as experimental, the lamps not being intended for commercial use, and the tests were accordingly not conducted in the regular manner, that is, the regular series of tests which our commercial lamps go through.

469 R. D. Q. In your ordinary commercial tests upon which you base your estimates, do you conduct them personally or do you assign the various things to be tested to others, and receive their reports of the same, adopting them as your own?

A. In our commercial work, I, of necessity, leave all this testing to be done by others, and, of course, adopt their reports as my own, as often as possible checking the tests personally when I have any reason to think that they are not properly made.

2231 470 R. D. Q. Did you do any differently from that in connection with the construction, filling and testing of the lamps to which you have testified?

A. I acted in precisely the same manner, assuring myself that the instruments and apparatus were in proper order.

471 R. D. Q. Have you any reason to doubt that the reports which you received and to which you have testified, were exactly correct?

A. I have no reason to doubt.

472 R. D. Q. From your daily inspection of the tests of these lamps do you, or not, believe that those reports were exactly true?

A. I believe they were perfectly true.

473 R. D. Q. State whether or not you believe the construction, filling and tests of the lamps to which you have testified were full, fair and trustworthy.

A. I do so believe.

474 R. D. Q. Was it your custom to have such conversations with Kammer as that one which you were asked about relating to a thousand dollars?

A. It was not my custom.

Recross-examination by Mr. GRIFFIN:

475 R. X Q. Were not these lamps burned in a separate room and not in the general laboratory?

A. They were.

476 R. X Q. Who was employed in that room?

A. Kammer, Cavenagh, Schramm, and various workmen as we occasionally had work for them. I do not mean to say that all the parties mentioned were employed there regularly.

477 R. X Q. While these experiments were going on was not Mr. Kammer employed there regularly?

A. No, sir; what machine work he had to do was not done in this room.

478 R. X Q. Wasn't that his regular room or laboratory?

2232 A. For the purpose of this lamp work only.

479 R. X Q. What did you pay Mr. Kammer a week?

A. $23 a week was his salary.

480 R. X Q. And with overtime or extras did not his pay run from $30 to $36 a week, during the period of these experiments?

A. No, sir, it was only during the last two or three weeks, possibly four weeks, that he received overtime.

481 R. X Q. How many hours since the beginning of these experiments has he devoted to other work than these experiments?

A. I believe on an average about two or three hours a day.

482 R. X Q. And this work was done in the room where the lamps were burned, was it not?

A. Yes, sir.

483 R. X Q. Outside of the written memoranda of the test of the five lamps early in April, was any memorandum of these tests given ou?

A. No, sir.

484 R. X Q. Was it reported to you that when lamp No. 1 was raised to the degree of incandescence at which it was usually burned and Mr. Cavenagh made the tests upon the photometer, that the result was four candles?

(The question is objected to as a mere rehash of the cross-examination, and is immaterial, and attention is called to the course of the defendant's counsel in asking numerous unnecessary questions in the cross-examination of this witness, and unnecessarily prolonging the cross-examination through several days as an evidence of deliberate intent on the part of the defendant's counsel to prevent the complainant from closing its testimony within the time assigned by the court.)

A. I have no recollection of having this fact mentioned
2233 to me, nor do I believe it was mentioned to me.

485 R. X Q. Was it reported to you how many attempts were made to flash up lamp No. 1, before the 22-candle test was made?

A. I have no recollection of such a report, and do not believe that it was reported.

(Signed) JAMES W. PACKARD.

Testimony of Walter K. Griffin.

Counsel for complainant states that he would like to ask Mr. Griffin, counsel for defendant present, who has been sworn a witness in this case, some questions in behalf of complainant.

1 Q. Will you please state whether or not you cross-examined the witness Packard in part or in whole on information supplied you either directly or indirectly by the workman Kammer?

A. In part I did, using such information as a guide to me in the course of my questions.

Direct examination closed.

The witness, WALTER K. GRIFFIN, states as follows:

I never saw or heard of Mr. Kammer until the Saturday before the examination of Mr. Packard. Mr. Kammer then came to the office where I was, and was after a short conversation taken by me to the office of Mr. Lowrey, counsel for defendant, and in the presence of each of us for the first time made a statement as to certain experiments at the factory of the Sawyer-Man company. Prior to this neither Mr. Lowrey, myself, nor so far as I know, any one connected with defendant or the Edison Electric Light Co. had any knowledge of or connection with Mr. Kammer, and the statement by him then made was the first information as to the alleged experiments received by us. This was after Mr. Kammer had left the Sawyer-Man company. * * *

WALTER K. GRIFFIN.

2234 NEW YORK, *April* 22, 1889.

Testimony of Franklin L. Pope, a Witness on the Part of Complainant, Taken Before Caroline E. Davidson, Special Examiner.

Present: Thomas B. Kerr, Esq., of counsel for complainant, and Walter K. Griffin, Esq., of counsel for defendant.

FRANKLIN L. POPE, being duly sworn, deposes as follows in answer to questions by counsel for complainant:

192 Q. Are you the same Franklin L. Pope who testified on behalf of the complainant in this case on May 8th, 1888?

A. I am.

193 Q. I call your attention to the testimony of Thomas A. Edison, on behalf of the defendant, and particularly to question and answer 485; what is your understanding of Mr. Edison's historical position with regard to electric lighting?

A. While I agree in many respects with the statement of Mr. Edison as to the condition of the art of electric lighting when he commenced his experiments, which as I am informed and believe was in the month of September, 1878, yet I judge from his testimony that he could not have been fully informed in respect to the work which had been done by others; and hence I find myself obliged in some particulars, to differ with him in my opinion as to the precise relation of his own work, not only to that of other workers in the same field, but to the general problem of commercial incandescent lighting. It is quite true that at the date of the commencement of Mr. Edison's experiments the problem of commercial incandescent lighting had not been solved, although much had been done in the direction of its solution. Other investigators had been industriously at work upon the problem for some time before Mr. Edison turned his attention to it, especially William Edward Sawyer and Albon Man in this country, and St. George Lane Fox in England.

2235 I do not altogether agree with Mr. Edison in his definition of the problem of incandescent lighting as it awaited solution in 1878. It was not, as I conceive, limited merely to the problem of superceding gas as a house-to-house illuminant to be distributed from a central station, although this was a very important, and strictly speaking, perhaps the most important, field of application for incandescent lighting. My own view of the matter is that there were at least three distinct and well-defined applications possible to the incandescent electric light, in either one of which it might have been applied, as it has been, with great commercial advantage, even if its application had failed to be successful in the others. These three applications are:

1st. General, domestic or house-to-house lighting, now generally termed "central-station lighting."

2nd. The lighting of detached buildings or groups of buildings, such as manufactories, hotels, apartment houses, railway stations and ships, usually known as "isolated lighting."

3d. The lighting of streets and squares, railway stations and yards, and the like, usually termed "municipal lighting."

Each of these three adaptations presents certain special features different from the others. In central-station lighting, the two most important points are, that the lamps shall be individually controllable, at the pleasure of the consumer, that is to say, that any lamp in the system may be extinguished or relighted without affecting any of the others; and that the amount of copper required for the conductors shall be reduced to a minimum, for the reason that the average distance to which the electric current has to be transmitted from the generator to the consumers is necessarily very considerable. In isolated lighting the independent control of the lamps is in most instances quite as important as in central station lighting, but the question of the economy of the copper in the conductors is relatively of very much less importance, as the distance to be traversed, lying within the boundaries of a single
2236 building, is comparatively small. In municipal lighting, the
independent control of the lamps is a matter of little importance, as the service permits that large numbers of lamps or groups of lamps may be lighted and extinguished simultaneously. It is scarcely necessary to add that a constant and uniform electric pressure, producing an equally constant and uniform current in all the lamps is necessary in either system.

I have thus carefully defined what I conceive to be the principal application of incandescent lighting, in the endeavor to clear up the confusion which appears to exist in reference to the application of lamps of the same type, having different structural details, in order to adapt them to different classes of service.

In my opinion, it will not be far out of the way to fix upon the year 1877 as the date when the attention of inventors and experimenters was first strongly directed towards the production of a system of supplying incandescent electric lighting for domestic purposes by means of the dynamo-electric generator.

At this date the dynamo-electric machine as a source of almost unlimited electric energy had already been brought to a good degree of perfection. It had become a standard article of manufacture and sale, both in Europe and in the United States. Mr. C. W. Siemens of the firm of Siemens Brothers, London and Berlin, testified before a select committee of the British House of Commons on April 29, 1878, that his firm had sold, during the year- 1877 and 1879, 475 dynamo-electric machines for which they had received £57,000, nearly all of which had been used for electric lighting. In reference to the performance of these machines he said: "So complete is the transformation of mechanical into electrical energy that the most recent careful experiments which have been made by Mr. Louis Schwendler for the Indian Government, and by Dr. Hopkinson, show that the loss in effecting this transfer does not exceed

12 per cent." Machines of the same character were being
2237 sold in 1877, in this country by Wallace, Weston, Hochhausen and Brush, some of which were probably quite as efficient as the Siemens machine just referred to. I think, therefore, that it may fairly be considered, that by the end of 1877 the problem of the economic production of electricity in any required quantity by steam or water power was practically solved. The remaining portion of the problem, at least so far at it relates to the present subject, incandescent electric lighting, was three-fold, namely, first, distribution, second, utilization, third measurement.

These three matters are so related to each other that it is necessary to consider them to a certain extent, as Mr. Edison has done in his answer to question 485, with reference to their mutual relations. I quite agree with Mr. Edison in his opinion that—

"It was not only necessary that the lamps should give light and the dynamos generate current, but the lamps must be adapted to the current, of the current of the dynamos, and the dynamos must be constructed to give the character of current required by the lamps, and likewise all parts of the system must be constructed with reference to all other parts, since, in one sense, all the parts form one machine, the connections between the parts being electrical instead of mechanical. Like any other machine the failure of one part to co-operate properly with the other part disorganizes the whole and renders it inoperative for the purpose intended."

Nevertheless I am of the opinion that the invention set forth in the patent in suit, relates solely to the portion of the problem which has to do with the utilization of the current and has no connection, as an invention, with the question of distribution, or the question of measurement. It is an improvement in the construction of an incandescent lamp and stands by itself. It might have equally well happened, as in fact it did happen, that methods of distribution and methods of measurement of the electric current had been in-
2238 vented before, or on the other hand, that the lamp had been invented first and methods of distribution and measurement afterward invented and applied to it.

I will first consider some of the statements of Mr. Edison, with which I am unable to agree. He says:

"The subdivision of the electric light into small units comparable with that of the ordinary gas jet, was what I thought was required. The general scientific opinion was that this could not be done. Even after it had been announced in the public press in 1879, that it had been accomplished by me the statement was discredited and was pronounced by many eminent scientific men, both in this country and abroad to be an impossibility. A committee was appointed by the English Parliament to examine into the general subject, and they called before them as witnesses nearly all of the prominent scientific men in England, all of whom, with the single exception of Mr. Tyndall, testified that, in their opinion, the subdivision of the electric light was an impossibility. Mr. Tyndall said he would hardly go as far as to say it was impossible, but he would not like to undertake the solution of the problem."

I think Mr. Edison is in error in respect to the tendency of general scientific opinion; there is in all scientific countries a contingent of what may be called semi-scientific persons, who make up in pretension what they lack in accurate information and knowledge. Such persons are always very prominent in the newspapers and in the so-called scientific journals of the more popular class, and create an amount of noise out of all proportion to their real importance; and it seems to me as if Mr. Edison had in the present instance mistaken the opinions of such persons for those of the scientific world. I have here the report of the select committee of the British Parliament on electric lighting, referred to by Mr. Edison, from which I will read the extracts which 2239 will serve to show what were the opinions actually held by the most eminent scientific men at this time. The testimony from which I shall quote, was given between April 17, and May 23, 1879. The only witnesses examined who may fairly be called scientific men skilled in electricity, were Conrad W. Cooke, civil engineer, William H. Preece, electrician to the British post office; Charles W. Siemens, of Siemens Bros., electrical engineers; Prof. John Tyndall, successor of Faraday in the Royal institution; Dr. John Hopkinson, civil and electrical engineer, and Sir William Thomson of the University of Glasgow. There were other witnesses of equal standing, who made no pretensions to any specific knowledge of electrical matters, and to whom I need not refer. Newspaper accounts of Mr. Edison's work had already reached England, and most of the witnesses were put upon inquiry as to their opinion of the claims made in his behalf. Mr. Cooke's testimony was as follows:

"388 Q. Have you given attention to the question of obtaining light by means of incandescence, necessitating a closed circuit?—I cannot speak with any practical experience of that. My view of it is that you would have a far greater loss; it could not be done so economically, but it would probably be applicable in cases where economy was not so much an object, and where there was some special reason for dividing it.

"425 Q. Dr. Siemens, in referring to Mr. Edison, who is credited with having recently invented a machine for subdividing the light, expressed some doubt on the subject, and stated that he thought that it was not as promising as the reports indicated; do you know anything about that?—We really know very little about it. A few newspaper paragraphs have appeared on the subject, and I have been very much interested, as everybody has. His nephew told me, himself, that he has seen, I think, over 200 lights on one circuit. I must say I should like to see it myself, and that is all that I can say."

2240 The views of Mr. Preece will appear from the following extracts:

"515 Q. Then, according to your view, the electric light is really very economical when it is used for giving central lights, but not when it is used in a subdivided form?—It is only economical when one machine is used to produce a single light.

"516 Q. And any departure from that means waste, economically speaking?—Certainly."

Mr. Siemens testified as follows:

"258 Q. Then, as to its application to dwellings, it would, I suppose, be a work requiring some further experiment and a work of some difficulty, before you could hazard an opinion as to its being used in dwellings generally instead of gas? For instance, the expense of keeping the carbons and all the machinery in order would almost prohibit its being used generally in dwellings, would it not?—There would not be much machinery if central pumping or power stations were adopted. The consumer would only have his electric candle or his electric lamp to keep in order, and that would not involve any very serious difficulty. But if you subdivided the electric light, I think it perhaps would become an expensive light.

"259 Q. Has your attention been called to some of the more recent experiments of Mr. Edison, and to the success which he is stated to have achieved in subdividing the light, and making it applicable for rooms and dwellings, and so on, with great ease and cheapness?—I have, and I think Mr. Edison can, no doubt produce by his means a very steady and possibly an agreeable light.

"260 Q. And a cheap light, he claims, I believe?—Dynamically speaking, I think he has to prove his case as yet. Our experience, as far as I can judge from my own, leads me to an opposite conclusion.

2241 "261 Q. That is, to a conclusion opposite to that which is said to have been the result of Mr. Edison's recent experiments?—Yes. The dynamo machine which Mr. Edison proposes, I think is not promising."

It should be stated that the dynamo machine here referred to is the earliest form proposed by Mr. Edison known as the "tuning-fork dynamo" and not the one which he subsequently adopted for practical use.

The remark attributed to Professor Tyndall by Mr. Edison was not a part of his testimony before the committee, but is in substance what he is reported as having said a few weeks earlier, in the course of a public lecture on the subject of electric lighting. His testimony, as printed, on this point is as follows:

"78 Q. Have you, from a scientific point of view, paid attention to the experiments reported to us as having been made in America by Mr. Edison?—I have paid a good deal of attention to that subject. Mr. Edison is an uncommonly clever man, and although one sees very serious difficulties in his way, one would be hardly entitled to say that he will not overcome those difficulties; but I do not know that he has up to the present time overcome them."

In his answer to question 93, as to the practicability of using platinum or iridium for electric lighting, he said:

"I am afraid, as regards public illumination, incandescency will not do; the expenditure would be too great."

Further on he *he* made some additional statements in reference to incandescent lighting which I will quote:

"105 Q. You showed us the ignition of platinum wire by the pas-

sage of the electric current; have not experiments been made to use the ignition of such a wire and inferior conductors, or of alloys with
iridium, and so on, with a view of using that as the source of
2242 the electric light instead of the carbon points?—I do not
know that that has been proposed with regard to public illumination, but I remember with the greatest distinctness, more than 30 years ago, seeing a lamp formed upon that principle and exhibited in Manchester. The incandescence of platinum wire by the electric current was known before Davy made his experiments in 1810. Children raised platinum to incandescence by his battery; and at the time to which I refer, I saw a very pretty lamp on a table in Manchester ignited by a voltaic current; but I do not know that that has been produced for public illumination; I believe that the waste of electricity would be inordinate with a continuous conductor."

The following questions and answers will be sufficient to show the opinion of Dr. Hopkinson on the subject:

"622 Q. What is the reason that a large electric arc produced, say, as a central light by a single machine, gives you a considerably greater illuminating power than when it is divided into small electric arcs?—It is no doubt due to the higher temperature to which the substance of the carbon is raised.

"632 Q. From your scientific investigations of the subject, do you agree with some other witnesses who have stated that the electric current when divided into various electric lights will decrease according to the squares or the cubes?—I think not, certainly. I think those deductions are based upon assumptions which any one would not have the least difficulty in setting aside.

"623 Q. With regard to the electric light, the machinery now known for producing the energy is very much more advanced than the means of displaying that energy by carbons or lamps?—Undoubtedly that is so.

2243 "650 Q. As I understand it, the real expense of the iridium
light consists in this, that the iridium being a continuous conductor, there is great waste of power in the consequent flow of electricity from which you are getting no light?—The real loss in these incandescent lamps lies in this, that the temperature cannot be driven to so high a point as when the electric arc is used; but not even iridium, which has, perhaps, the highest fusing point of any metal, will stand the temperature of the electric arc without melting or being volatilized."

I close these extracts by making the following quotations from the evidence of Sir William Thomson:

"1753 Q. If then, the electric light is such an economical producer of the waves that we call luminous rays, do you consider that the electric light has a great future before it or not?—A great future. In the immediate future, I anticipate a great extension of the practical usefulness of the electric light. In a future somewhat less near, I anticipate the use of the electric light for every case of fixed lights, whether in large rooms or in small rooms, or in great public halls or in passages and staircases leading to them, and even in fixed lights in the lobbies and staircases of private houses.

"1754 Q. Then you think that the use of the electric light is not the dream of a savant, but a practical possibility in the future?—Certainly. The electric light has been in dreamland for 60 years, and it has now come into the world of realities.

"1755 Q. And it is now rapidly progressing?—It is now rapidly progressing, and in good hands. A great deal of good work is spent upon it at this time, and there is immense promise in the work that is now being carried on by practical men upon the electric light.

2244 "1756 Q. Your reason for supposing so is, that there is now a prodigiously greater economy in the transformation of mechanical force or energy into light than there formerly was?—That is my reason.

"1779 Q. Would you allow me to ask you about the division of the electric light into various small lights; scientifically, do you agree with calculations, the result of which have been put before us, that the effect of a division must be, in some cases, to decrease the light so divided, according to the squares, or according to the cubes of the distance?—We have no scientific law of the economy of the electric light in different degrees of division and concentration; but practice and theoretical guesses seem to agree in making the economy much less when we spend the same quantity of energy, for example, in ten feebler lights than when we spend it in one strong light; when we do this we do not get nearly one-tenth part of the whole light by any of the plans hitherto in use.

"1780 Q. But there is nothing in the mathematical discussion of the question that should render that reduction necessarily by the squares or cubes?—No; it is quite possible that a plan of using electric energy for light might be found and may yet be found in which ten feebler lights will give a sum of light equal to that obtainable by the same energy in one concentrated light.

"1848 Q. Supposing that we had a lamp in a dining-room, and that after dinner I did not want the lamp any more, how should I put it out?—If there are other lamps in series, you would do it by short-circuiting it. It may be short-circuited through a resistance, but then there will be a waste of light.

"1849 Q. Then there is the same cost for that lamp, as 2245 when it was burning, with the exception of the carbon?—Yes, but with proper regulators by inventions not yet made, the machine will have a governor according to which, when you short-circuit without resistance any one of the lights, the machine will not give more current than you want for the other light or lights, whether in the same circuit or in parallel circuits."

It will appear from the extracts which I have quoted, that the leading scientific men who testified before the parliamentary committee were very far from expressing the opinion that the "subdivision of the electric light was an impossibility." The testimony of Dr. Hopkinson, especially, who was really the best authority of any of the witnesses, was emphatically in favor of the possibility of doing it, and that of Sir William Thomson scarcely less so. Many of them expressed doubts as to the economy of the light when produced by an incandescent burner of platinum or iridium, which was the kind with which Mr. Edison had experimented up to that time, and the result showed that they were entirely right, for before the close of the same year, 1879, Mr. Edison himself was obliged to abandon the attempt to produce a commercial system of lighting by the incandescence of metals on account of its great cost.

A review of the testimony above quoted, shows clearly that in 1879 it was fully recognized that the future commercial success of incandescent lighting depended upon the utilization of some other substance than platinum or iridium for the incandescent lamp. In my opinion, the statement cannot be successfully controverted, that the solution of this problem was ultimately reached by the invention of a lamp having a burner made of organic carbon of an arch or horseshoe form, and placed in a transparent chamber free from carbon-consuming gas. No successful incandescent lamp has ever yet been made which did not involve this construction, and on the other hand this construction is found in every successful lamp which is in use to-day. The adaptation of this typical lamp to 2246 different circumstances and different conditions, such for instance, as making the carbon thin and of high resistance, when it is designed to be used in parallel with the generator, or thick and of low resistance when it is intended to be used in series with the generator, may, in my judgment be considered more properly as matters of electrical engineering, than of invention in the strict sense of the term. The lamp, in its essentials, had first to be invented, but when this had been done, the adaptation of it to *to* different conditions by the exercise of engineering skill or by the making of subsidiary inventions, followed as a matter of course, hand in hand with the gradual progress of the art.

Mr. Edison, in his testimony, considers the problem as if it related solely to the distribution of electricity over large areas in competition with gas as an illuminant, but as I have before said, I regard that as only one portion of the general problem. In support of this opinion I quote from the affidavit of Edward H. Johnson, president of the Edison Electric Light Company, made June 29th, 1888, in the motion papers for a preliminary injunction on behalf of that company against the Consolidated Electric Light Company, in the U. S. circuit court for the southern district of New York. Mr. Johnson says:

"I am president of the Edison Electric Light Company, complainant herein * * * I have been connected with the various Edison companies for some years past, and am entirely familiar with the business carried on by such companies * * * There are in the United States at the present time about 130 of such central stations representing in the aggregate about 400,000 lamps * * * There have been sold in the United States about 1,000 of such isolated plants and their aggregate lamp capacity at the present time is about 300,000."

2247 It appears from these figures that the extent of the isolated electric lighting of Mr. Edison's own company is three-fourths that of the central-station lighting, instead of being, as might be inferred from the statements of some of the witnesses, a comparatively unimportant portion of the business. Mr. Edison says:

"The problem that I undertook to solve was, stated generally, the production of the multifarious apparatus, methods and devices, each adapted for use with every other, and all forming a comprehensive system whereby electricity, properly controlled and directed, could be distributed over large areas through the streets of a city, and supplied to houses in which it would feed incandescent electric lamps of moderate candle power, which would be entirely under the control of the householder, the whole to be on the same scale as the present system of gas distribution, and affording the same character of convenience to the users."

On the 28th of January, 1880, Mr. Edison executed an application for a patent for a system of electrical distribution, which was filed in the Patent Office, on February 5th, 1880, but was not finally issued until August 30, 1887, as No. 369,280. This specification may, I think, be fairly assumed to represent the state of the art of electrical distribution at that date, as it had been developed by Mr. Edison. In order to facilitate a comparison between this specification and the specifications of others who had been at work upon the same problem, so as to show at a glance the relation of Mr. Edison's work to the general state of the art, I will make extracts from this specification placing them side by side with extracts from the patents and publications of others of prior date.

2248 *Extracts from Specification of Edison's Patent No. 369,280. August 30, 1887.*

Filed Feb. 5, 1880.

The object of this invention is to arrange a system for the generation, supply, and consumption, for either light or power, or both, of electricity, that all the operations connected therewith requiring special care, attention, or knowledge of the art, shall be performed for many consumers at central stations, leaving the consumers only the work of turning off or on the supply, as may be desired—in other words, to so contrive means and methods that electricity may be supplied for consumption in a manner analagous to the systems for the supply of gas and water, without requiring any greater care or technical knowledge on the part of the consumer than does the use of gas or water, in order that economy, reliability, and safety may be insured.

In carrying the invention into effect, a city, town, village, or locality may form one district, or, if the extent of territory makes it desirable, may be divided into several districts. In each district I provide a certain station, at which are grouped a suitable prime motor or several motors, dependent upon the amount to be supplied, generators or means for converting the prime motive force into electricity, and means for determining and regulating the amount of electricity generated and supplied, in order that a constant pressure of electricity (so to speak) may be kept up. The prime motors are any suitable engines, steam or water, and one or a series of two or more is provided, as may be necessary, each of which is provided with its own system of shafting and belting, driving a number of magneto-electric machines, the number actuated by one prime motor being hereinafter termed a "battery." . . . .

At the central station all the supply-generating coils or batteries thereof are connected to conductors on the multiple-arc system, and from these conductors at the station, main conductors (which for convenience may be called
2249 simply the "mains") connected thereto, also on the multiple-arc system, lead in any and all desired directions for conveying the energy to the points where work, either by translation into light or motive power, is to be done. All of such conductors from the generators at the station to the lamps are made in pairs—one for the outgoing current and the other for the returning

Extracts from the Specification of Sawyer's Patent No. 194,111. August 14, 1877.

Filed June 22, 1877.

The object of my invention is to supply the streets, blocks, or buildings of a town or city in a practicable manner with any desired quantity of electricity for the purpose of electric illumination, electroplating, electric heating, the running of electro-magnetic engines, &c. I place the generator or generators of electricity in any convenient portion of a locality, whence I carry the necessary conductors over or under ground to the streets, blocks or buildings in which the electric current is to be utilized.

The advantages of my invention are that it enables householders to obtain a supply of electricity for any purposes without the care and inconvenience attending the maintenance of local galvanic batteries; that it greatly reduces the cost of electricity to consumers; and, lastly that it renders practicable the lighting of buildings by electricity.

My generators may be in the form of the galvanic battery, or, what is preferable, magneto-electric machine driven by wind, steam, water or other power.

Extract from the Specification of Sawyer's Patent No. 196,834. Nov. 6, 1877.

Filed August 10, 1877.

For the proper performance of the work devolving upon an electric lighting system, the quantity of current required being so great, it is impracticable to employ the earth for the return circuit. It is therefore necessary, in running two such electric conduits, as the two railroads instanced, to run return conduits for each, and where many such are needed the expense is very considerable.

It is apparent, further, that to insure the requisite conductivity for the great volume of current required, the main conductors must be very large, and as a single conductor traversing a territory (letters patent No. 194,111) is forced to take many devious paths, passing into and out of houses, or into and out of rooms, to or from lamps or engines, in all of which deviations the large size of the conductor must be maintained, the expense of construction is very great. By placing my circuit-continuity preserving devices, however, in branch circuits, the branches alone pursuing the devious paths mentioned in running across from the two large mains or conductors, the branch conductors may be small, for if I wish to divide the current

current of electricity, the circuits throughout the system being complete or round metallic circuits, the conductors of which are well insulated from each other and from the earth. . . . .

To avoid any appreciable variations and insure uniformity, it is essential that any lessening of pressure be immediately indicated, in order that just sufficient energy be generated and sent out to keep up an equal flow through the circuit of each translating device—that is, that the pressure be kept up uniform, whether more or less translating devices be in circuit. This is attained by providing at the central station means for *for* constantly indicating the pressure and for regulating the production if appreciable variation be indicated. . . . . The translating devices in each house may be either for light or power, or both. For light, the electric light, consisting of an incandescing material hermetically sealed in glass (shown in other applications filed by me) is preferred. This lamp is made of a high resistance in comparison with that of any electric lamps which, to my knowledge, have been proposed.

In lights heretofore proposed the endeavor seems to have been to lessen the resistance of the carbon, none having been suggested of higher resistance than, say, ten ohms; but I have discovered that a very much higher resistance—say one hundred ohms—must be used, in order that a number may be economically and successfully used in a system. . .

As ordinarily proposed, each electric light requires its own regulator, which usually is either thermostatic or magnetic, breaking the circuit or bringing in resistance—in any case making a cumbrous lamp, requiring delicate management and constant attention. By
2250 regulating at the central station
entirely, I am enabled to use a small separate lamp, which may be used with the exercise of no more than ordinary care or attention. . . .

The means for measuring insure accurateness in furnishing a basis for equitable charges for the amount used by any particular consumer.

flowing in the two main conductors, and thence through the branches, among, say, fifty branches, the wire forming the branches need be only one-fiftieth the mass of that forming the two main conductors; hence, instead of running a single very large and expensive conductor into and from houses, to and from each lamp or engine, I have only to run two main conductors, and by small and inexpenive branches reach the lamps or engines. The current is evenly distributed throughout all of the branches, and my circuit-continuity preserving devices, whether those of my present invention or those of letters patent No. 194,111, or any others of like function, enable me to light or put out any one or more of the lamps, or start or stop any one or more of the engines operated by the current common to all, without decreasing or increasing the flow in the other branches.

Extracts from Specification of Sawyer & Man's Patent No. 205,305. June 25, 1878.

Filed May 25, 1878.

The objects of our invention are, first, to supply to an electrical circuit or circuits containing electric lamps an absolutely uniform volume of current, in order to obviate the unsteadiness which has characterized most attempts at distribution; second, to supply automatically, only so much current as may be necessary to meet the demand, thereby insuring the economical and satisfactory operation of a distributing system; and, third, when the demand for the current is lessened or increased by the removal of lamps from or their introduction into the circuit or circuits supplied by the generator, to cut off steam from, or add steam to, the engine driving the generator, in order that there may be no waste of power when the demand for the current calls for a limited application of it merely. . . .

The regulator of our invention so controls the steam or other power actuating the generator of electricity that this power is increased or diminished, as the demand for the current is increased or diminished; and while we have shown the result as accomplished in one way, we do not confine ourselves to the precise apparatus and the manner of its operation shown and described.

2251 The patents of Sawyer, and of Sawyer and Man, from which the foregoing extracts have been made, were issued and published a considerable time before the commencement of Edison's experiments in September, 1878, and were therefore a part of the state of the art. Patent No. 194,111, was dated August 14, 1877, and No. 196,834, November 6th, 1877, and No. 205,305, June 25, 1878.

In stating in detail the advance made by him in the art of incandescent electric lighting, in his answer to Q. 485, Mr. Edison enumerates seven different things which were necessary to be done, which may be summarily stated as follows: First, to adopt a fundamentally correct system of distributing the electric current and then to devise lamps which could be worked practically on such a system.

A fundamentally correct system of distribution is that of parallel or, as it is sometimes termed, multiple-arc distribution. This was adopted by Mr. Edison, but had been fully described in the prior patent of Sawyer 196,834, of November 6, 1877, in which, however, he disclaims it as not being a part of his invention, it being already well known in the art of electrical distribution, as may be seen by reference to the prior patent, of Woodward, Khotinsky and others, in evidence in this case. Given a system of distribution in parallel arc, the only thing remaining to be done calling for the exercise of invention, as distinguished from the work of the skillful electrical engineer, was to provide a device which should regulate the supply of electric current at its source in proportion to the consumption. This it appears had been accomplished to a certain extent as early as 1875 by Professor Moses G. Farmer of the United States torpedo station at Newport, Rhode Island. No description of this apparatus, however, was made public until 1880, and therefore it cannot properly be regarded as a part of the state of the art; but in the patent of Sawyer and Man 205,305 referred to, we find for the first time an apparatus for automatically regulating the production of electricity at its source in accordance with the requirements of the consumers;
2252 a plan which is now in universal use, and which I regard as lying at the very foundation of all the approved modern systems of electrical distribution—not only for electric lighting, but for all other purposes.

Second, to devise a suitable electric lamp for use in such a system. I am of the opinion that the lamp described in the patent in suit fulfills the condition of a suitable lamp; by which I mean a lamp comprising an incandescing carbon of organic material and of an arch or horseshoe form enclosed in a transparent glass chamber, from which oxygen or other carbon-consuming gases have been removed. I consider that the adaptation of this lamp to the special requirement of each case is properly a matter of engineering, or of additional subsidiary inventions, the lamp of the patent in suit being, in my opinion, one of a type which adapts itself readily to any required modification for such purposes.

Third, to devise means of measuring or determining the amount of light furnished to each consumer. This was first done, so far as my knowledge extends, by William E. Sawyer, whose electric meter is described in his patent No. *No.* 210,151, for which the application

was filed on October 17, 1878, and patented November 19, 1878, a description of which was published in the Scientific American of December 7, 1878, page 354. Mr. Sawyer's meter consists of a set of indicating dials similar to those of a gas meter, which when in operation are moved at a uniform rate by a chronometer. This device registers the number of hours each lamp is run, and inasmuch as each lamp when burning is necessarily traversed by a constant current, the indications of the dials may equally well register the quantity of electricity used. I consider this a perfectly accurate and efficient meter, and one which might perfectly well be used in the present state of the art, were it not that other meters more simple and less expensive in construction, and less inconvenient in maintenance have since been invented and applied. The
2253 earliest patent of Mr. Edison, relating to meters, which I have been able to find is No. 251,545 of December 27, 1881, the application for which was filed on March 20, 1880, a year and five months later than the filing of Sawyer's application.

Fourth. To devise a comprehensive system of conductors for general electrical distribution.

While there can be no doubt that such a system of conductors forms a most essential part of a general scheme of distribution, I nevertheless regard it as more properly a matter of engineering than of invention in the strict sense of that term. I mean by this, that when the general requirements of such a system had been formulated and set forth as they had been in the patents of Sawyer and Man, and subsequently in the patent of Edison, it was perfectly certain that the engineering skill could be found to devise and construct a proper system of conductors. I do not mean to be understood by this that it might not require much study, many experiments, and the making of a large number of subsidiary inventions, these inventions being, however, of a class which are absolutely certain to be made by somebody, as soon as the necessity for them becomes clearly apparent. The history of the art shows that the utmost credit is due to Mr. Edison and his assistants, for the thorough and complete manner in which they devised and carried out a scheme of electrical distribution in accordance with the general plan which he (Mr. Edison) had first fixed upon. But it is nevertheless true that other and wholly different schemes of distribution have since been devised, carried into effect, and are now in extensive use, and which under some conditions are even more economical and efficient than that employed by Mr. Edison.

Fifth. To devise means of producing a uniform pressure over an extended area of distribution, irrespective of the number of lights in use, and also to devise means for regulating at the point where the current is generated the equality of pressure throughout the lighting area. What I have said in reference to the fourth
2254 head, is equally applicable to this one. The required uniformity of pressure may be largely secured by the use of the automatic regulator of Sawyer and Man, which I have already referred to, which is described in their patent No. 204,305 of June 25th, 1878. The uniformity of supply in accordance with the con-

sumption having been provided for, it would only be necessary to apply proper engineering skill to so arrange, interconnect, and proportion the sectional area of the distributing conductors, to permit this supply to diffuse itself uniformly and properly over the entire area of distribution. This is of course a somewhat intricate and difficult matter in a large district, but in a small district, or in an isolated plant, it presents no difficulty which could not be overcome by the use of the ordinary knowledge which every skilled workman ought to possess.

Sixth. To devise economical dynamo machines and means for connecting, disconnecting and regulating the same. There was very little left for anybody to invent in respect to the essential features of dynamo machines at the date when Mr. Edison first turned his attention to them. The only improvements which have been made by him, or by anybody else, since 1878, have been in matters of detail and of proportion. In these latter respects a constant improvement has been going on at the hands of so many different persons that it would hardly be possible to enumerate them, ever since 1878, and the electrical output of the machine in proportion to the weight of metal used in its construction has been very greatly increased. Precisely the same course of improvement has been going on in the steam engine ever since the days of James Watt, but nevertheless the engine of Watt, like the dynamo machine of 1878, was a practicable and useful machine, and applicable in a large degree to the requirements of modern service. The arrangement of these dynamos in reference to the requirements of the service which they are designed to perform, is again a matter of engineering, requiring special adaptation and treatment in each particular case.

2255 Seventh. To devise means for preventing the current from becoming excessive upon the conductors so as to cause fire or other injury and to provide switches, lamp-holders and other subsidiary devices. The appliance which is in universal use for guarding against excessive currents is known as the safety fuse, which is a section of each conductor so arranged as to be fused and thereby interrupt the current before it becomes of sufficient strength to overheat the remaining portion of the conductor. This device was also an invention of Sawyer and Man and is described in their patent No. 205,303 of June 25th, 1878, page 2. I quote from the specification:

"In place of the safety switch, we may interpose in the circuit a section of a conductor more readily fused than the conductors constituting the rest of the circuit, so that when there is too much current this section shall be instantly melted and the continuity of the circuit destroyed."

This patent it will be seen was issued some three months before Mr. Edison commenced his work, and was therefore a part of the state of the art. The earliest mention I find of the safety fuse in his patents is in No. 227,226 of May 4, 1880. Switches, lamp-holders, electric chandeliers and means and methods for placing wires that were to convey the current to the chandeliers in buildings, are all described and illustrated in an article published in the Scientific

American, of December 7, 1878, describing the system and apparatus of Sawyer and Man, so far as it was at that date made public.

The extracts which I have given are, I think, sufficient to show beyond doubt, that the state of the art of electric distribution in the year 1879, was such that it only required the invention of a suitable incandescent lamp, having a capacity to be adapted to different conditions of service, to render the scheme of incandescent lighting a commercial and practicable one. Every one of the essential features of such a scheme, as enumerated by Mr. Edison in his 2256 answer to question 485, which was a subject of invention as distinguished from a subject for the exercise of the skill and knowledge of the engineer, had been invented and patented by Sawyer and Man, or was otherwise a part of the common knowledge of the public in respect to the state of the art before Mr. Edison took up actively the subject of electric lighting in 1878. It seems perfectly evident that Sawyer and Man were aware of the fact that a proper incandescent lamp was the only thing remaining to be invented to insure the commercial success of the scheme, to which Mr. Sawyer had devoted himself, as the evidence shows, since the beginning of 1877. That this was actually the fact is proven by the circumstance that within a few months after the announcement of the existence of a lamp possessing the essential characteristics of the lamp set forth and claimed as the invention of Sawyer and Man in the patent in suit, that incandescent electric lighting plants were in actual and successful public use for the first time, and that such have continued to be in uninterrupted and rapidly increasing use from that time until the present day.

Adjourned for lunch.

Met pursuant to adjournment.

Present: L. E. Curtis, Esq., for complainant; and R. N. Dyer, Esq., and H. D. Donnelly, Esq., for defendant, and the direct examination of Mr. Pope was continued as follows:—

194 Q. Have you read the depositions given in this case by Professor Cyrus F. Brackett, Professor George F. Barker, Professor William P. Wilson and Mr. Edison as experts on behalf of defendant?

A. I have.

2257 195 Q. Professors Barker and Brackett express the opinion in substance, that in order to make the incandescent lamp practically successful for any commercial purpose a radically new departure from the practice in vogue prior to 1880 was necessary, which consisted essentially in making the incandescent conductor of very high resistance so that the necessary electric energy required to give the light could be conveyed to the lamp in the form of a maximum of tension and a minimum of current, and that this radically new departure is first found in the New York Herald article, in evidence herein, and in Mr. Edison's patent No. 223,898, and No. 227,229. Do you agree with them in this opinion? Please give your reasons for any opinion you may express.

A. I find myself unable to agree with the witnesses Professors Barker and Brackett in the opinions which have been quoted in the

question. In the first place it cannot properly be considered that a high resistance in the incandescent conductor is an essential feature of the modern incandescent lamp. It would, in my opinion, be much more nearly the truth to say that the radically new departure which was necessary, consisted in the invention of a type of lamp which was capable of having its resistance modified at the will of the constructor, so that he might be enabled to produce a lamp which would give the best results under any one of the different conditions which are found to occur in actual service. It is quite true that in the particular scheme of long-distance distribution for central-station lightning, which was contemplated by Mr. Edison at the time the publication in the New York Herald was made, high resistance in the incandescent carbon was an extremely important desideratum, but it is equally true that in other and more recent schemes of distribution accomplishing precisely the same result, but by different instrumentalities, it has been found that a much smaller resistance in the lamps is preferable both on the score of economy and of efficiency. Again there are other methods of distribution such as that known
2258 by the name of the "municipal system" in which the lamps are placed in series, and in which it is found advantageous to make the resistance of the lamps comparatively small, as small as one-tenth and even less of the standard which would give the best results in a system of long-distance multiple-arc distribution. I consider therefore that the importance of the high-resistance incandescent conductor relates not to the incandescent lamp *per se*, but to the incandescent lamp when employed in connection with a particular one of several different schemes or plans of distribution, each of which possesses certain advantages over the others under certain conditions. If there were no other possible commercial application of the incandescent lamp except in connection with a direct-current multiple-arc system of distribution over a wide area, then the opinion expressed by Professors Barker and Brackett might be a more tenable one. But as I have already said, it seems to me that the new departure which marked a radical change from the practice which had before prevailed, consisted in making the incandescent conductor of such a material and of such a form that its resistance might be made as great as might be necessary under the particular conditions of its proposed use. In my opinion, the invention of an incandescent conductor made of organic material capable of being first formed and then carbonized, in the form of an arch or horseshoe, this being substantially the invention set forth and claimed in the patent in suit, rendered it possible for the first time to provide a lamp with a long, thin, flexible and sufficiently elastic conductor of high specific resistance and capable of withstanding a high temperature without disintegration. Given such a structure, and the adaptation of it to various methods of distribution and various conditions of use, would seem to fall more properly within the province of the skilled electrician than within that of the discoverer or inventor.

Even if we conceded the idea of making an incandescent lamp

of very high resistance to have really constituted a radically
2259 new departure and an important improvement in the art of
incandescent lighting, I do not consider that it was first disclosed in the New York Herald article in evidence herein, the date of which is December 21, 1879. In a paper read by Professors Elihu Thomson and Edwin J. Houston before the American Philosophical Society, on November 1st, 1878, which is printed in volume 7, page 25, of the Telegraphic Journal and Electrical Review, of London, the authors say:

"In respect to the relations that should exist between the external and internal work of dynamo-electric machines, it will be found that the greatest efficiency will, of course, exist where the external work is much greater than the internal work, and this will be proportionately greater as the external resistance is greater."

In this statement are clearly formulated the general conditions of maximum efficiency in an electric circuit supplied from a dynamo-electric machine. The application of it to any particular scheme of electrical distribution and utilization is a matter of engineering detail guided by and founded upon mathematical computation. Given the statement that the efficiency is proportionately greater as the external resistance exceeds the internal resistance, and it necessarily follows that the total resistance of the entire group of lamps supplied from the dynamo should be as great as possible, provided the resistance of each individual lamp does not become too great to permit a sufficient current to pass to maintain it in a condition of incandescence, under the eletrical pressure which the machine is capable of exerting.

The specific application of this general law to the case of a system of incandescent lamps supplied from a single dynamo is clearly set forth in the patent of St. George Lane Fox, in Great Britain, No. 3989 of 1878, of which the provisional specification was filed on the 9th of October, 1878, and the complete specification on the 9th
of April, 1879. The following quotations from the specifica-
2260 tion will show that the patentee thoroughly understood the
conditions which were required in an economical and efficient system of incandsecent lighting:

"The material or alloy employed should be capable of standing as high a degree of tempera*a*ture as possible without fusing, volatilizing or falling to pieces, it should also have a high specific resistance. The higher the temperature to which the material can be raised the more economical will be the light produced, that is the light will be greater in proportion to the force or energy expended, inasmuch as the radiant energy proceeding from the surface of the material will be more and more luminous as the temperature increases. In order to prevent the deterioration of the material when incandescent, I sometimes surround it with an atmosphere of nitrogen gas. The quantity of light will be proportional to the extent of the luminous surface. The resistance of the luminous material and its extent of surface should therefore depend on the amount of light it is required to give and the electro-motive force used. Speaking broadly it may be said that the resistance of the luminous conductor should be so adjusted or fixed that the electro-motive force of the mains to which it is attached is just sufficient to develop within it the strength of current necessary to raise it to the right degree of incandescence.

In order that the electric force may be conveyed at a high tension, that is, having high electro-motive force, so that there may not be very great loss from the resistance of the conducting mains or conductors, I make the lamps when I use an alloy of platinum and iridium of lengths of fine wires so that I may get a high 2261 resistance without having a large extent of luminous surface."

* * * * * * *

"The electro-motive force of the electric conducting mains should be kept as nearly as possible constant at say 100 volts or British Association units of electro-motive force."

The electro-motive force here proposed is precisely that which has been adopted in practice by Mr. Edison and others who employ the direct system of distribution.

In this patent is also described the scheme of an interlacing network of conductors covering a large area of a city or town and supplied with current from a central station through a number of mains or feeders and having the lamps arranged thereon in parallel or multiple arc.

In view of these publications I cannot concur with Professors Barker and Brackett in the opinion that the idea of making the incandescent conductor of very high resistance was first made known in the New York Herald article and in Mr. Edison's patents, No. 223,898 and 227,229.

Adjourned to April 24th, 1889, 10 a. m.

NEW YORK, *April* 24, 1889.

Met pursuant to adjournment.

196 Q. Have you read and examined the various prior patents and publications put in evidence by the defendant herein, and read the testimony of defendant's experts in regard to the same?

A. I have.

197 Q. Do you agree with the opinion expressed by defendant's experts, Professor Bracket and Professor Barker, that in view of the prior state of the art as disclosed by the said prior patents 2262 and publications, there was no novelty in the inventions described in the patent in suit and referred to in the first, second and fourth claims thereof? Please give your reasons for any opinion you may express.

A. Professor Brackett in his answer to X Q. 38 expressly says that he does not find an incandescent conductor for an electric lamp in any one of the prior publications discussed by him in which both the carbonized fibrous material and the horseshoe shape are coexistent. In his answer to X Q. 40 he expresses the opinion that the combination of these two qualities in an incandescent conductor

does not disclose any invention, and the reason which he gives for his opinion is that whatever of advantage there may be in the form, if any, does not depend upon the material, and whatever advantage there may be in the material does not depend upon the form, and assuming as he does both the form and material separately considered to be old, concludes that their combination does not disclose any invention. In the first place, I do not agree with Professor Brackett in his assumption that the use of carbonized fibrous or textile material for the incandescent conductor of an electric lamp is old. When asked in X Q. 41 where such description is to be found, Professor Brackett can only cite two publications describing the carbonization of fibrous material without reference to its use in incandescent lamps, and an English patent which described an arc lamp (not an incandescent lamp) with electrodes of carbonized lignite. He says in his answer to X Q. 42 that he thinks these two publications and the English patent contain the best description he can find of an incandescent conductor for an electric lamp of carbonized fibrous or textile material. I can only say in reply to this, that the production of a carbonized fibrous material constitutes *per se* no part of the invention which forms the subject-matter of the patent in suit. The invention consists in the selection of this material for an incandescent conductor and applying it to use in such a way as to render its peculiar qualities available. And this, in my opinion, was done by making
2263 the conductor of an arch or horseshoe form, thus permitting its terminals to be mounted in rigid and unyielding supports, at the same time permitting the longitudinal expansion and contraction of the incandescent conductor under variations of temperature to be compensated by a slight variation in the degree of curvature of the arch distributed throughout its whole length in such a manner that the flexure at any one point is well within the limit of the elasticity of the material. Professor Brackett says in his answer to question 33, that an incandescent conductor of the particular dimensions shown in the drawing attached to the patent in suit, would be quite as likely to break in the form shown as it would be in the form of a straight rod, "as had been in the art before." While I do not admit, for reasons just stated, that such an incandescent conductor, even in the form of a straight rod, had been known in the art before, yet I do not agree with Professor Brackett that it would be as likely to break when made of arch form of the dimensions shown in the patent. In the first place I see no reason why the patentee should be confined to the precise thickness of carbon shown in the drawings of the patent, when every electrician skilled in the art in even the smallest degree, would know that the thickness and length of the carbon would have to be varied in accordance with the service which the lamp was expected to perform and the conditions under which it would perform it. It was just as much a matter of common knowledge to the skilled electrician, as it was for instance, to use electro-magnet coils of thick wire and a small number of turns for some applications, and a thin wire, and a large number of turns for other applications. A very moderate

amount of common sense would be sufficient to enable him to know that to develop a given amount of heat in the conductor it must be made short and thick for a strong current, and longer and thinner for a weaker current. If he had occasion to use a long thin carbon, the patent informed him that he could obtain it by the use of carbonized textile material which is one of the
2264 ways now commonly practiced. The fact that lamps now made, so far as I am aware, by many different makers, all of which, whether made with a short thick conductor or with a long thin one, are invariably in the arch or horseshoe form, would seem to be sufficient evidence that such a form possesses some peculiar advantages as applied to carbonizsd fibrous material. In fact, Professor Brackett himself admits in his answer to question 34, that the form does possess an advantage in connection with a long, thin conductor of carbonized fibrous material. Now it seems clear that whatever advantage may exist in this case, must exist, at least to some extent, in any conductor of the same form whatever its length or thickness, and I do not think there can be the slightest doubt that such advantage does actually exist in an arch-shaped conductor of the dimensions shown in the patent, or of any other dimensions.

Professor Barker in his answer to Q. 9, folio 2123, concurs with the opinion of Professor Brackett that there is no novelty in the subject-matter set forth in the patent, this opinion being based upon the same assumption, namely, that "carbonized fibrous material was used in the said incandescent lamps, or was described for such use either in the form of straight pencils, or in the form of arch or equivalent shapes." In answer to X Q. 53, 54 and 55, Professor Barker selects the English patents of Roberts and of Konn as equally complete and satisfactory anticipations of the first claim of the patent in suit. The patent of Roberts, speaks generally of a conductor made of charcoal, but as the term charcoal was commonly used in the art of electric lighting as it existed at that day, to denominate carbon of any sort, especially gas carbon, it does not seem to me that it would serve to direct attention to such a material as is clearly contemplated in the patent in suit. In his description of his invention, Roberts systematically uses the word "graphite," which may mean the mineral known as plumbago, or may mean gas carbon. It certainly does not mean carbonized fibrous material. As
2265 Professor Barker admits, the drawing shows the conductor in the form of a straight bar or strip, and he then makes the assumption, in which I entirely disagree with him, that "inasmuch as the advantages set forth in the patent in suit as belonging to the arch form of incandescent conductor, seem to me to be secured to the same extent by the form of said conductor shown in the Roberts patent," he thinks it is substantially equivalent for the conductor described in the first claim of the patent.

It does not seem to me to require any argument to show that a fragile material of a given thickness mounted between thick supports, would be much more likely to be broken by longitudinal expansion than if it were in the form of an arch or horseshoe, for the simple reason that in the first instance the breaking strain is concentrated at either end close to the supports, while in the latter it is uniformly distributed throughout the whole length.

The patent of Konn shows as incandescing conductor, preferably of graphite, in the form not of an arch, but of a V. It seems hardly necessary to point out that graphite is mineral carbon, that it is expressly distinguished in the patent in suit from the carbon of fibrous material, and that hence it cannot be considered an equivalent for it, nor *nor* can the V-shaped conductor be considered as an equivalent for the arch. It is true that it possesses some of the advantages of the arch in respect to the better distribution of light, greater convenience of construction, arising from the parallelism of the leading-in wires, etc., but on the other hand, it possesses but little if any advantage over the straight form in respect to the uniform distribution throughout its length of the strains caused by the longitudinal expansion and contraction under the variations of temperature. For this reason, I do not think it can be considered an equivalent for the arch in the patent in suit. Moreover in Konn's lamp the incandescent portion is confined to a short space at the angle of the V, which is a wholly different construction from
that contemplated in the patent in suit, and one which would
2266 utterly fail to realize many of the advantages which it was
the object of the patentees in the patent in suit to obtain.

I am unable to find the combination of the second claim in any of the patents and publications cited by Professor Brackett. He says in his answer to cross-question 42 that the English patents of Roberts and of Shepard, and the Lodyguine publication are the ones which he would select as better fulfilling the conditions, and of these he is inclined to regard Roberts as the best. As I have already said, Roberts only uses the word "charcoal" in the most general way, and it is by no means certain that he had carbonized fibrous material in mind at all. The lamp described by Shepard, is not, properly speaking, an incandescent lamp, at all, but is one in which the carbon is intended to be consumed, and the electrode gradually fed forward as required. Charcoal is mentioned as the material in the same general sense that it is in the Roberts patent. The same remark will apply to the description of the Lodyguine lamp. The article in evidence (which is a translation) in referring to the old method says, "The electric spark was passed between two points of charcoal, each attached to a copper wire connected with an electro-magnetic machine." At the date when this was written, 1873, charcoal in the form of carbonized wood had not been used for many years for electric lighting. No one ever thought of using anything but gas carbon or artificially prepared hard carbon, so that the word "charcoal" as there used, unquestionably refers to hard carbon, and it is fair to presume that it means hard carbon in the description of the incandescent lamp. It has always been understood among electricians that what Lodyguine actually used, was a thin pencil of artificially prepared hard carbon. It of course follows that unless carbonized fibrous material was actually intended to be described in these publications and patents they cannot constitute an anticipation of the second claim.

The anticipations of the second claim, cited by Professor Barker, are the same as those cited by Professor Brackett and I do
2267 not find that he gives any additional reasons for regarding
them as containing an incandescent conductor of carbonized fibrous material, such as is set forth as one of the elements of the combination in the second claim of the patent in suit.

In reference to the fourth claim of the patent, in which a carbon made from fibrous or textile material having the form of an arch or loop, is an essential element of the combination, it only seems necessary to say that if this element of the claim is new, the combination is necessarily new also. I do not find that either Professor Brackett or Professor Barker is willing to say that any of the patents and publications contains a description of the entire combination of the fourth claim, and in fact this is expressly admitted by Professor Barker in his answer to X Q. 59. This must necessarily be true, because the fourth claim consists essentially of the subject-matter of the first claim combined with certain additional elements.

197 Q. Defendant's experts express the opinion that the patent in suit does not contain a sufficient description of the character of the fibrous or textile material to be used for the burner, its preparation or carbonization and its carbonization, to enable others generally skilled in the art as it existed at the date of the application, to produce a practically operative incandescent conductor without experiment. Do you agree with them in this?

A. I do not agree with defendant's experts in their respective opinions on this point. The specification states that carbonized paper and wood carbon have been made use of in practicing the invention, and that the carbons are to be made from vegetable fibres or textile material as distinguished from mineral or gas carbon.

I think there can be no doubt that any person reasonably well skilled in the art, would without difficulty have been able, at the date of the patent, to select a suitable quality of paper or of textile material, and to carbonize the same by well-known methods. He would naturally have selected paper or thread of uniform
2268 thickness and of pure material, free from foreign substances,
either of which could be found in the market without the least difficulty. As to wood carbon, it does not appear to me that any description is needed other than the general directions which are given. It is well known at the present date that there are very many kinds of straight and close grained woods from which carbons of a very good quality may be made, and I think a persons skilled in the art would have hit upon some one of these without difficulty. There was no occasion for the patentees to describe, more than they have done, the process of carbonization, for it was just as well understood in 1880 as it is to-day. In my opinion, the patentees, in preparing their specification in accordance with the rules of the Patent Office, which direct that the description shall be devoid of unnecessary prolixity, were undoubtedly right in leaving out a description of the details of the process of carbonization and a catalogue of all the forms of fibrous material which might be more or

less suitable for the purpose. One material, namely, paper, is specifically mentioned, and that, as I understand it, is all that the statute requires. As I have already said, it does not seem to me that the selection of a suitable quality of paper would present any difficulty whatever, as there are many kinds of paper in the market which would infallibly suggest themselves as being well adapted to the purpose.

198 Q. Do you agree with the opinions expressed by defendant's experts in regard to the materiality or effect of the amendments made in the application for the patent in suit, while the same was pending in the Patent Office, and the differences between the application as originally filed and the patent as finally issued?

A. I do not agree with the opinions of defendant's experts as to the effect of the amendments referred to. I am unable to find any invention whatever which is described and claimed in the patent, which was not described in the application as originally filed. Defendant's experts appear to lay much stress on the omission in the final specification of the words "ordinary gas carbon." The omission 2269 of these words certainly does not extend the scope of the patent, but on the contrary restricts it. They also take the ground that the omission of the word "charcoal" which appears in the original specification, in some way alters the scope of the patent and tends to expand it. My opinion is substantially that of complainant's expert, Professor Cross, namely, that the word charcoal had been so loosely used in the art that it had wholly lost any definite meaning. It might have meant almost anything, including gas carbon and other substances expressly intended to be excluded from the scope of the invention. The cancellation of the word removed what I consider to have been a misleading and therefore objectionable ambiguity. The omission of the words "covered with powdered plumbago" used in connection with the carbonized paper has very much the same effect. It was not an essential part of the process of preparing the carbon and it was vague and obscure, inasmuch as it did not state clearly how the application was to be made. As to the matter which was inserted in the amendment in reference to the sealing of the electrodes and the advantages of the arch form of carbon, I am unable to see that the scope of the patent was in the least changed by their insertion. The first is merely a statement pointing out that certain processes may be used. These processes were old and any one had a right to use them so far as this patent is concerned, whether they were pointed out or not. As to the advantages of the arch form, they were inherent in the thing itself when constructed according to the original specification, and were afterwards neither more or less so because they were specifically pointed out. It is well understood that a patentee is entitled to the benefit of all the advantages necessarily arising from his invention, whether he knew them or not. Referring to the statement of Professor Barker in his answer to Q. 42, that in the original application the patentees expressed no preference for carbonized fibrous or textile material over other forms of carbon mentioned, I would

2270 say that in the fourth claim an incandescent conductor made of carbonized fibrous or textile material is claimed most specifically, and no other kind of carbon than fibrous or textile carbon is specifically referred to in any of the claims.

I wish to state here, lest the stat-ment I have just made may appear to be in contradiction to that made in my answer to X Q. 130, of my testimony in the *prima facia* case, that in making this last-mentioned answer I did so after examination of a printed copy of the original specification in which examination I overlooked the fourth claim, which was printed on the other side of the leaf, and hence my answer was made without reference to the fourth claim. Had I been aware of it my answer then would have been to the same effect as now.

My opinion is that the changes made in the specification were not only permissible, but were in accordance with good practice, and with the rules of the Patent Office, which expressly say that the specification shall be free from ambiguity and from unnecessary prolixity. The statement of the advantages of the arch form, while not required by the rules adds nothing whatever to the scope of the invention, but merely serves to indicate to the examiner and to any person reading the patent, some of the points wherein it differs from prior inventions of the same kind, all of which differences, however, as well as advantages, would be obvious to any person upon careful consideration of the invention.

The most essential and important part of the invention which is claimed by the patentees of the patent in suit as new, is the incandescent conductor of carbonized fibrous or textile material, and of an arch or horseshoe shape, and this is exactly the invention, neither more nor less, which was claimed in the fourth claim of the original specification in these words, to wit:

"An incandescing arc made of carbonized fibrous or textile material."

2271 The presence of this claim in the original specification is sufficient evidence that the inventors had the invention and that they intended to claim it as new. It seems to me, therefore, that the amendment of the specification in the direction of more fully and more distinctly describing and setting forth the invention claimed, was not only permissible, but was obligatory upon the patentees in order to comply with the statute and with the rules of the Patent Office, that the thing claimed shall be sufficiently described in the specification so that the meaning of the claim may be understood.

199 Q. Do you agree with the opinions expressed by defendant's experts, that the lamp structure shown and described in the patent in suit has such serious defects that it would be wholly unsuitable for practical use in electric illumination, and that it would not be superior to those described in the prior patents of Roberts, Shepard, Konn, Kosloff and others in evidence?

A. I think the defendant's experts are in error in this particular, an error perhaps arising largely from the fact that they lay down certain arbitrary standards of comparison with modern and improved lamps, which have been undergoing constant improvement for the last eight years; for example, Professor Brackett says in substance that a practically useful lamp should have a lifetime of 1,000 hours. I do not know of any manufacturer at the present time who will undertake to warrant lamps to last that length of time. It is only within two or three years that the manufacture has been so perfected that an average lifetime of four to six hundred hours could be depended upon. Mr. Edison lays down, as an essential requirement that it should be able to compete commercially with gas, but I know of no reason why such an arbitrary standard should be fixed upon. There are many applications which might be made of incandescent lamps in which a gas-light could not be used at all, or in which the first cost of the lamp or the length of its life would be of comparatively small importance, such for example as the lighting of mines filled with explosive gases; the lighting of powder magazines, of submarine caissons and other applications of like nature.

2272 In my answer to X Q. 26, in my testimony given in behalf of complainant in the *prima facia* case, I said that I considered it doubtful if so high a vacuum as that in defendant's lamp could be preserved with the structure of the enclosing glass chamber described in complainant's patent in suit and in their prior patent No. 205,144. Again in answer to X Q. 46, I said:

"I should regard it as quite doubtful whether a perfect vacuum could be maintained in a chamber having the construction described and shown in this patent, but I am not willing to go so far as to say that it is impossible."

This statement was made from an examination of the drawings of the patent and in the absence of any experimental knowledge as to the efficiency of the structure in maintaining a high vacuum. Since giving the testimony above quoted, I have examined a considerable number of lamps made in accordance with the drawings and specifications of complainant's patent, and in view of the results which have been obtained, I am even more strongly confirmed in my original opinion not only that an incandescent lamp may be made in accordance with the description of the patent which would have a sufficiently long life to be of value for many practical purposes, but that it would be a practically useful commercial incandescent lamp for ordinary purposes, and would be immeasurably superior to any of those which are described in the prior patents and publications referred to in the question.

Adjourned to 2.30 p. m., April 25th, 1889.

New York, *April 25th*, 1889—2.30 p. m.

Met pursuant to adjournment.
Present: Counsel as before.

200 Q. In your answer to Q. 197 you refer to the use of 2273 the term "charcoal" in the art of electric lighting, as it existed at the date of various prior patents and publications, put in evidence by defendant to denominate carbon of any sort.

Do you refer to the use of the term "charcoal" in the sense set forth by Professor Cross and Dr. Morton in their depositions in this case, and do you agree with them in the opinions they express on this point?

A. I entirely agree with the opinions of Professor Cross and Dr. Morton in respect to the meaning of the term "charcoal" in the art of electric lighting. The greatest confusion exists in all the literature relating to the subject as to the respective meaning of the terms "charcoal," "carbon" and "graphite." It is easy to see how this confusion has arisen. It is due to the fact that electrodes of wood charcoal were first used and for many years. Then it was discovered that gas carbon and graphite were preferable forms of carbon for producing the arc, but they still continued to go by the name of charcoal, just as the plumbago in the modern lead pencil continues to go by the name of lead. Since this point was raised I have examined a portion of the many works referring to the subject, and will quote a few extracts simply to illustrate the exceedingly loose and indefinite manner in which the term charcoal is used even in the standard literature of the subject which is always considered to be more accurate in the use of such terms than are the specifications of patents.

Elements of Chemistry, by W. A. Miller, New York, 1864, in describing the electric arc, refers to the electrodes repeatedly on page 414, as being of "charcoal." On pages 415 and 416 it speaks of "coke" and "gas coke." In the foot-note on page 415 is a description of the Duboscq lamp, in which the electrodes are called "charcoal points," although it is well known that charcoal was never used in this lamp, but on the contrary pencils of gas carbon either sawed out from solid blocks or moulded and baked.

2274 Prof. Faraday in his lectures on the Forces of Matter, published by Griffin & Company, London, 1860, page 165, in describing the electric light, says:

"I will first of all show you the image of the charcoal points on the screen and draw your attention to the spot where the light is produced. There are the coal points. The two carbons are brought within a certain distance; the electricity is being urged across by the voltaic battery, and the coal points are brought into an intense state of ignition."

Here we have the same electrodes spoken of as "charcoal, "coal" and "carbon" by Professor Faraday all in the same breath in an explanation of the construction of a light-house lamp, in which nothing but gas carbon ever has been or ever could be used.

Atkinson's translation of Ganot's Physics, Baillaire, publisher, London, 1863, page 61, describing the electric arc, repeatedly refers to the electrodes on pages 630 and 631 as having been produced with "charcoal," and with "light-wood charcoal." On page 632 it is said:

"At present the electrodes are made of gas graphite, a modification of charcoal, deposited in gas retorts; this is hard and compact, and only burns slowly in air."

On pages 633 and 634 the Duboscq lamp is again described and the carbon pencils are repeatedly referred to as "charcoals."

Here we have retort carbon described as a "modification of charcoal" and called "graphite;" this, too, in a standard text book of the very highest authority.

J. Muller, Principles of Physics, etc., Baillaire, publisher, London, 1847, page 376.

"If we fasten to each of the poles of a galvanic circuit pointed pieces of carbon (of the kind and size used in the carbon cylinders of Bunsen's battery), we shall, as soon as these points come into contact, perceive an uncommonly glittering light. This bright light can be seen by a Bunson battery of only four elements
2275 brightly, a small, luminous star appearing where the points of the charcoal come into contact with each other. By increasing the number of elements the splendor of the appearance considerably increases; and thus, in a circuit consisting of from thirty to fifty elements we may obtain a light far exceeding in brightness Drummond's hydro-oxygen light. By the application of this number of pairs of plates we may remove the points of the pieces of carbon tolerably far from each other, if only the current passes, and we may thus obtain a splendid bow of light formed by the glowing particles of the charcoal which pass from one pole to the other."

It is certain that this extract refers to hard or gas carbon, because no other kind is ever used in Bunsen's batteries, and yet we find it indiscriminately referred to as "charcoal" and "carbon" throughout the whole paragraph.

Pynchon's Chemical Physics, New York, 1872, page 344. In describing the electric light the author says:

"When pieces of well-burned charcoal are attached to the wires and become the poles of the battery, on bringing them near each other a most brilliant arc of flame, emitting the brightest artificial light known, flashes between them. The compact coke of gas retorts is better adapted to this purpose than any other form of charcoal. * * * * If the two carbon points are arranged in a horizontal position at right angles to the magnetic meridian," etc.

Here we have in another standard text book gas-retort "coke" called a "form of charcoal" and referred to as "carbons." In question 356, page 345 the inquiry is made:

"What change takes place in the length of the charcoal points during the passage of the current?" and the answer is "There is a considerable transport of the particles of carbon from the positive to the negative pole."

2276 Pepper's Science Simplified, London and New York. This work has no date, but I had a copy of it in my possession as early as 1874. On page 347 in a description of the Serrin regulator, in which no form of carbon is ever used other than moulded gas carbons, the electrodes are referred to almost in the same breath as "carbon points" and as "charcoal points."

It would probably not be difficult to find many other similar instances of the vague and ambiguous use of the word charcoal in the literature of electric lighting between 1847 and 1875, but those which I have cited are, I think, more than enough to show beyond question that the use of the term "charcoal" in the early specifications, as for example, that of Roberts, is much more likely to have meant gas carbon, coke or graphite, than wood carbon. It is at all events certain that its meaning could not have been confined to wood carbon, nor could it have excluded any other form of carbon of a mineral nature applicable to electric lighting. The extracts which I have cited also show, that the cancellation of the word charcoal in the original specification of the patent in suit, removed an exceedingly ambiguous term and was therefore in the direction of good practice, as I stated in my former answer.

201 Q. Have you read the testimony given in this suit on behalf of the complainant, by Professor Cross and Dr. Morton, and do you agree with them in the statements they make and the opinions they express?

A. I have read the testimony of Professor Cross and also that of Dr. Morton, and in my previous answers I have pointed out several important particulars wherein I concur with them and have given my reasons at length upon which such concurrence was founded. In answer to the question I can only say that in respect to matters not specifically referred to in my former answers I find no reason to dissent from the opinion which they have expressed, either separately or in concurrence, but on the contrary, fully agree with them in every essential particular.

2277 Complainant's counsel offers in evidence the title page and sections 677, 678 and 679, on pages 630 to 635 of Ganot's Physics, published at London in 1863, and the same is marked "Complainant's Exhibit Extract from Ganot's Physics;" also the title page and a part of page 376 of Muller's Physics and Meteorology, published at London in 1847, and the same is marked "Complainant's Exhibit Extract from Muller's Physics;"

Also the title page and parts of pages 413, 414 and 416 of Miller's Chemical Physics, published at New York in 1864, which is marked "Complainant's Exhibit Extract from Miller's Chemical Physics;"

Also parts of pages 335, 336, 345, 346 and 347 of Cyclopaedic Science Simplified, by J. H. Pepper, which is marked "Complainant's Exhibit Extract from Pepper's Cyclopaedic Science;"

Also an extract from Faraday's Lectures on the Physical Forces, published at London and Glasgow in 1860, part of pages 165 and 166, which is marked "Complainant's Exhibit Extract from Faraday's Lectures;"

Also section 355, on pages 344 and 345, of Pynchon's Introduction to Chemical Physics, published at New York, in 1877, which is marked "Complainant's Exhibit Extract from Pynchon's Chemical Physics;"

Defendant's counsel admits that the various books referred to were published and circulated at the dates mentioned on their title pages, and consents that copies of the parts offered in evidence may be used in place of the original books, subject to the correction of any errors that may be found therein.

Adjourned to April 26th, at 10.30.

The examination of Mr. POPE is continued on page —.

2278 NEW YORK, *April* 15, 1889—3 p. m.

Met pursuant to agreement.

Present: Thomas B. Kerr, of counsel of complainant, and Walter K. Griffin, of counsel for defendant.

Testimony of John M. Robertson.

JOHN M. ROBERTSON, a witness on the part of the complainant, being sworn, testifies as follows in reply to interrogatories by Mr. KERR:

1 Q. State your name, age, residence and occupation.

A. John M. Robertson, 40 years old. I am superintendent of the Sawyer-Man Electric Company and reside in New York.

2 Q. Were you ever in the employment of the Consolidated Electric Light Company, and if so, state when you first went into its employment and how long you continued?

A. I went into the employment of the Consolidated Company early in the spring of 1885 as superintendent of its factory, which was then located in Brooklyn at Adams and Front streets, and I continued until the first of October, 1888. Since then I have carried on the same factory, which is now being operated by the Sawyer-Man Electric Company.

3 Q. Do you know Henry E. Vineing, and if so, please state when and where you became acquainted with him?

A. Yes, I know a man by the name of Henry E. Vineing and became acquainted with him in the summer of '85, when he was employed by the then general manager of the Consolidated Electric Light Company to work under me at the Brooklyn factory.

4 Q. State what Vineing was employed to do and the circumstances under which his connection with the company terminated.

2279 A. Vineing was employed, as I understand, because it was supposed that he would make a good foreman in charge of the manufacturing of incandescent electric lamps, and he was put in charge of that department. The company at that time was manufacturing dynamos and other electric appliances. At that time the company was also increasing the capacity of the lamp department and Vineing was supposed to be a capable man for looking after additional apparatus, and so on, in this department. Also, at this time the company were having made, under direction of the legal department, experiments in baking and treating various materials for making carbons and Vineing had charge of this work. He looked after the baking of the carbons personally. He remained with us until the fall of the same year when we moved the factory to Park avenue and to more commodious quarters. I had found by this time that Vineing was entirely incapable of acting as foreman of the lamp manufacturing. While a capable man for any particular job that he was put upon, he was entirely unreliable in carrying out the whole work and in managing those under him. He was never willing to let well enough alone, but always was experimenting without asking permission or giving any notice to the superintendent that he was making such experiments and in this manner he frequently did very bad work which would show itself by bad lamps being produced. When we started to fix up the new factory he became very slack in his work, and we were on the eve of discharging him when he gave me a letter to Mr. Davis, who had employed him, stating that he had better offers from other companies and unless he was paid more money he would have to leave the services of the company. Mr. Davis said that the matter was entirely in my hands, so I told Vineing that he had better take the offers made him by the other parties, especially as he had not given satisfaction. He then left.

JNO. M. ROBERTSON.

2280 New York, *April 9th*, 1889.

Met pursuant to notice.

Present: Amos Broadnax, Esq., for complainant, and Grosvenor P. Lowrey, Esq., for defendant.

Complainant's counsel accepting the proffer of defendant's counsel; counsel stipulates that the testimony of Wm. H. Church taken in the interference between Sawyer & Man and Thomas A. Edison, as found in the certified copy of such testimony, said testimony to be copied into this record, and made a part hereof, substantially the same to all intents and purposes, as if the same had been taken in this case, said Church being called as a witness and subject to further examination and cross-examination, to all matters pertaining to the subject-matter of said testimony.

Testimony of William H. Church.

William H. Church, being called on behalf of complainant herein and duly sworn, testifies as follows:

1 Q. What is your name, age, residence and occupation?

A. William H. Church, about 57 years of age, I reside in the city of New York, I am in no regularly established business, I am taking care of my own property.

2 Q. Are you the same William H. Church that testified on the 15th of March, 1881, in the interference between Wm. E. Sawyer and Albon Man on the one side, and Thomas A. Edison on the other, and also on September 22 and the 11th of November, 1882?

A. I am.

3 Q. I place in your hands a certified copy of your testimony as taken in that interference. Please to look at it and state between what pages you find that testimony.

A. The first deposition is paged 25 to 43 inclusive, the seco[illegible]d is on pages 84 to 100 inclusive, and the third deposition is in the s[illegible]plemental record, pages 63 to 76 inclusive.

2281 4 Q. State, if you please, how recently you have read these depositions?

A. Within the last week.

5 Q. If the same questions contained in these depositions, were asked you now, would you make the same answers to them?

A. I would.

The examiner is requested at this point to copy into this record the depositions referred to as a part of the testimony of the witness in this case as provided in the foregoing stipulation.

COUNSEL'S NOTE.—The depositions of Wm. H. Church, taken in the interference case and referred to above are printed in vol. 3 of this record as follows:

First deposition, vol. 3, p. 125–143.
Second deposition, vol. 3, p. 187–204.
Third deposition, vol. 3, p. 601–613.

6 Q. State, if you know, who did the carbonizing for Sawyer & Man, at their shop, corner of Elm and Walker streets?

A. Edwin L. Myers.

7 Q. Did he do it all?

A. All that he did was under the direction of Sawyer & Man, and he attended to it personally, and he did most of it.

8 Q. State if you know what material he carbonized there for the incandescing conductors of the lamps.

A. There was paper and willow twigs, and bamboo—strips of bamboo and other woods that I don't know the names of. They were trying different things all the while.

9 Q. What was the form and the size of the bamboo and different kinds of wood that Mr. Myers carbonized there in addition to the paper, about which you have testified?

2282 A. I can't give the size. They were small strips of bamboo and of other woods.

10 Q. How did you know that Mr. Myers was making carbons from bamboo?

A. I saw the pieces on his bench.

11 Q. What was the form of the pieces?

A. They were small, straight pieces.

12 Q. Made from a bamboo fishing rod?

A. That is what I supposed, and Myers told me so.

13 Q. How often did you see them carbonizing bamboo and willow twigs?

A. I saw Mr. Myers working upon these things nearly every day for about two months, as I recollect it.

14 Q. State if you know whether any of these carbons were used in the lamps?

A. I don't know from having seen them put in the lamps, but

McKeesport L. Co.
Complainants Exhibit Rockwell Kent Letter
April 9 1889
W.J.J.
S.E.

Friday night they
all came. They were
shown Sawyer man straight
pencil lamp; horseshoe
lamp & new Feeder lamp
which I was at work
on & told all about
carbonizing fibre re.
Got Edison Some
[illegible] on this.

No. 286.
C. E. Light Co.
v.
McK. Light Co.
p. 2283

was shown them after they were put in, and told by Mr. Myers that he had made them.

15 Q. How does it happen that when you testified in the interference case, you did not mention these bamboo and willow carbons?

A. I was only asked about paper, and as I understood then there was no question except as to the carbonization of paper.

16 Q. State if you recollect of an exhibition being given of the Sawyer-Man lamps in the Walker-street shop in the spring of 1879?

A. I do.

17 Q. At what time in the spring was it that that exhibition was given?

A. On the evening of March 28th, 1879.

18 Q. State, if you know, how that exhibition came to be given?

A. Mr. Sawyer wanted to sell a controlling interest in the Electro Dynamic Light Co. to the Edison Company, or to parties interested in that company, and in view of that he asked me to call
2284 upon Mr. G. P. Lowrey and see if I could bring about the
sale of the stock. I accordingly called on Mr. Lowrey, and made an appointment with him to come and see an exhibition of the lamp, and to bring his friends. He did not state to me who they would be. I think I called twice upon Mr. Lowrey. I think in one instance Mr. Sawyer was with me, but of this I cannot be certain. The result of our interviews with Mr. Lowrey was a letter from him to me, appointing a time when he would come and see the lamps. That letter is dated the 26th of March, 1879, and at the time appointed in the letter Mr. Lowrey and some of his friends came to witness an exhibition of the lamps.

19 Q. Can you produce that letter?

A. Yes, sir.

20 Q. Please do so.

A. Here it is.

(Witness produces a letter.)

21 Q. By whom does that letter purport to be written?

A. Rockwell Kent.

Letter offered in evidence and marked Complainant's Exhibit Rockwell Kent Letter, April 9th, 1889. Objected to as hearsay, as not competent evidence of the truth of the facts in said memorandum stated.

(Here follows lithograph marked p. 2283.)

22 Q. Was the exhibition of the lamps made at the time appointed in the letter?

A. It was.

23 Q. Do you find a memorandum in lead pencil written on the back of the letter?

A. I do.

24 Q. Please to read the letter and also the memorandum, so that the examiner may copy it into the record?

Witness reads as follows:

> "Friday night they all came. They were shown Sawyer-Man straight-pencil lamp, horseshoe lamp and a new feeder lamp 2285 which I was at work on and told all about carbonizing fibre, etc. Ask Edison some ? ? on this."

25 Q. In whose handwriting is that memorandum?

A. Wm. E. Sawyer's.

26 Q. Who was present at that exhibition?

A. Mr. G. P. Lowery, E. N. Dickerson, Mr. Wright, Mr. Goddard, Mr. Galloway, and myself. Mr. Sawyer was present.

27 Q. Is that all you recollect of being present?

A. Yes, I think so.

28 Q. Was Mr. Man present?

A. No.

29 Q. This letter which you have produced is addressed to you. Was it received by you personally, on or about the day of the date?

A. It was.

30 Q. Have you any memorandum made by you at the time of the proposition you made to Mr. Lowery for the purchase of a controlling interest in the Electro-Dynamic Light Company?

A. I have.

31 Q. Please to produce it.

A. I now do so.

32 Q. In what is that memorandum contained?

A. In a diary that I carried for the year 1879.

33 Q. Please to read the memorandum out of the diary produced by you, so that the examiner can copy it in the record.

A. Under date of Saturday, March 29, I read as follows:

"I called on Mr. Lowrey this morning. I made a proposition. His party to purchase"——

I am not certain whether the figures as written are $10,000 or $100,000.

"—of our stock and then to purchase enough of the treasury stock at 50 per cent. to control our company."

2286 34 Q. When you say "our company" in the memorandum, what do you mean?

A. The Electro-Dynamic Light Company.

Mr. Broadnax, counsel for complainant, here states upon the record, that the Exhibit Rockwell Kent Letter with the endorsement on the back in the handwriting of Mr. Sawyer, was given to him by Mr. Sawyer to be used in evidence in the interference between Edison and Sawyer and Man. Said letter was received by Mr. Broadnax almost immediately as he recollects it now, after the testimony was closed for Sawyer and Man and too late to be used by him in evidence; which said testimony was closed on or about the 23d day of September, 1881, that said letter and the endorsement in Sawyer's handwriting is exactly as it was when received by Mr. Broadnax and has been in his possession ever since.

Mr. Broadnax here agrees to have said letter and endorsement photo-lithographed to be used on the hearing of this case.

35 Q. State, if you please, whether the extract read by you to the examiner from your diary and by him copied into the record is an exact copy of the memorandum found in your diary.

A. It is.

36 Q. Was it made on the day of its date?

A. It was, which was Saturday, March 29th, 1879.

37 Q. These gentlemen that appeared to witness the exhibition in March, 1879, whom did you understand them to represent?

A. Parties interested in the Edison Company.

The examination of Mr. Church is adjourned till Monday, April 15th, 1889, at 11 a. m.

2287 NEW YORK, MONDAY, *April 15th*, 1889.

Met pursuant to adjournment.

Present: Counsel as before.

Direct examination of WM. H. CHURCH continued:

38 Q. You have stated that Mr. Man was not present at the exhibition in the Walker and Elm street shop on Friday evening, March 28th, 1879; state if you know why he was not present at that exhibition.

A. Because Mr. Man and Mr. Sawyer had disagreed in relation to the construction of their lamp. Mr. Sawyer claimed that what he called a feeder lamp would do better than the lamp they had been making, known as the Sawyer-Man lamp. Mr. Man had discontinued working with Mr. Sawyer altogether and would have nothing to do with the feeder lamp. Mr. Man had no knowledge of this exhibition at the time.

39 Q. Did you never measure the size and length of the bamboo and willow carbons you saw Mr. Myers making at the Walker and Elm street shop?

A. No, sir.

40 Q. Please to give the size and length of such carbons as nearly as you can judge and give also the form of them as nearly as you can recollect.

A. In size and length I should judge they were from one to six inches in length and were about the size of a broom-corn whisp; in form they were in straight pencil and in arch or loop form.

41 Q. At the time of the exhibit on the evening of March 28, 1879, how long did Mr. Lowrie and his friends remain there to witness the exhibition?

A. They arrived there about half past seven and remained there till about ten, as nearly as I can recollect.

42 Q. Were the lamps burning all the time?

A. Yes, sir, they were.

43 Q. How many lamps were there in circuit?

2288 A. Seven or eight.

44 Q. Who was Mr. Rockwell Kent, the person whose name is signed to the letter you have produced making the appoint-

ment for Mr. Lowrie and his friends to witness the exhibition on March 28th, 1879?

A. I don't know Mr. Rockwell Kent personally, but this letter was written in accordance with a promise made by Mr. Lowrie to myself, which promise was duly kept, and as this letter was written on one of their letter-heads I presume that Mr. Rockwell Kent was in some way connected with their office.

Cross-examination by W. K. GRIFFIN, Esq.:

42 X Q. In what other Sawyer-Man interferences have you testified other than the Sawyer and Man-Edison interference?

A. I do not recollect of any.

46 X Q. Did you not testify in the Sawyer and Man-Weston interference as to treating carbons?

A. Possibly.

47 X Q. Did you not testify in the Sawyer and Man-Maxim interferences?

A. I may have testified in those, I knew of them.

48 X Q. And you can't say whether you testif*y* in the Weston interference or not?

A. I cannot say positively.

49 X Q. When did you first become connected with the United States Electric Company?

A. About the time of its organization or soon after, about 1880 I should think.

50 X Q. How did you first become connected with the company?

A. I was employed to sell plants for electric lighting.

51 X Q. How did you come to go with them?

A. I was sent for by them.

2289 52 X Q. How long did you remain in their employment?

A. Quite a while, I can't remember exactly.

53 X Q. What is your best recollection?

A. Well I think I went into their employ in 1880, and left them in the winter of 1881, toward the spring. I am not quite sure.

54 X Q. Did you then know Mr. Curtis, the attorney for that company?

A. I did.

55 X Q. Did you not, in 1880, bring to Mr. Curtis' attention a certain agreement made between Mr. Sawyer and Mr. Flanagan, dated January 2, 1877, whereby Sawyer assigned three-fifths interest in certain patents and inventions to Mr. Flanagan?

Complainant's counsel objects to the question as not cross-examination and as not competent, pertinent and material in any aspect of the case and unless counsel shows upon the record that the question calls for something that is competent, material or relevant, complainant's counsel instructs the witness not to answer.

Defendant's counsel states that the materiality and relevancy of the question will fully appear as the cross-examination proceeds.

Complainant's counsel says in response that the question is not cross-examination, and that if he persists in examining witness upon matters not named in the examination-in-chief he makes the witness his own, and is responsible for what he testifies to, and complainant's counsel will claim the right to cross-examine him on such matters, and further that in the event that the relevancy, pertinency and competency of the questions does not appear by the examination he will move to strike out the whole of the so-called cross-examination.

2290 A. I don't think I did as early as 1880.

56 X Q. When did you do so?

Same objections and notice.

A. Some time after 1880 as I recollect.

— Q. Was it before or after you left the employment of the United States Electric Company?

Same objections and notice.

A. Oh, after.

58 X Q. Who represented the interest of Mr. Flanagan at that time?

Same objections and notice.

A. I think Mr. Schuyler always represented Mr. Flanagan's interest.

59 X Q. Why do you say you think; do you not know?

Same objections and notice.

A. I do not know positively.

60 X Q. Did you not act for Mr. Schuyler?

Same objections and notice.

A. Subsequently I did.

61 X Q. In trying to dispose of the Flanagan rights?

Same objections and notice.

A. I did, yes.

62 X Q. Were not certain drawings relating to those Flanagan rights in the possession of Mr. Schuyler?

Same objections and notice.

A. They were.

63 X Q. Mr. Schuyler's office at that time was in Nassau St., was it not?

Same objections and notice.

A. I think it was in Cedar, near Nassau, and then he moved round into Nassau street.

64 X Q. When did you first become acquainted with Mr. Richard N. Dyer, now one of the attorneys for the Edison Company and also of counsel for the defendant?

Same objections and notice.

A. I think it was in 1881.

65 X Q. When did you first become acquainted with Mr. Tomlinson, attorney for the Edison Company? 2291

Same objections and notice.

A. I was introduced to Mr. Tomlinson on the occasion of Mr. Evarts' argument before Judge Wallace in the New York case.

66 X Q. You were present to hear the arguments in court, is that so?

Same objections and notice.

A. Yes, sir.

67 X Q. Early in 1887 did you not go to see Mr. Dyer at his office 40 Wall St., New York city?

Same objections and notice.

A. I think I did in 1887.

68 X Q. Did you not see Mr. Dyer?

Same objections and notice.

A. I did.

69 X Q. Were you not by him introduced or reintroduced to Mr. Tomlinson?

Same objections and notice.

A. I do not remember; I may have been.

70 X Q. When you went to the office, 40 Wall street, the first time did you not see Mr. Dyer, and subsequently as part of the same interview, Mr. Dyer and Mr. Tomlinson together?

Same objections and notice.

A. I think I did.

71 X Q. Did you not tell them substantially that you were in possession of some important information as to the Sawyer and Man patent in suit?

Same objections and notice.

A. Well, I don't understand what you mean by "information." If you will be a little more explicit as to what you mean by information I will be able to answer your question; I have no objection to telling you the precise motive in seeing Messrs. Dyer and Tomlinson in relation to the Flanagan contract.

72 X Q. You spoke to them then about the Flanagan contract?

2292 & 2293 Same objections and notice.

A. I did.

73 X Q. What did you tell them as to that contract?

Same objections and notice.

A. I requested them to consider a proposition to purchase Mr. Flanagan's three-fifths interest in the contract between himself and

Mr. Sawyer in order that they might have the right to use the same if they should think it wise to do so in their own interest.

74 X Q. Did you not tell them substantially that you were in possession of information which would show that the patent in suit was entirely invalid?

Same objections and notice.

A. No, sir; and it was for that very reason that they declined to consider the proposition.

75 X Q. Did you not tell them that you were in possession of information which would show that so far as any invention had been made, it was the sole invention of Mr. Sawyer?

Same objections and notice.

A. Prior to 1878, before Mr. Man and Mr. Sawyer came together.

76 X Q. Did you not inform them that you were in possession of information which would show that the invention of the Sawyer and Man patent in suit was made by Mr. Sawyer prior to his association with Mr. Man?

Same objections and notice.

A. I do not remember that I did.

77 X Q. Will you swear that you did not?

Same objections and notice.

A. To the best of my recollection I did not. I do not see how I could from what was represented to have been done under the Flanagan contract.

Complainant's counsel calls witness's attention to the fact that the questions related especially to the inventions of the patent in suit.

2294 78 X Q. After hearing the statement of your counsel, do you wish to alter your previous answers?

Same objections and notice.

A. No, sir.

79 X Q. Did you not state to them that the contract between Sawyer and Man dated May 11th, 1878, by which Sawyer and Man were stated or believed to be joint inventors was made by Mr. Man so as to defraud Mr. Flanagan of his interest in the Sawyer invention which Mr. Man knew at that time to have been perfected?

Same objections and notice.

A. Before they came together in January, 1878, not at the time of May 11, 1878, as Mr. Sawyer and Mr. Man had been working together since the first of March, 1878.

80 X Q. Did you not tell them that Mr. Man when he was shown the Flanagan contract after his association with Mr. Sawyer, said

that the only way to get over the Sawyer obligation to Flanagan was by Man and Sawyer taking out inventions jointly?

Same objections and notice.

A. Mr. Man refused to go on with the construction of an electric lamp unless Sawyer and he should take out patents therefor jointly as under the Flanagan contract which had terminated in February, he thought that Mr. Flanagan might claim some rights. Mr. Man had not seen the Flanagan contract until about the 11th of May, 1878.

81 X Q. Now will you kindly answer my last question?

Same objections and notice.

A. Yes, as stated above.

82 X Q. Did you not tell them that Mr. Man in your presence, when he was shown the Flanagan contract, said the only way to get over that was by Man and Sawyer taking out joint patents?

Same objections and notice.

A. Mr. Man refused to continue; I think I did tell them practically that.

2295 83 X Q. Did you not state to them that some of these matters you were able to prove by drawings and papers in the possession of Mr. Schuyler?

Same objections and notice.

A. I think I did.

84 X Q. Did you not meet them at Mr. Schuyler's office and did not Mr. Schuyler produce photographs of these alleged drawings?

Same objections and notice.

A. Yes, sir, I did, and Mr. Schuyler produced the original drawings and photographs of them.

Adjourned to Tuesday April 16, 1889, at 11 a. m.

NEW YORK, *April* 16, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and the witness Mr. Church and after waiting fifty minutes and no one appearing for defendant the examination was adjourned till Wednesday, 17th inst., at 11 o'clock a. m.

NEW YORK, *April* 17, 1889.

Met pursuant to adjournment.

Present: Mr. Broadnax for complainant and the witness, no one appearing for defendant and the complainant's counsel states that he has received no notice from defendant's counsel of his desire to further cross-examine the witness; he therefore takes it for granted that he has closed his cross-examination and proceeds with the redirect without waiving objections.

Redirect examination:

2296 85 R. D. Q. You have related upon your cross-examination something about an interview between yourself and Messrs. Tomlinson and Dyer, defendant's counsel; what was your object in calling upon these gentlemen at the time you did in 1887?

A. My object was to sell them the interest under the Flanagan contract.

86 R. D. Q. At whose instigation did you do that?

A. At the request of Mr. S. D. Schuyler.

87 R. D. Q. What price did Mr. Schuyler fix upon for the interest covered by the Flanagan contract?

A. About sixty thousand dollars.

88 R. D. Q. What portion of that was he to give you in the event of your succeeding in selling the contract?

A. One-third of whatever might be obtained. |

89 R. D. Q. And as I understand you Mr. Tomlinson and Mr. Dyer declined to purchase it?

A. That is so.

90 R. D. Q. Either for themselves or for the Edison Company?

A. That is so.

91 R. D. Q. What reason did they give for declining to purchase it, after seeing the papers and drawings pertaining to it in the possession of Mr. Schuyler?

A. That it was of no value to them or to the Edison Company.

92 R. D. Q. Did you offer to sell this same contract or the interest covered by it to any one else and if so to whom?

A. Yes, I first offered it to the Consolidated Electric Light Company, the complainant here, and they declined to purchase it for the same reason. I then presented it to Mr. Curtis of the United States Electric Light Company and he declined to purchase it for the same reason, that it would be of no value to them.

93 R. D. Q. Upon what did you predicate your statement to Messrs. Tomlinson and Dyer mentioned on your cross-examination?

2297 A. On the papers pertaining to the Flanagan contract in the possession of Mr. Schuyler, which they examined.

94 R. D. Q. And any other statement which you may have made to them as I understand you were merely in support of your effort to sell the contract, acting as negotiator for Mr. Schuyler?

A. Yes, sir.

95 R. D. Q. In your interview with Messrs. Tomlinson and Dyer what if anything was said by them to you as to your assisting them in the defence of this case?

A. They said that while there was nothing in the Flanagan contract of any value to them they would like to employ me personally to assist them in the defence of this case and that they would pay me handsomely for my services and they offered me a thousand dollars a day for any time that I might be employed in such service which I declined for the reason that I had already testified in the Sawyer-Man interference on behalf of Sawyer and Man.

Redirect examination closed.

New York, *April* 26, 1889.

Met pursuant to agreement of counsel.

Present: Mr. Broadnax for complainant, and Mr. Griffin for defendant, and the examination of Mr. Church was continued as follows:

Recross-examination of Mr. Church by Mr. Griffin:

96 R. X Q. Did you not at or about the time of your first interview with Mr. Tomlinson and Mr. Dyer leave with them printed copies of the record of the interference between Sawyer and Man, and also copies of agreement between W. E. Sawyer and Albon Man, dated respectively, March 19, and May 11, 1878; and also a copy of an agreement between W. E. Sawyer and Messrs. Smith and Flanagan, dated January 2, 1877.

2298 Objected to as not cross-examination, and not material or competent on any issue in the case.

A. I did not leave with them any printed copies of the testimony taken in the interference, but I left with them written copies of the contracts between Sawyer and Man, and also with Flanagan.

97 R. X Q. Did you not at one of your interviews with them or either of them leave a printed copy of the interference record just mentioned?

A. No, sir.

98 R. X Q. You never left or sent them such a copy?

Same objections.

A. I never had in my possession a copy of that record of interference; therefore, could not have left it with them.

99 R. X Q. Did you not leave with them a printed copy of the interference record in Sawyer and Man *vs.* Weston?

Same objection.

A. I never saw it in my life. I don't recollect of ever having seen such a copy.

100 R. X Q. Didn't you tell them, or either of them that you were desirous of making an arrangement with the Edison Company by which they should pay you a large amount of money provided you furnished testimony that would defeat the patent now in suit?

Same objections.

A. After they declined to purchase the Flanagan contract, on the ground that it was of no value to them, they requested me to engage in their service, in trying to defeat the patent in suit. I told them that I didn't see how I could be of any service to them, as I had already testified in behalf of Sawyer and Man. Mr. Tomlinson thereupon produced a printed record of my testimony in that case, and he agreed with me that I could not testify in their behalf, so, as to be of any value to them, and he then wanted me to think the matter over and see if I could not see some way in which I

could be of service to them. He said they would pay me handsomely and proposed to hire me by the day, and named as
2299 compensation one thousand dollars a day.

101 R. X Q. Now will you please answer directly whether or not you did not tell them when you went to them that you were desirous or anxious to make an arrangement with the Edison Co. by which they should pay you a large amount of money provided you furnished testimony that would defeat the patent at present in suit?

Same objections.

A. I told them that I had never contemplated entering their service in any such matter, that I had come to them for the purpose of disposing *off* the Flanagan contract, that if they could show me wherein I could be of service to them I should expect to be paid by them very liberally. I do not recollect any sum of money being named.

102 R. X Q. Did you not tell them that your terms were five thousand dollars cash and ten thousand dollars in the event of success, provided you would furnish testimony that would defeat the patent at present in suit?

Same objections.

A. I do not recollect. The whole scheme on their part appeared to be feeling around as to whether I could recollect anything that would be of any service to them, and we separated with the understanding that I was to see them again after trying to recollect whether I could be of any such service, and a few days afterwards I received a telegram from Mr. Tomlinson requesting me to call at their office at a certain hour. I think, 11 o'clock, a. m., on a certain day, I called in response to this telegram, and not seeing either Mr. Tomlinson or Mr. Dyer I left a note stating that I must decline to enter the service of Mr. Edison as I could not see any way to be of service to him in this suit.

103 R. X Q. Going back again to your early interviews with Mr. Tomlinson and Mr. Dyer did you not propose to them for five thousand dollars in cash and ten thousand dollars in the event
2300 of success to furnish them with testimony that would defeat the patent at present in suit?

Same objections.

A. I do not recollect any such proposition.

104 R. X Q. Will you swear you did not make such a proposition?

Same objections.

A. Whatever was said was predicated upon the provision that they should show me wherein I could be of service to them.

105 R. X Q. And upon that predication what was your offer to them?

Same objections.

A. I do not recollect. I told them they would have to pay me handsomely if I could be of any service which I did not then and have not since seen any way of accomplishing. Their proposition was a very great surprise to me.

106 R. X Q. How much did you ask them to pay you for the Flanagan interests?

Same objections.

A. Sixty thousand dollars.

107 R. X Q. And that they declined, did they not?

Same objections.

A. They did.

108 R. X Q. I hand you a typewritten paper and ask you whether the same is not a copy of a statement of facts drawn up in your handwriting and handed by you in manuscript to Messrs. Tomlinson and Dyer or one of them at or about the time of your first interview with them?

A. Without reading it all through I should think it was a copy of this was left by me in my handwriting.

109 R. X Q. And this you left with them at or about the time of your first interview?

Same objections.

A. Yes.

110 R. X Q. From whom did you derive the alleged facts set forth in that paper?

2301 Same objections.

A. From W. E. Sawyer.

111 R. X Q. How many times did Mr. Tomlinson and Mr. Dyer to your knowledge examine the Flanagan drawings at Mr. Schuyler's, or elsewhere?

Same objections.

A. Once.

112 R. X Q. And they refused the terms of sixty thousand dollars?

Same objections.

A. Yes.

113 R. X Q. When did they so refuse?

Same objections.

A. Some time after; a long time after.

114 R. X Q. Independently of the terms of this Flanagan offer, did you not try to make with them an arrangement by which you were to receive five thousand dollars cash and ten thousand dollars in the event of success provided you would furnish testimony that would defeat the patent at present in suit?

Same objections.

A. I never seriously contemplated rendering any such service to the Edison Company.

115 R. X Q. Did you not state exactly the terms I have mentioned?

Same objections.

A. I told them that if they could show me wherein I could be of service, I should expect very liberal compensation, but I do not recollect any amount of money or amounts of money being named; that I had not thought of this subject for a great many years, had then very little recollection, and would rely upon them to refresh my memory upon the subject.

116 R. X Q. Will you swear that you did not name the exact terms I have mentioned?

Same objections.

A. I do not recollect any amounts. It rested in my mind very lightly, as I had no idea of entering their service, and
2302 & 2303 not see how I could be of any service to them.

117 R. X Q. Did you not tell them that the five thousand dollars was necessary to reimburse you for the loss you would sustain, as you were a stockholder in the Consolidated Co.?

Same objections.

A. I might have told them that I was a stockholder, and that the success of their case would destroy the value of the stock which I held in the Consolidated Co.

118 R. X Q. How much stock did you then hold?

Same objections.

A. I have always held about the same. I guess about fifty or sixty shares of one hundred dollars each. I guess I held more. I must have held from fifty to eighty shares. On thinking it over, I think I held about eighty shares.

119 R. X Q. Did you not tell them that you felt bound to reimburse Mr. Schuyler and some other gentlemen as part reason for the amount you demanded?

Same objections.

A. I told them that the only thing I could consider would be a purchase of the Flanagan interest in which Mr. Schuyler was also interested.

120 R. X Q. Again I ask you whether you will swear that you did not demand five thousand dollars cash, and ten thousand dollars in the event of success, provided you furnished testimony that would defeat the patent?

Same objections.

A. I had no idea that I could furnish any testimony that would defeat the patent, and therefore do not see how I could have demanded any money beyond such services as they might designate for me to render.

121 R. X Q. Did you not name five thousand dollars in cash and ten thousand dollars in the event of success?

Same objections.

A. I do not recollect.

122 R. X Q. Did you not call at Mr. Tomlinson's office several times up to about June 30, 1887?

2304 Same objections.

A. I called as often as he made an appointment for me to call. He was never ready to give me an answer in relation to the Flanagan contract. He requested me to call, and call which I did about a dozen times, receiving each time the excuse that he was either too busy, or that the matter had not received sufficient consideration.

123 R. X Q. Did you not at one interview leave your address with him, and ask him to telegraph you when he wished again to see you?

Same objections.

A. I left my address with Messrs. Dyer and Tomlinson the first time I called at their office with these papers. I have no recollection of ever asking Mr. Tomlinson to telegraph me.

125 R. X R. Did you not leave your address and ask him to telegraph you at the occasion of your visit of June 24 or 25, 1887?

Same objections.

A. I don't recollect doing so.

125 R. X Q. Can you say whether you did or not?

Same objections.

A. I remember that I was surprised to receive a telegram the latter part of June from Mr. Tomlinson, so do not think I could have requested him to send me a telegram. He had promised to let me know when he would like to see me again.

126 R. X Q. Did he not telegraph you June 28, 1887, to call at his office the following morning at 11 o'clock?

Same objections.

A. He did.

127 R. X Q. Have you still the telegram?

Same objections.

A. I have.

128 R. X Q. In whose possession is it?

Same objections.

A. At present in Mr. Broadnax's

2305 129 R. X Q. When did you hand it to him?

Same objections.

A. A few days ago, possibly last Saturday.

130 R. X Q. In answer to that telegram you went, did you not?

Same objections.

A. I did.

131 R. X Q. Did you not see Mr. Tomlinson and Mr. Dyer, and have quite a long interview with them?

Same objections.

A. I called, but did not see either of them.

132 R. X Q. You are positive you did not see them when you called in response to that telegram?

Same objections.

A. I am.

133 R. X Q. When did you call again?

Same objections.

A. I called again, a week or so after this, and got the papers in relation to the Flanagan matter that had been left in their hands. I do not recollect ever seeing Mr. Tomlinson or Mr. Dyer again after the receipt of the telegram.

134 R. X. Q. Then you swear positively that in response to the telegram you did not have a long interview with Mr. Tomlinson and Mr. Dyer.

Same objections.

A. I do, and am sure of this, because I left a note addressed to them, or one of them, and took a copy of this note away with me, and I have this copy now in the possession of Mr. Broadnax, with the telegram.

135 R. X Q. Was not that note left July 1st, 1887?

Same objections.

A. Yes, sir; it is dated July 1, 1887.

136 R. X Q. Then you wrote in Mr. Tomlinson's office?

Same objections.

A. I did; in their offices.

137 R. X Q. On the day on which it is dated?

Same objections.

2306 A. Yes, sir.

138 R. X Q. And the time you called in response to the telegram of June 28th, was June 29th, was it not?

Same objections.

A. I am not sure whether I called June 29 or July 1st; I should think I called July 1st, as the note is dated on that day.

139 R. X Q. When did the telegram request you to call?

Same objections.

A. I think it was on the following day.

140 R. X Q. As a matter of fact, did you not call on the following day, June 29th, and have a long interview with Mr. Tomlinson or Mr. Dyer?

Same objections.

A. I have no recollection of calling then. A friend of mine was then laying at the point of death, and he did die, and I was with him most of the time. So I do not think I could have had any long interview with Mr. Tomlinson or Mr. Dyer in response to this telegram.

141 X Q. Did you not on June 29th have a long interview with them and after the interview inform them that you would call again July 1st and did you not call July 1st according to your promise and without seeing Mr. Tomlinson or Mr. Dyer and did you not then leave a letter for Mr. Tomlinson?

Same objections.

A. I do not think I did have an interview with them on the 29th of June, as a postscript to my letter states that I was unable to call on them at 11 o'clock as I had to attend to the funeral of my friend.

142 X Q. Did you not on June 29th, 1887, at the conclusion of your interview make an appointment to call July 1st at 11 o'clock and did you not, as a matter of fact, call on July 1st later in the day and fail to see Mr. Tomlinson and write and leave the letter for him?

Same objections.

2307 A. As a matter of fact I had no appointment to call upon Mr. Tomlinson before I received his telegram and in response to that I did call and failing to see either Mr. Tomlinson or Mr. Dyer I did write in their office a letter which I left for Mr. Tomlinson.

143 X Q. You are positive then that after you received that telegram you never called on either Mr. Tomlinson or Mr. Dyer until the occasion of your writing and leaving the letter July 1st, 1887?

Same objections.

A. I am.

144 X Q. Whether you had a long interview June 29, 1887, or not, did you not about that time have a long interview with them as to the subject of your giving testimony for the Edison Co.?

Same objections.

A. I recollect an interview but not that it was a very long interview.

145 X Q. Did you not at this or some other interview with them state in substance that your prior testimony in the Sawyer and Man interference was false?

Same objections.

A. No, sir. I couldn't recollect what that testimony was. How could I say it was false when I couldn't recollect it.

146 X Q. Then you swear that you did not so state to Mr. Tomlinson and Mr. Dyer or one of them?

Same objections.

A. I do.

147 X Q. Did you not tell them at this, or some other interview that prior to your giving testimony in the interference Mr. Man had dictated to you memoranda of what he had done and had tried to impress you with the fact that you had seen it done, or words to similar effect?

Same objections.

A. I never had but one interview with Tomlinson or Dyer upon
the subject of my employment by them in the interest of Mr.
2308 Edison and I told them that I had no recollection then of
what I had testified in the interference case between Sawyer-Man and Edison.

148 X Q. Now, will you please answer my last question?

Same objections.

(Question re-read to witness.)

A. I answer such question, no, sir.

149 X Q. Do you swear that you never made such statement to Mr. Tomlinson or Mr. Dyer, or either of them?

Same objections.

A. I do.

150 X Q. Did you not tell them of Mr. Man dictating memoranda for you prior to your giving your testimony?

Same objections.

A. No, sir.

Adjourned for lunch.

Resumed after lunch.

151 X Q. Then you are positive that you never mentioned either to Mr. Tomlinson or Mr. Dyer that Mr. Man had dictated memoranda, or have given you written memoranda connected with the subject-matter of your testimony in interference?

Same objections.

A. I am.

152 X Q. And your answer applies to all interviews which you had either with Mr. Tomlinson, Mr. Dyer, or both.

Same objections.

A. It does.

153 X Q. Did you not tell Mr. Tomlinson or Mr. Dyer, or one of them, that Mr. Man had endeavored to impress you with the idea that you had seen what Mr. Man spoke of, or gave you memoranda of, before your testifying in interference.

2309 Same objections.

A. No, sir.
154 X Q. That you will swear positively?

Same objections.

A. Yes, sir.
155 X Q. Did you not tell Mr. Tomlinson or Mr. Dyer, or one of them, at the time of your giving testimony in interference, you were interested in the success of Sawyer-Man, and in testifying, as you actually did, that you were, in fact, merely stating, what had been told you by Mr. Man, or words substantially to that effect?

Same objections.

A. No, sir.
156 X Q. Did you not tell Mr. Tomlinson or Mr. Dyer, or one of them, that at the time of your testimony in interference, you did not have, and at the time you talked with Mr. Tomlinson or Mr. Dyer, you did not have any recollection of having actually seen the things as to which you testified in interference, or words substantially to the same effect?

Same objections.

A. I told them I had no recollection of what I had testified to in the interference between Sawyer and Man and Edison; that it was about ten years ago, and the incidents and facts had passed from my mind.
157 X Q. To what incident and fact do you refer in your last answer?

Same objections.

A. The details and facts that transpired from the time Sawyer left the employ of Flanagan in February, 1878, up to the present time.
158 X Q. Those things you told them you did not remember?

Same objections.

A. I told them I did not remember them.
159 X Q. Please answer recross 156 as directly as possible?

Same objections.
2310 (Question re-read to witness.)

A. I did not.
160 X Q. Do you swear that you told them nothing of that kind?

Same objections.

A. Nothing of that kind. I did not recollect what I had testified to.
161 X Q. You miss the point of my question, which is as follows: Did you not tell Mr. Tomlinson or Mr. Dyer, or one of them substantially that when you testified on interference you testified as to matters as to which you had no recollection?

Same objections.

A. No.

162 X Q. Did you not substantially tell them that your testimony on interference was not given from your own recollection, but from memoranda and suggestions and information given to you by Mr. Man?

Same objections.

A. No, sir.

163 X Q. Did you not tell them in substance that you had been led or influenced to give your testimony by Mr. Man and by Mr. Broadnax, and that the testimony you had so given was false?

Same objections.

A. No, sir.

164 X Q. Did you not offer to testify as to this on behalf of the Edison Company in the New York case, brought against them by the Consolidated Company providing you were paid the amount you demanded?

Same objections.

A. No, sir.

165 X Q. Did not Mr. Tomlinson or Mr. Dyer, or one of them, inform you in substance that they did not wish to be in the position of purchasing testimony, or doing anything that was improper, and that they could not use you and would not use you, if you
2311 were put on the stand without stating just what the arrangement was and how it came about, and that you would have to state on the stand that your previous testimony was false, if the story you were telling then was true, and that this would place you in a very bad position?

Same objections.

A. No, sir; there was no arrangement to explain.

166 X Q. Did not Mr. Tomlinson or Mr. Dyer, or one of them, inform you that the Edison Company would be very reluctant to make any such arrangement as to pay you a sum down and a sum in the event of success, and that they considered it your duty to testify to the truth, whatever it might be, whether for or against them, and that all that could be properly done, would be, to pay you reasonably for such time as you might devote to testifying or procuring evidence, or words substantially to this effect?

Same objections.

A. No. They said they would employ me by the day, and would pay me very liberally to assist them in procuring testimony, and I told them to indicate what services they would require of me, which they promised to do, but I have never seen them from that hour to the present on that subject.

167 X Q. Did you not then make a counter-proposition to the effect that they should pay you twenty-five hundred dollars down

and fifteen thousand dollars in addition, in case of success in defeating the patent at present in suit?

Same objections.

A. No; this terminated the interview.
168 X Q. What terminated the interview?

Same objections.

A. The interview terminated with the understanding that they should indicate to me what services I would be expected to render.
169 X Q. What interview terminated?

Same objections.

2312 A. The only one we ever had upon this subject at the time when they declined to purchase the Flanagan contract.
170 X Q. What was the date of that interview?

Same objections.

A. In June, 1887, a few days prior to the receipt of the telegram which I received from Tomlinson.
171 X Q. Did you not at some time make to them the proposition substantially as stated in X Q. 167?

Same objections; (same read to witness.)

A. No, sir.
172 X Q. Did you not state to them or one of them that the reason of your willingness to take less in cash down and more by way of contingency was because you were entirely confident of success in beating or destroying the Sawyer-Man patent in suit?

Same objections.

A. No, sir.
173 X Q. Did they not reply to you substantially that they could not know the value of your testimony or of information which you represented to them you were able to procure until they knew what it was?

Same objections.

A. No, sir. I had no information.
174 X Q. Did you not represent to them that you had sources of information unknown to them which you could work up, and which you were confident would destroy the Sawyer-Man patent in suit?

Same objections.

A. No, sir. I had no recollection on the subject at the time they spoke to me upon this matter.
175 X Q. Did you not tell them that until they paid you what you demanded you were unwilling to give them further information?

Same objections.

A. No, sir.

2313 176 X Q. Did you not tell them, or intimate to them, that within fifteen minutes you could put them in the way of obtaining information which would destroy the patent at present in suit?

Same objections.

A. No, sir.

177 X Q. Did you not tell them that if you put them in possession of this information you could not be protected, and that they would no longer be dependent upon you?

Same objections.

A. No, sir.

178 X Q. Did you not for these reasons decline to send them further information unless they agreed to your demand?

Same objections.

A. No, sir.

179 X Q. Did they not then ask you whether this proposition would be satisfactory to you, to pay you so much down whatever it might be, for you to make a truthful statement to them, whether they used it or not, and then if they decided to avail themselves of your services, to pay you reasonably for the time you devoted to this service?

Same objections.

A. No, sir.

180 X Q. Did you not then leave without accepting or refusing this proposition, but saying substantially to them that they should ask their company what they thought of your original proposition and demand?

Same objections.

A. No. There was nothing to accept or reject. I left them with the understanding that they would indicate what way I could be of service and from that day to this I have never seen them.

181 X Q. Did you not leave them promising to call again, July 1st, at 11 o'clock in the morning?

Same objections.

A. No, sir.

2314 182 X Q. Did you not as a matter fact, call at their office July 1st, 1887, at a later hour than 11 o'clock in the morning?

Same objections and also that the witness has answered the same question two or three times.

A. Yes. I did call July 1st, and left the letter already referred to.

Defendant's counsel offers in evidence the copy of the statement of alleged facts referred to in cross-question 108 and the same is marked Defendant's Exhibit Church Statement of Facts, April 26, 1889.

Counsel for complainant does not intend to waive his objections or notice of motion to strike out the so-called cross-examination, but insists that the cross-examination has no reference whatever to the examination-in-chief, and that in pursuing the course defendant's counsel has pursued he has made the witness his own, and is not at liberty to contradict him, proceeds to ask the witness a few questions on redirect, and to put in two exhibits, viz: the telegram received by the witness from Mr. Tomlinson, and also a copy of the letter left by the witness at the office of Tomlinson & Dyer for Mr. Tomlinson on July 1st, 1887.

185 R. D. Q. Please to look at the telegram I now hand you and state if you identify it, as the telegram you received from Mr. Tomlinson.

A. I do.

Telegram offered in evidence and marked Complainant's Exhibit Tomlinson Telegram, April 26, 1889, W. T. F., sp. ex'r.

186 R. D. Q. Please to look at the letter now shown you, and state if you identify it as a copy of the letter left by you with Mr. Tomlinson.

A. I do.

187 R. D. Q. Was this copy of that letter made at the time the letter was written in the office of Mr. Tomlinson?

A. It was.

2315 Letter offered in evidence and marked Complainant's Exhibit Church Letter to Tomlinson, W. T. F., special examiner, April 26, 1889.

188 R. D. Q. Referring now to Defendant's Exhibit Church Statement of Facts. Please examine it and state if you recognize that as a copy of one of the papers given by you to Mr. Tomlinson as one of the papers upon which you predicated any statement, you may have made to Tomlinson about the Sawyer-Man patent in your effort to sell the Flanagan contract.

A. I do.

WILLIAM H. CHURCH.

DEFENDANT'S EXHIBIT CHURCH STATEMENT OF FACTS. April 26, 1889. W. T. F., S. E.

January 2nd, 1877. Agreement between Sawyer and Flanagan, in which Sawyer assigned $\frac{3}{5}$ interest in certain patents then already taken out by him, also $\frac{3}{5}$ths interest in a number of inventions contemplated but not patented; also agreed to assign $\frac{3}{5}$ths of all inventions and improvements which he should make during the exist*a*nce of this agreement.

February 15th, 1887. This agreement continued in force until the 15th of February, 1878, during which time Sawyer kept his office with Flanagan in the Coal and Iron Exchange building on Cortlandt street, N. Y. city, where the laboratory for experiments was situated.

In the months of November and December, 1877, Sawyer invented and made full drawings of the improvements and ideas contained in the "Sawyer-Man" patents and fully experimented upon them, testing their practicability, and these original drawings are now in the possession of S. D. Schuyler, No. 44 Broadway, N. Y city.

2316 These valuable discoveries were secreted by Sawyer from Flanagan though he continued in his employ and received his salary weekly till February 15, 1878.

In the early part of February, 1878, Wm. E. Sawyer was introduced to Albon Man, before he had left the employ James Flanagan, and Albon Man was shown all these drawings, fully representing the "Sawyer-Man" patents and went to the laboratory in the Coal and Iron Exchange building, and there saw the experiments made by W. E. Sawyer, showing the practical workings of these inventions.

About February 15, 1878, Albon Man made arrangements with Wm. E. Sawyer and on March 19, 1878, they entered into a written agreement.

See copy of this agreement, as taken from an exhibit in the interference between Thomas A. Edison and Sawyer and Man.

In the month of May, 1878, Albon Man, for the first time, saw the agreement between Sawyer and Flanagan of January 2d, 1877, and discovered that all that Sawyer has which was of any value belonged to the extent of $\frac{3}{5}$ths to Flanagan, and after devising various modes of getting around this agreement, among which was to get a statement from Flanagan of his expenditures and reembursing him under certain provisions of the agreement, Albon Man decided that they could not get rid of the agreement in that way because these inventions had been kept concealed from Flanagan so that he had had no opportunity to decide whether he would accept and patent the invention or not.

Albon Man finally hit upon the mode which was adopted, which was to take out these patents for the inventions as joint inventors, and then the second agreement between W. E. Sawyer and Albon Man was made on the 11th of May, 1878.

See copy of this agreement, as taken from an exhibit in the interference between Thomas A. Edison and Sawyer and Man.

2317 The original drawings made by Sawyer in 1877, before he saw Albon Man, with affidavits made by W. E. Sawyer and also by James G. Smith who was associated with Sawyer in the agreement with James Flanagan, are in the hands of Spencer D. Schuyler at 44 Broadway, N. Y. city, who has the power to transfer all rights, titles and interests in and to the agreement between W. E. Sawyer and James G. Smith with James Flanagan of January 2d, 1877, and the party possessing this will have the right to use these facts, as stated above, against the "Sawyer-Man" patents.

See copy of the agreement between W. E. Sawyer, and James G.

Smith with James Flanagan of January 2d, 1887, as taken from an exhibit in the interference between Hiram S. Maxim *vs.* Sawyer and Man.

As the reason for having these patents issued for a joint invention was to avoid any obligation under the Flanagan agreement.

COMPLAINANT'S EXHIBIT TOMLINSON TELEGRAM. April 26, 1889. W. T. F., Spe. Ex'r.

JUNE 28, 188–.

Dated New York, 16 Broad St., 28.

To W. H. Church, 536 E. 87 :

Please call at my office at eleven to-morrow.

JOHN C. TOMLINSON.

2318 COMPLAINANT'S EXHIBIT CHURCH'S LETTER TO TOMLINSON. April 26, 1889. W. T. F., Spe. Ex'r.

JULY 1, '87.

MY DEAR SIR : Any attempt to prove that Man was not a joint inventor with Sawyer on the ground that he proposed himself as a joint inventor to avoid Sawyer's obligations to Flanagan will be met by the question : whether the obligations between Sawyer and Flanagan were ever of any interest to Edison or to his company, and if not, then how do they become relevant to their interests now?

On reflection, I have decided not to engage in Mr. Edison's matter, as I do not see my way clearly to be of service to him.

Yours, &c., W. H. CHURCH.

P. S.—Have to attend the funeral of an old friend this morning so could not be here at 11. I will call on you next Tuesday at 11 a. m. for the papers which were left in your hands when these negotiations commenced.

Yours, W. H. C.

2319 NEW YORK, *April 23d*, 1889.

Met pursuant to notice.

Present, Mr. Broadnax for complainant, and no one for defendant.

Amos Broadnax Recalled.

AMOS BROADNAX of counsel for complainant being recalled testifies as follows:

The statement made by me on the record following the answer to question 34 of Mr. Church's deposition is true of my own knowledge, said statement referring to Complainant's Exhibit Rockwell-Kent Letter produced by said Church in his deposition.

I desire to say further, that on or before January 7, 1888, I, as counsel for the Consolidated Electric Light Company, retained Wm. Hochhausen as electrical expert, and gave him a general retainer for services to be rendered by him as such expert for the Consolidated Electric Light Company, the sum of two hundred and fifty dollars, as appears by his voucher for that amount of money on that day, the said voucher being in the words and figures following:

"$250. New York *Jan'y* 7, 1888.

"Received of Sawyer-Man Electric Co. two hundred and fifty dollars in full, general retainer for services as expert for Consolidated Elictric Light Co.

"WM. HOCHHAUSEN."

The foregoing is a true copy of said voucher; the said Hochhausen being retained to testify as an electrical expert, and for no other purpose, and he was under such retainer when he was called to testify for defendant herein.

Mr. Lowrey appeared for defendant and waived cross-examination.

AMOS BROADNAX.

2320 New York, *April 22nd*, 1889.

Met pursuant to notice.

Present: Mr. Broadnax for complainant, and Mr. Donnelly for defendant.

Testimony of Edward Berry.

Edward Berry, a witness called on behalf of complainant and duly sworn, testifies as follows:

1 Q. What is your name, age, residence and occupation?

Edward Berry, 41 years of age, I live at Rutherford, N. J. I am manager for a fishing-tackle house, J. B. Crook, of New York. Their place is at 50 and 52 Fulton street.

2 Q. Were you employed by them in the year 1878?

A. Yes, sir.

3 Q. Are you acquainted with Albon Man?

A. Yes.

4 Q. How long have you known him?

A. To the best of my knowledge for at least twenty-five years.

5 Q. State whether or not you have furnished Mr. Man with any kind of woods.

A. Yes.

6 Q. State if you knew what use Mr. Man made of such woods.

A. No, sir; not at the time he got the sticks from me.

7 Q. Please to give the names of the different kinds of woods you furnished him, and furnish specimens of the woods, if you can do so.

Objected to as immaterial, irrelevant and incompetent.

A. He took every kind I was using: logwood, lancewood, hickory, greenheart, bamboo. I have with me three kinds: lancewood, greenheart and bamboo, all of which I produce.

Specimens offered in evidence and marked respectively "Complainant's Exhibits Lancewood Produced by Berry, Greenheart Produced by Berry, and Bamboo Produced by Berry, W. T. F., special examiner, April 22, 1889." 2321

Said exhibits objected to as immaterial, irrelevant, and incompetent.

8 Q. State, if you recollect, when it was that you furnished these woods to Mr. Man.

A. It was in the fall of 1878. It was either in September or October, I won't say emphatically which month or which day; but it was within one of those two months.

9 Q. Where did this bamboo come from?

A. It comes from China; we call it Calcutta bamboo to distinguish it from Japanese bamboo.

10 Q. Where did the bamboo come from that you furnished to Mr. Man in 1878?

Same objection as to 7th question.

A. It is Calcutta bamboo, same as the exhibit.

Cross-examination by Mr. Donnelly.

8 X Q. How long have you been in the employ of J. B. Crook?

A. Since 1859.

9 X Q. What was your position with J. B. Crook in the year 1878?

A. Manager.

10 X Q. Manager of what?

A. Of the business.

11 X Q. What did that include?

A. Buying and selling of goods and taking care of the business financially.

12 X Q. How extensive a business did you do at that time?

A. Doing a business of about twenty thousand dollars a year.

13 X Q. Where did J. B. Crook then reside, and where does he now reside?

A. He then lived at Rutherford, N. J. He is dead.

14 X Q. In whose employ are you now?

2322 A. Of his estate.

15 X Q. When did you first become acquainted with Albon Man?

A. I am sure that it was as early as 1870.

16 X Q. Where did you first become acquainted with him?

A. At No. 50 Fulton street, New York.

17 X Q. Did you know him personally and intimately in 1878?

A. Yes.

18 X Q. Did your acquaintance arise simply in the course of dealing or selling him goods?

A. That is all.

19 X Q. You simply knew him in 1878 as you did other customers to whom you from time to time sold goods?

A. Yes, sir.

10 X Q. These woods which you speak of as having furnished Mr. Man in 1878; did you sell them to him or did you give them to him?

A. I gave them to him.

21 X Q. When was your attention first called to the fact of your having given these woods to Mr. Albon Man after you furnished them to him as you have stated and by whom?

A. I think it is about 18 months ago by Mr. Man.

22 X Q. Between the time that you furnished the woods in 1878 and 18 months ago, when you say Mr. Man called your attention to the fact, had your attention been directed to the circumstance that you had furnished such woods to Mr. Albon Man as stated?

A. No, sir, not before that time.

23 X Q. I suppose that you hadn't thought about it after you let Mr. Man have the woods until he called your attention to it about eighteen months ago.

A. I hadn't thought anything about it; no, sir.

2323 24 X Q. The fact that he obtained such woods of you had not been a matter of consideration or reflection after you let him have the woods in 1878 until he spoke to you about it?

A. No, sir.

25 X Q. Mr. Man, you say, called your attention to the fact that he had obtained certain woods of you about eighteen months ago. Did he then state what woods he got of you in 1878?

A. Mr. Man asked me if I remembered giving him some pieces of wood, and I told him yes.

26 X Q. Did Man state to you at that time what wood or particular woods he had obtained of you in 1878?

A. I don't think he did.
